Potentilla nepalensis Willmottæ, so brilliant in cherry-red, gold, and jet, so willing and neat in habit, might claim a foremost place in this list. Geum Borisii must also be squeezed in, and in flaxes a large number of claimants has to be reduced to two, viz., Linum arboreum and L. narbonense. Æthionema Warley Rose, positively dazzling in the intensity of its rose-carmine, stands a long way ahead of any other of its race, an ideal rock garden plant of the utmost loveliness.

Erodium chamædryoides has won the affection of everyone who knows it, its simple charm and sweet temper together having raised it to the distinction of being a "treasure," a position that even its lovely rose-pink sister will never be

Digitized by Google

able to usurp. Into the region of campanulas I hesitate to enter for obvious reasons, but among the better known ones the ever-delightful C. pumila, in one or other of its exquisite varieties, and any good form of C. Portenschlagiana must always rank high in any selection of this kind. C. garganica W. H. Paine, C. Profusion and C. Haylodgensis comprise a trio of well tried favourites that one can never be without and never need be for all are plants which anyone can grow to perfection.

Erysimum linifolium must always be included among the standard rock plants, and the milk-white Hutchinsia alpina has not, I think, a rival in subjects suited to its purpose. Again, where bolder masses of purest white are desired, can anything excel Iberis corifolia or a good form of I. sempervirens? These have never been surpassed, or, indeed, equalled; in their own way, and in their own sphere, and in colour they hold the same relative position that Alyssum saxatile holds among golden yellow subjects of like size and habit.

Viola cornuta in all its varieties is an old thing of sterling merit, whose excellent qualities we are sometimes apt to over-look these days, and another "stayer" among these bigger things is the double-flowered Arabis albida. In spite of their tendency in some places to develop habits a little too healthy, Helichrysum bellidioides and the double-flowered Cardamine pratensis, are both invaluable plants which need fear no rivals, and I would like to include here, as the easiest and most beautiful among the best of its class, Omphalodes cappadocica.

Lithospermum prostratum, var. Heavenly Blue, cannot be omitted and, bearing in mind that at least half my points are being awarded for general garden merit and usefulness, Saxifraga Wallacei stands head and shoulders above a host of others of its kind. So would I more willingly part with many a gallant Pompadour or Red Admiral than have to lose those neat and close-set mats of S. moschata atropurpurea, or Stormouth's variety of the same thing. For similar reasons I often have a friendlier eye for the frosty-grey cushions of S. valdensis, or the bristling, limy rosettes of such good tempered creatures as the more familiar Aizoons and one or two of those better known, medium sized members of the Cotyledon or pyramidalis set, than I have for the more troublesome, if perhaps more distinguished, scions of this enchanting race. In its own way Veronica prostrata (Teucrium dubia) is unique, a plant which in all-round usefulness stands alone among its kindred, while its beauty is beyond comparison. The golden-leaved form, var. Trehane, with china-blue flowers, might be bracketed with the above, for it also holds a place of notable distinction. These two, with V. gentianoides to make a third, belong to that goodly company of invaluables which time does not wither nor custom stale, yet not a few of us seem scarcely to realise it.

A. T. JOHNSON.

THE ELFIN GRACE OF VIOLA GRACILIS MAKES IT INDISPENSABLE.

JOHN RICHARD ANDERSON, J.P

HIS GARDEN DIARY, 1745. A NOTE BY THE HAND OF DION CLAYTON CALTHROP.

YOU must, if you please, keep this picture in your mind. There is a fire in Mr. Anderson's study owing to a hint of frost in the air, just enough frost to cause the logs to burn blue flame now and again. He is a man of about fifty with a face of classic mould, a Roman face not uncommon in England. His coat is wide-skirted and his wig is a bob major, ruffles of fine lace adorn his wrists and his neckcloth is from Ypres. By him on the hearthrug lies his pointer, Don, his nose on his paws, his mind in wet turnip fields where is a covey of partridges.

On a large table lie two books of manuscript neatly written in the Italian hand: the one closed is Mr. Anderson's "Bee Book," in which he has just noted "By this time your Bees sit; keep them close Night and Morning." The open book is his "Garden Book," in which he keeps notes of his parterre and garden, together with garden lore. He notes such things as the origin of the name of the Jerusalem artichoke, which is Italian and a corruption of gir a sole, to turn to the sun; and alongside he notes that the heliotrope does likewise, but is so called from the Greek: helio tropos.

"I favour the old names," he writes, "and I am pleased my gardener, James Spalding, should use them. Though in other ways he is a silent man he talks to children, animals and flowers. Yesternoon he told me five names for the Pansy to which I did add a sixth, Pensé for a thought, yet he would have none of it. Herb Trinity he calls them, and Three Faces under a Hood, and Love in Idleness, Stepmother, and Hearts Ease. A peasant will make his Poetry out of the Earth however hard times may be. It is from him my housekeeper has the knowledge to knit stockings of three colours in wool learnt from a pedlar out of Scotland, who gave him also the country name of Venice Mallow, which is 'Goodnight at Noon.' A pretty conceit and true."

Mr. Anderson's spelling is not all it might be, and he likes a flourish to his capital letters, but he is a true countryman and can find his way by the stars and knows the use of simples, and grows all manner of wild things in his garden in a wilderness he keeps. Here he will have celandine and shepherd's purse, sauce alone and rocket, which he calls dame's violet; and he grows balsam, which is touch-me-not; and here also are penny cress and traveller's joy, which is old man's beard or lady's bower.

He hesitates whether to put down "The Cure for a Cough" in his Bee Book or among his Garden Notes. Finally he decides for the Garden Notes.

Told me by Mrs. Crocker (æt. 81) To ease a troublesome cough.

Syrup of Horehound	1 oz.
,, ,, Poppies	1 oz.
,, ,, Squills	1 oz.
Clarified Honey	1 oz.

Two teaspoonfuls to be taken on going to roost, and rising, in a teacupful of warm water, or during the day if the cough be troublesome.

Digitized by Google

Among Mr. Anderson's notes are many such entries as these, cures for toothache, a mixture called "Live Long," "To make Durable Ink," "To Pot Mussels," etc. Here is one for the preparation of "Lavendar Water":

One quart of the purest rectified spirits of wine.
Two oz. of the best oil of Lavendar. (The English extract.)
Two oz. of Bergamot.
Four grains of Musk, if liked.
Half an oz. of the essence of Ambergis.

To be mixed all together and kept well corked in a warm place and repeatedly to be shaken up. It will be fit for use in a month, but if kept a year is much better. (Note. Excellent good. J. R. A.)

We may make sure that all the good man's linen lies in lavender, and that his bowls are full of pot-pourri.

Outside in his garden room, which knows the scent of tobacco and iced punch well enough, we can see him take a survey of his red-walled property with its well ordered walks all box edged, the kitchen herbs out of sight in a garden of their own, the bees humming as they work, the rooks cawing in the elms, the sound of shears as they clip the yew hedge. It is permissible here for Mr. Anderson to divest himself of his wig and wear but a silk scarf to hide his shaven head.

Mr. Anderson, as one can see from his Garden Diary, has little use for the town. "There is not," he writes, "a pair of Red Heels to be seen within ten miles of London. We have no place for them here be they on the shoes of Rakes or Dappers, Pretty Fellows or Politicians. And I wonder if I should care to see Phœbus self in Petticoats parading on the lawn. Your Beauty plucks at flowers so carelessly even to cull herself a Nosegay that she nip off the head of a rose take one sniff at it & throw it away. As for Sir Pertinax Hatton, the fellow when he paid me a visit poked about my flowers with his cane as if they grew of themselves without tending quoting meanwhile some rubbishy verses on the Dullness of the Country. 'Stap me!' the puppy said. 'I protest you are all mould here.' (Note: I gave him some French Claret which had gone a little sour telling him it was of the finest which he declared to be so. And it was good enough for any Jack-a-napes even though his father be My Lord Judge and what-not."

I read further and find great rest and refreshment in the record of this country gentlem[illegible]'s peaceful and orderly life, and I quote here another note [illegible] his:

Came yesterday a great lumbering [illegible] low out of the Fens in the neighbourhood of Whaplode, a regular Gaby in a smocked frock. I was reading Juvenal when Polly, the maid, told me one Samuel wished to speak to me. Anon came this raw countryman twisting at his smock and grinning like a dead sheep. It seemed he claimed a right of coarse fishing in certain Drains as we call them and brought for his payment of fee a hare (which he swore he had found) some golden plover and an old bone box, very dirty, which he told me he had fished up.

I told him he was no better than a Poacher, at which he burst forth into lamentations as said he had been proclaimed as such, but if fish would come to his hook and hares die by his feet and plover flew in at his window what was a man to do. I rated him soundly and told him he was a bad case and that the law was made to see to such persons as he, after which I bade the maids to give him bacon and ale having called them by whistling which is a habit I have.

(Note: To cook golden plover. Captain James recipe.)

(Note: To keep flies out of your rooms in Summer place on the Sills pots of Sweet scented Musk which they utterly abhor so Miss D. L. told me, as also to place India Muslin over your outdoor meat safe against Blue-bottles.)

Mixed with these notes are Thoughts on Religion, all of the kindly charitable character which breathes through this country gentleman and flavours all his meditations. There are bird notes also, as

April 8th. The first swallow doth appear to grace the sky, anon will come plenty and as pretty a sight as winter dimmed eyes could wish for. Sea Gulls come far inland betokening foul weather at sea. They come into my garden and will eat a mess of toast keeping away the lesser birds all but the Starlings who thieve pieces from them.

April 12th. I have a thrush who works for me in my garden breaking snails upon a stone afterwards eating them and then giving praise to God from the topmost bough of a tree.

May 2nd. Come a sweet little maid to see me with a basket of eggs from my friend Lady Sarah Thorpe. Gave her a kiss and some comfits. The pretty Innocence of children is a Delight to the Heart.

I will leave these notes now and continue later with such cullings as may interest my readers.

THE FLOWERING DOGWOODS

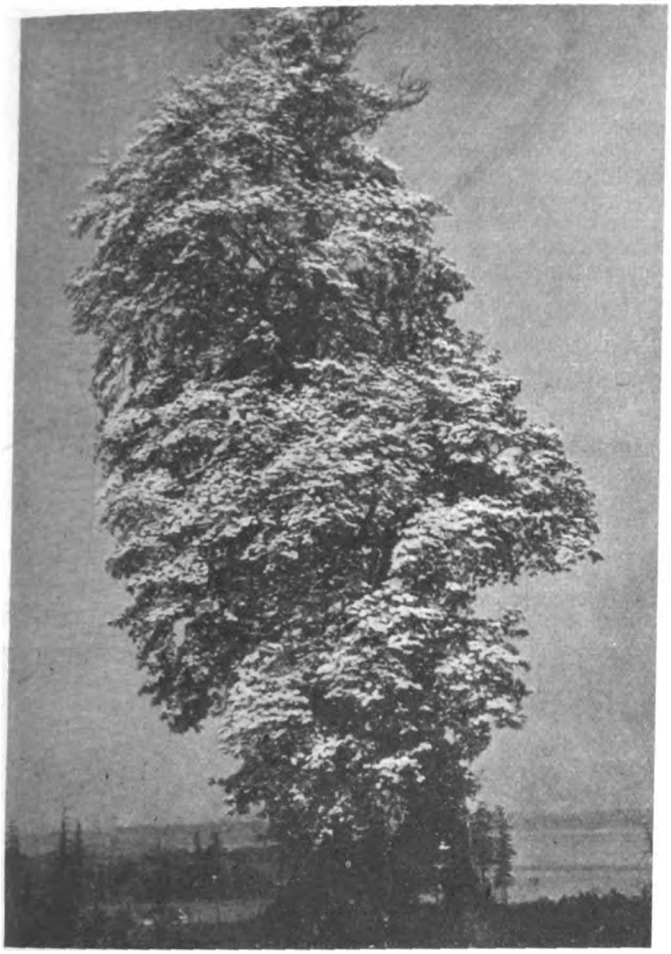
BY E. H. WILSON (*Arnold Arboretum*).

IN the woods and copses of the Eastern United States there is no more lovely tree than the Flowering Dogwood (Cornus florida), the envy and despair of English gardeners. There is no more strikingly handsome flowering tree in the temperate forest of the Northern Hemisphere than the wonderful C. Nuttallii of western North America, sometimes eighty feet tall, with white chalices 6ins. to 9ins. across, so abundant as to drape the crown, and the tree stands out in the spring a gigantic surplice, in the autumn a flaming pillar in the dark forests of Vancouver Island. The bunchberries (C. canadensis and C. suecica), the diminutive brothers of these remarkable trees, are not one whit less lovely nestling on rocks and starring with white the floor of our northern forests. These dogwoods, or cornels, with two Asiatic relatives form a characteristic group in which the flower-clusters are guarded and surrounded by large, handsome white bracts. In this group the conspicuous bracts are the floral feature and the tiny flowers agglomerated into a central button-like mass may be ignored.

To those familiar with the woodlands of eastern North America from Massachusetts southward, any description of the flowering dogwood is unnecessary, but less fortunate folk are entitled to consideration. This dogwood is a slender tree from 15ft. to 40ft. tall, common as an understory in thin mixed woods of

CORNUS FLORIDA GROWING WILD ON THE MARGINS OF WOODS IN NEW ENGLAND.

Digitized by Google



A SEVENTY FOOT TREE OF CORNUS NUTTALLII ON VANCOUVER ISLAND.

deciduous-leafed trees and has a thin airy crown, flattened and often in tiers. If examined in the autumn or winter the branches will be found to be dotted with grey, rounded studs. As spring advances these swell and expand into a cross of bracts, snow-white, from 4ins. to 6ins. across at maturity, becoming stained with pink as they age and fall. So freely are the white crosses produced that the woodlands in May when viewed from vantage points are filled with seemingly floating drifts of purest white suggesting droves of white butterflies hovering and flitting amid the trees. The story of the winter's severity in New England is told by the degree of perfection of the floral bracts of C. florida, and its brilliantly tinted red to crimson passing to pink foliage ushers in the glory of autumn.

Not every year is this dogwood full of flowers. The trees are apt to overdo themselves and need an off year to recuperate and often, especially in Massachusetts, the winter frost may be so severe as to cripple or destroy the flowers. But in good seasons, such for instance as the spring of 1924, the blossoming of C. florida is an event to be classed among the floral spectacles of the world. Visitors from other lands are captivated by its beauty and yearn to possess it. One spring, it was that of 1913 if memory serves me rightly, it was my privilege to walk round the Arnold Arboretum with Sir Herbert Maxwell, distinguished by his many accomplishments and none more so than the charm of his writings on plants and gardens. Said Sir Herbert with a sigh at the close of our peregrinations, "Give me your dogwood, the rest you may keep!" But he knew full well this was impossible for since 1730 this dogwood has been known in England where efforts to grow it successfully are unavailing. Here and there a flowering specimen is known, but insufficient summer heat more than the changeful spring weather is the cause of its failure under English skies. Its exquisite autumn coloured foliage has been spoken of, but its fruit is worthy of praise. Teat-like and clustered several together, scarlet and erect it stands jewelling the branches in the fall.

The variety rubra with rosy red bracts is in great demand though to my mind less lovely than the type. But rightly placed, say on a slope above a pond and viewed across the waters in which its flowers are reflected, it is wondrously beautiful. Close inspection of the flowers is apt to lower the high opinion thus formed since it will be seen that the bracts are only too often more or less malformed. It is claimed that all the plants in cultivation have originated by vegetative propagation (mainly by grafting) from one individual discovered about 1880.

The related C. Nuttallii of Vancouver Island and south to California is a much larger tree, sometimes 80ft. high, with a heavier, elongated crown and with heads of bracts from 6ins. to 9ins. across, expanding with the leaves, similar autumn tints and equally brilliant scarlet fruits. Fortunately, this tree of marvellous beauty can be grown in the South of England where its needs are understood. It flowers freely at Kew though there is scarce a hope of its emulating its pristine glories.

These North American dogwoods have their counterparts in Eastern Asia, where two species grow wild from the central Himalayas eastward through China and Korea to Japan, but with these differences. The fruit is a conglomerate strawberry-like head and the flower-bracts unfold after the leaves expand. They are small to moderate-sized, flat-topped trees. That of the Himalayas and southern and western China (C. capitata), is known as the Strawberry-tree. It has pale yellow, passing to cream-coloured bracts and rather thick, leathery leaves which assume no marked autumn tints. Naturally it is tender and suited only to the climate of the Cornish Riviera and equally warm climates. The other species (C. kousa), distributed from Central China north-eastward through Korea and much of Japan, however, flourishes in England and is also perfectly hardy in Boston, Mass. In the Arnold Arboretum its flowers are of greater bud hardiness than the native C. florida and in consequence it is an even more valuable garden plant. It has this advantage in winter that its flower buds, though formed in the autumn, are folded within a pair of ordinary foliage leaves and have therefore additional protection. C. kousa does not flower until mid-June or later and its upstanding heads on rigid slender stalks have a foil of rich green leaves below. Thus, though these dogwoods of North America and the Orient are close relatives, they are very dissimilar as garden plants and blossoming at different seasons there is

ONE OF THE FINEST OF ALL FLOWERING SHRUBS, CORNUS KOUSA CHINENSIS.

Digitized by Google

room for both and no necessity for invidious comparisons. The floral heads of C. kousa are abundantly produced, from 5ins. to 6ins. across and last for more than a month and finally become pink before they fall. The form from Japan to which the specific name belongs has been sparingly in cultivation in the west since about 1860. The Central China type (var. chinensis) it has been my privilege and good fortune to add to gardens. In this the bracts are larger and broader and often overlap to form a closed, flattened involucre around the button-like mass of real flowers. Some experts acclaim this the finest gift of China to western gardens. Certainly it ranks high in the realm of beauty among hardy flowering trees and its fortunate introducer is proud of the opinion its merits have won for it. In the not distant future this Chinese dogwood will be in great demand.

The red strawberry-like fruits of the Oriental dogwoods are from ½in. to ¾in. in diameter and very attractive in the autumn suspended among the vari-tinted, often vinous purple, foliage. They are edible and the orange-coloured, sweetish pulp is quite palatable, though in it are imbedded several large, hard, stony seeds.

It would seem a far cry of relationship from trees 30ft. to 80ft. tall to lowly herbs a few inches high. But a glance at the flowers shows that it is very close between the bunchberries of North America (C. canadensis), of Europe and Northern Asia (C. suecica), and the flowering dogwoods. For shaded rockeries, woodlands and sheltered nooks there are no prettier little plants than these bunchberries, howbeit rather coy of naturalisation unless they find soil and situation to their liking.

(Photographs by permission of the Arnold Arboretum.)

FLOWERS OF TO-DAY AND TO-MORROW

A DISCUSSION OF THE VARIOUS ASSETS THAT GO TOWARDS MAKING SOME PLANTS UNDOUBTED FAVOURITES

A PERENNIAL subject of discussion among gardeners involves the reasons which underlie changes of gardening fashion, and, especially, the "ins and outs" of popularity of different plants. The *style* of our gardens is necessarily influenced a good deal by the architectural character of our homes; and the way in which we lay out our gardens will, naturally, affect the kinds of material we use to adorn them. The formal parterre called for plants of little individuality, but which would give massed colour effects; the modern wild garden demands the use of kinds suited in appearance to the environment and able, if not to naturalise themselves, at least to hold their own in a plant association consisting very largely of native "weeds." Of late years, wild gardens and gardens largely composed of native plants have been coming to the fore, indicating a change of fashion on the part of certain garden lovers.

We can thus place a finger very quickly on one cause of changing flower fashions, and another and more potent cause is not very far to seek. A new "break" in any flower readily amenable to cultivation at once arouses interest, and, should the "break" prove the forerunner of a steady progressive improvement, interest develops into enthusiasm, and something in the nature of a boom sets in. Once this condition is reached, enthusiasm is likely to be maintained or even increased until the periodical improvements become noticeably less important and ultimately dwindle to insignificance.

GODETIAS, WHICH OF LATE YEARS HAVE ATTAINED A LARGE MEASURE OF POPULARITY, ARE EXCELLENT FOR MASS PLANTING.

THE CASE OF THE SWEET PEA.

Let us consider the case of the sweet pea, which, though still largely grown as a decorative climbing annual, has lost the prominent place in gardening politics which it held but a very few years ago. The late Silas Cole noted and isolated a "freak" plant with flowers all showing greatly enlarged and wavy standards, and it was found possible to perpetuate this very elegant "freak" from seed. The waved standard, by interbreeding, was produced on flowers of various tones of colour, and year by year quite new departures were exhibited. Interest in the flower quickened and, with it, better cultivation became the rule and the possibilities of the flower came to be realised. As the range of colouring extended, moreover, folk began to talk of the possibility of golden yellow and sky blue varieties materialising. There seemed, indeed, to be almost boundless scope for improvement, and the sweet pea rapidly became a "rage." After a time, however, and when every tone of colour and every hue previously known in the flower had been produced in flowers showing a wavy standard, and the pure yellow and sky blue varieties were still as far off as ever, it became obvious that the cycle of improvement had almost run itself out, and interest rapidly fell away. This is hardly the place to discuss the why and the wherefore of this full-stop to progress, but the fact should be noted that, barring a natural "sport," often due to what biologists call the "dropping of a factor," there is a very finite limit to what can be produced by the hybridisation of any particular group of species, and, when once that limit is reached, only the introduction of entirely fresh "blood" can prepare the way for further advance.

The story of the rise, fall and rehabilitation of the dahlia follows the same lines, but in this case the way of advance was definitely baulked by the old-time florists, who were unwilling to let the plant demonstrate its inborn powers of evolution. Every seedling which was found wanting as a show or fancy variety (or, later, as a "cactus") was ruthlessly doomed to the bonfire. The last word was said—for a time—and the dahlia faded out of popularity. But, later on, in the hands of raisers with more catholic tastes, it has taken a higher place than ever in the esteem of gardeners. And this because the newer introductions are admirable for border decoration as growing and equally desirable as cut flowers for indoor

Digitized by Google

decoration, whereas the older exhibition types were primarily flowers of the show bench.

The sweet pea and the dahlia do not stand alone. The rise and fall might easily be traced of regal, fancy and zonal pelargoniums, of the old-time florist's pink, of the auricula, hollyhock and many other flowers. But to what end? Disease may, in some cases—as with the hollyhock—have been largely responsible for a fall from popularity; but, apart from this very natural reason, the main story is in every case the same: popularity follows new developments, and with stagnation comes a fairly rapid fall from favour.

THE DEVELOPMENT OF THE ORIENTAL POPPY.

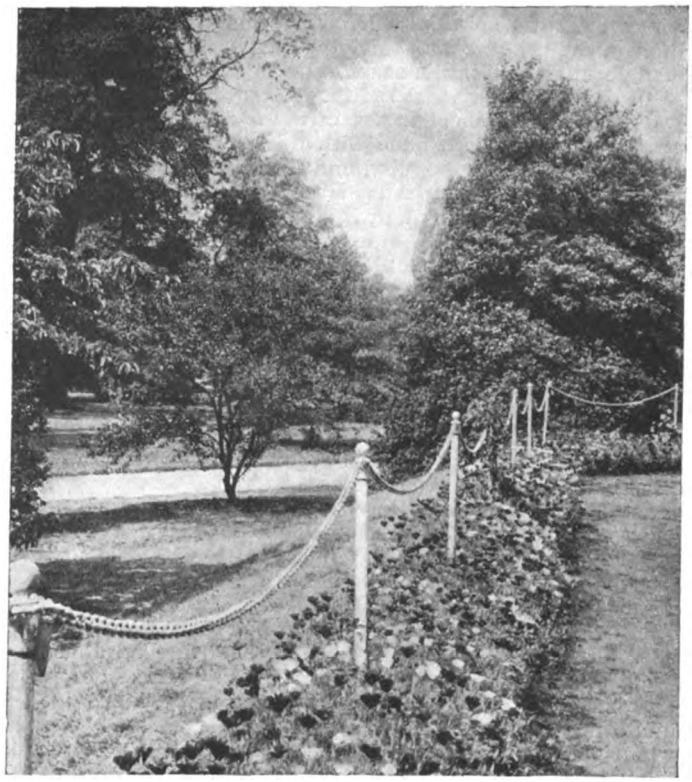
Equal degrees of development do not, however, of necessity involve accessions of popularity, even when beauty of form and colouring seem on a par. Immense improvements have of late years, and until quite recently, been made in the Oriental poppy. The flower is at once showy when massed and beautiful in its colouring and the arrangement of its parts. The plant is easy to cultivate, and its blossoming time comes when flowers are none too plentiful. All this notwithstanding, the Oriental poppy has never had the vogue of the sweet pea, and it is fairly safe to say that it never will have; and this for several reasons. Oriental poppies are desirable as cut flowers only when the severed ends of the stems are treated with boiling water or an efficient styptic; sweet peas may be gathered and placed straight into water. Poppies are not fragrant; *some* sweet peas, at any rate, are. Poppies take a considerable amount of ground space per plant as compared with the more popular flower, and their flowering season is shorter. Yet, in my judgment, these are but minor reasons for the immense difference in the respective degrees of popularity of these two flowers during their own particular boom periods. The principal advantage of the sweet pea was that it could (and can) be *sown to flower abundantly the same year.*

A plant, to be everyone's favourite, must be capable of being flowered in perfection at short notice, and this, in practice, seems to give great advantage to plants of annual duration and to bulbous kinds, using "bulbous" in its broadest sense to include plants which lay up underground reserves and may readily be dried off and planted in that condition, whether the method of storage is by means of bulbs properly so-called, or corms, or tubers.

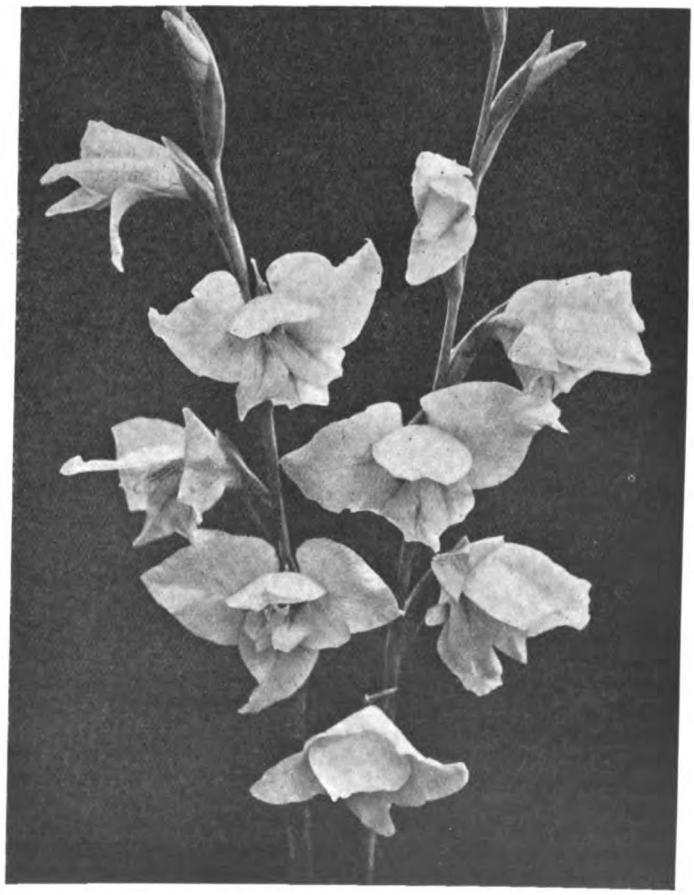
Bearing these facts in mind, let us now consider the probable trend of flower fashions in the immediate future. The bearded iris has had quite a run of popularity, which is likely to continue a while longer, and it can be flowered—if not flowered to perfection—the first season after planting. It is, however, most effective when massed, and the flowering season of any particular variety is not a long one. No startling new development would be likely, then, to give it the popularity once enjoyed by the sweet pea, and, in point of fact, no remarkable developments are to be expected.

THE PLANT OF THE FUTURE.

Very different is the case of the gladiolus, which may be regarded as *the* flower of the immediate future. One may plant corms at Eastertide and have an abundance of first-quality flower the same season, and the progress achieved with the flower since the introduction of G. primulinus about the beginning of the present century, has been phenomenal. The primulinus hybrids are wonderfully free to flower, splendid for indoor decoration and, to the best of my belief, winter-hardy in almost any part of Britain, though, owing to their rapid rate of increase, the corms should be lifted at least every second year. Their freedom to flower may be gauged by the fact that some corms will produce, in suitable soil, as many as seven flower-spikes in a single season, and one year's spawn will often blossom the next. For indoor decoration, the spikes need not be cut until the lowest flowers have faded and the spike is getting a little dishevelled. Even then, if the faded blossoms are removed each morning and the spikes shortened accordingly, they will provide most effective decorative material for some seven to ten days. By successive plantings and, to a smaller extent, on account of the habit which the corms have of throwing side spikes, they may be had in blossom from the latter part of June till the end of October, or even later. Further developments are in store for some few years yet, even if the many fine species recently introduced or re-imported



WITH THEIR LONG SEASON OF FLOWERING AND FREEDOM OF BLOSSOM ESCHSCHOLTZIAS ARE ONE OF THE MOST VALUABLE ANNUALS.



THE GLADIOLUS, THE FLOWER OF THE IMMEDIATE FUTURE.

Within the last twenty years the rise of this flower to fame has been rapid and phenomenal.

Digitized by Google

from South Africa do not allow the hybridist to produce entirely fresh and desirable breaks, which they may, or may not, do. I think, then, that we may safely predict the rise of the primulinus hybrid gladioli in the near future to a popularity rivalling that of the sweet pea at its zenith.

From the gladiolus one naturally turns to the montbretia. Great things have been done with this flower of late; yet it has not become really popular, and I do not fancy that it will. To begin with, the colour range is restricted, and, although the spikes continue long in flower, it is seldom that more than two expanded and unwithered flowers will be found at one time on one inflorescence. The plant is finest when boldly massed and seen from a distance, and from such a point of view the necessary lifting of the corms each autumn is a serious drawback.

Now, what of bulbous plants proper? The lily is a flower for the man whose very soul is in his garden. It needs real knowledge and understanding to cultivate successfully any but a few of the commoner species. All keen gardeners, then, will, as heretofore, grow lilies; but we shall see no "lily boom." The Darwin and other May-flowering tulips will continue to charm us from many a bed outdoors as well as in the conservatory and, as cut flowers, indoors; but no advance is to be looked for in this field, and they should scarcely make further headway. The narcissus is in a different case; further advance with the different sections is made manifest year by year, and an even wider popularity for this most favoured of spring-flowering bulbs may be expected. Among bulbs for cultivation under glass the freesia has shown an immense improvement during the last two decades, and its steady increase of popularity should continue yet awhile. The lachenalia, too, is rapidly doffing its workaday attire and becoming a gorgeous, as it has always been, and easy plant.

Among what are generally accepted as annuals, progress is most apparent at the moment among the eschscholtzias, godetias and clarkias, the first-named and the last being excellent for cut flower. The eschscholtzia is by far the most useful of the trio, owing to its long season of flowering and its freedom to blossom, and its colour range is wide and still extending.

When we come to perennials, we have to note a number of very popular plants from quite dissimilar genera—a couple of geums, a brace of potentillas, an anchusa or perhaps two, a few campanulas, Thalictrum dipterocarpum, the double form of Gypsophila paniculata, and so forth. It is very probable that there will be additions to these sporadic "stars," but it is less easy to predict whence they will materialise. Of *strains* of flowers, the delphinium has made most progress of late, with the lupin a good second, if we except the iris, already referred to. Both larkspur and lupin may be expected to attain still greater measure of popularity; but the ubiquitous and useful herbaceous phlox seems already to be commanding less attention, and the same may be said of our old friend columbine, Latinised into aquilegia. There are evident signs of a revival in interest in the bunch primrose or polyanthus, though, to the best of my belief, the finest strains in existence to-day fall far short of the best of thirty years ago.

And now, as we turn to shrubs, we come to our national flower—the rose—the popularity of which none can doubt. Whether it will continue to do so depends upon the successful launching of new "breaks," and these may be expected, for the world's rose raisers are an alert set of men.

The increased popularity of flowering shrubs in general may very largely be attributed to a cutting down of costs after the war, and, as complete recovery is likely to be long delayed, the shrubs will doubtless stay long enough to be properly appreciated for their own sakes. If I might pick out a family which is likely to meet with great and greater favour, I would select the broom, with its great possibilities of hybridisation.

We may expect, then, a continuation of popularity for flowering shrubs, and particularly for the rose, and immensely increased attention may be forecasted for the gladiolus and dahlia, with very considerable accessions of strength to the bands of devotees who favour the daffodil and the freesia.

R. V. G. W.

SOME NEW CARNATIONS

THE choice of the best varieties of carnations, both in perpetual and border kinds, depends to a certain extent on personal taste, but such points as shape of the flower, quality, splitting of the calyx, length of the stem and lasting properties are agreed upon by most people. Some prefer a variety with a good perfume, others aim at producing flowers perfect in colour and form. Many of the older varieties do not compare at all favourably with those raised within the last ten years. In colour, lasting properties and, above all, productiveness they are far behind the newer kinds. Take, for example, White Pearl. This is now quite the finest white in cultivation, and is a great improvement on other white carnations. It is not a profitable concern to continue with the same stock year after year. Stock deteriorates, and for an equal amount of labour carnations superior in quality and number can be produced if new stock is periodically obtained. It is always interesting to try new varieties, and in these notes some of the best recent introductions are mentioned.

An excellent crimson with a delightful old clove scent is Sir Philip Sassoon. The flowers are borne on stiff, erect stems and the growth is compact. Lady Hindlip is a pretty carnation which has received an award of merit. The white ground of this variety is shaded and streaked with red. Mauve Queen is quite a break in colour, being a mauve pink, but on the whole it is not a particularly good variety. Shot Silk has been much talked of recently. It is described by the raisers as an Indian chestnut, flaked and rayed deep salmon red—an unusual colour. The flowers are very good in form and the calyx is non-splitting. Butterfly surpasses the last four mentioned in perfume. This is a white carnation delicately shaded with deep red.

Cameron and Beauty of Durham are somewhat similar in colour. Cameron is a bright rosy pink, and Beauty of Durham a brilliant salmon pink. Both are vigorous in growth and good in form. A really vivid and glowing cerise is Master Michael Stoop. The flowers are large, well shaped and the calyx does not split. It is a very effective variety. Another new cerise carnation is Janet, which is of dwarf habit and has flowers of a medium size. Red Laddie is a sport from Laddie. The red petals are shaded white towards the centre of the flower, which is borne on an exceptionally long, wiry stem. Dainty is an interesting novelty. It is an orange carnation with the groundwork heavily speckled salmon pink.

The perpetual border carnation is increasing in popularity owing to its freedom of flowering. A number of new varieties have been introduced recently, and among them are Sussex Tricolour, Sussex Flake and Sussex Ray. Sussex Tricolour has a white ground definitely striped and edged with mauve and cerise. Sussex Flake is a soft pink flaked with red. This is a strong, free-flowering variety. The striped crimson ground of Sussex Ray is attractive.

A border carnation which has a strong constitution is hardy enough to stand outside all the winter, and if it keep its foliage clean, is always sought after. It is interesting to experiment with new varieties to see if they possess those qualities. Caliban is a novelty for 1925. It is a striking fancy, the apricot ground is heavily marked with mauve and bright rose, and the flowers are of medium size. Dr. Stone is another apricot fancy with vivid pinkish red markings. Both of these are very robust. Joan Wardale is a crimson self which gained a first-class certificate last year, and John Stobart is a white and rose fancy of distinct colouring.

Several new varieties have been added to the famous collection of Douglas Cloves. Among them are Bookham Orange, Sultan and Coral Clove, all good border carnations. Bookham Orange is a vivid orange with large flowers of excellent form. Sultan is a dull orange-apricot variety, while Coral Clove has beautiful coral pink flowers borne on stiff stems 12ins. in length. These clove carnations are especially valuable in the garden on account of their sweet fragrance.

Some new Allwoodii have been added to the list, and are worthy additions to any collection. Three of the best are Roger, a salmon pink edged and rayed maroon; Jane, a light pinkish mauve with a deep red eye; and Anne, a white with a maroon eye. Both Jane and Anne are double Allwoodii with smooth-edged petals, and are sweetly scented.

THE GREAT CHELSEA SHOW

May 19th to 23rd

CHELSEA is so well known as the premier horticultural show of the world that it requires no introduction to our readers. Such is its importance that people come to see it from all over the world. This year the Council of the Royal Horticultural Society have started an innovation by making the Show last five days instead of the customary three. Whether this move is entirely wise remains to be seen. Certainly, as the Show is open until Saturday, it will allow many people to see it who are unable to spare the time on a weekday, but a five-day show creates difficulties for many exhibitors, particularly for those showing plants whose period of blooming is short or which are unable to stand the stuffy atmosphere of a hot tent for five days.

The freshness of the exhibits towards the end will depend more than in past years on the weather. It appears, at the time this note is written, as if the weather is going to be kind to us at Chelsea. There is general need of a month or two of dry weather, but, unfortunately, this sudden spurt of sunshine has appeared a little too late to be of much use to exhibitors; the season has been very backward generally, but it is amazing how plants have progressed considering the soaking they received last year.

As usual, the exhibitors have staged a noble show of blooms, which each year proves more and more that we have the best gardens in the world. Nowhere can be seen such a wonderful mixture of everything that is common and uncommon in horticulture.

FORMAL GARDENS

The gardens constructed at Chelsea this year are varied in design. Some are sunk gardens, others are bounded by low walls or trellis, while several have small streams running through them, which in their setting of vivid colours look most effective. Several of the gardens, with their rocks, stream and method of planting are more allied to semi-wild gardening than formal. In a few cases the plants were overcrowded and unsuitably chosen, but on the whole the gardens were good. Tall herbaceous plants on raised beds surrounding a formal sunk garden are not in keeping, and overcrowding is a great mistake. One or two of the gardens would be found impracticable.

A glimpse through one of the two entrances of Messrs. Carters and Co's. exhibit reveals a charming sight. There is a feeling of tranquillity and harmony in this garden of rhododendrons. The large circular garden is surrounded by conifers, the dark foliage of which makes an excellent background. Varieties of rhododendrons in many shades of red and pink have been selected, and are shown to perfection in the semi-circular raised beds, which at the back form a terrace. The low retaining walls are planted with aubrietia. In the centre of the garden is a round pool, upon which dark shadows are thrown from the neighbouring trees. The beds near the pool are filled with pink and red stocks, and a contrasting colour is introduced in vases by the planting of blue hydrangeas. The garden ornaments, too, are well chosen, and the stone seats, lead vases and two statues lend dignity to the scene.

The merit of Messrs. Cheal and Sons garden is that it is natural. It is not a blaze of colour produced by packing in tightly pot after pot of forced plants, as is the case with some exhibits. Under natural conditions these plants could not bloom so freely in such close quarters and this exhibit gives a true representation of the correct planting for this type of garden. The stream wanders slowly through the garden, and the gently sloping grassy banks are edged with moisture-loving plants. Groups of vivid azaleas, such as J. C. Van Thol, laburnums, acers and a hedge of conifers are seen round the outskirts. At the water's edge bold clumps of trollius, funkia, trillium and the large-leaved gunnera flourish in the cool rooting medium.

MESSRS. CHEAL'S WATERSIDE GARDEN.

THE SEMI-WILD GARDEN SHOWN BY MESSRS. WALLACE.

Digitized by Google

One of the best of the gardens has been constructed by Messrs. Wallace and Co. It should, perhaps, have been simpler and less crowded, but the general effect is good. Alpines of many kinds are growing in the steep rockery which rises up from the two pools. A winding path passes masses of azaleas and wistarias, which gives, when the summer-house is not in view, a Japanese effect to the garden. Rhododendrons, acers and conifers form a perfect setting.

Messrs. Gaze and Co. also have a stream and a summer house in their garden. Situated at the corner of two of the avenues, this firm have a first rate position for their exhibit and they have certainly made the most of it. In the space allotted to them they have constructed a rectangular garden with a high bank at the back, at the top of which the summer house is placed. This bank is a vivid mass of colour. Oranges, purples and mauves make a striking contrast against the young, soft green leaves of the shrubs or the dark crimson foliage of the acers. A small stream, planted on each bank, runs through the garden. On one side of the

A PORTION OF MESSRS. BAKER'S GARDEN.

exhibit is a quaint little sunk garden, which in itself is pretty, but is not in keeping with the rest of the garden.

A garden which, as it stands, would be an eminently suitable design for a town garden, has been constructed by Messrs. Vernon Bros. It is complete in itself and with its brown, square trellis work for covering the ugly brick walls of a London garden, its lily tank, wall fountain and paved walks, it is a garden of beauty and varied interest. The centre of the garden is slightly sunk, so that each end forms low terraces. Tulips, standard fuchsias, heliotropes, myosotis and azaleas, form the chief colour in the garden; while saxifrages, aubrietia, arabis, and many other plants flourish in the crevices of the stonework.

Messrs. Bakers have a delightful garden in which both the design and planting are good. In one corner, beside a heather-thatched summer-house, a small waterfall trickles down the ledges of water-worn limestone. Gradually this water forms a small stream, which winds through the garden past boulders of rock and under a stone bridge. Alpines of all kinds bloom happily in the rock crevices, and primulas and gentians flourish exceedingly. A large patch of Primula secundiflora is most effective by the waterside. Acers, daphnes, spiræas and many other plants form distinct groups of colour. The summer-house (which, in the opinion of some people, is not an attractive addition) is the best position from which to view this garden.

The small rectangular formal garden bounded on the four sides by low walls has been constructed by Messrs. Maxwell and Beale. The walls rather spoil this garden. Two paths cross in the centre, and at their junction an attractive old Somerset well has been placed. The well-head is thatched.

Most effective is the anemone garden of Messrs. Reamsbottom, who have arranged the beds in such a way that their famous St. Brigid anemones are well displayed. Each colour is separated into a different bed, and against the grey of the paths and garden ornaments the bright colours give a delightful effect.

Mr. John Klinkert has a formal garden composed entirely of clipped trees in many odd shapes and designs. Mr. Klinkert excels at topiary work, and this exhibit well maintains his high standard.

The effectiveness and utility of stone ornaments, seats, vases, balustrades, sundials and even dove-cotes was well shown by the formal garden arranged by the Horsecombe Quarries and Stone Works. They have constructed a rectangular garden, and circular stone steps lead down to a sunken middle portion in which a tall stone dove-cote has been placed.

The garden exhibited by Mr. Reginald Winder is good in design, but the colouring of the flowers is too pale to be effective. The colour scheme is white, pink and mauve; had the last two shades been of a deeper tint the garden would have been much improved. The insipidity of the flowers is due, to a large extent, to the fading in the sun of the forced blooms, but grown outside the varieties selected would be much brighter. The dwarf polyantha rose Ellen Poulsen, for instance, has turned to the palest of pinks. The steps on each side of the garden lead down to a small round pool. Clipped box trees stand on either side of the steps, and the surrounding beds are filled with dwarf polyantha roses in pink and white, and an edging of mauve violas finishes the bedding. Standard White Dorothy roses are in several of the beds, and clusters of pink ramblers cover the summer-house.

Berberis and crimson-leaved acers occupy the four oval beds in the garden, and armerias and saxifrages are placed in the cracks of the sandstone walls. The double-flowered gorse in the bed just outside and on the top of the walls forms a line of bright colour, but is not suitable for a formal garden.

Messrs. Ernest Dixon and Co. have a small sunk octagonal garden which is quite pretty but in no way outstanding. The steps and shape of the surrounding raised beds are good, but the planting might have been better arranged.

The brightest of any of the gardens is that of Messrs. R. and C. Cuthbert, which is formed only of azaleas. All the best and most effective varieties have been chosen, but unfortunately when the flowering period is over all the colour of such a garden would have gone.

The paving in the garden of the Johnstone Garden Contractors, Limited, is, perhaps, the best in any exhibit. Their garden is edged with yews and planted with hydrangeas.

Behind a fine exhibit of garden furniture by Messrs. W. Wood and Sons is a small formal garden constructed by this firm. The design is good and the garden gives a feeling of restfulness. Acacias, rhododendrons and azaleas brighten the small beds, and a comfortable summer-house adds to the appearance of the garden.

ROCK GARDENS

Nearly all the outside rock gardens are competing for the *Daily Graphic* Cup, and offer varying treatments of the classical theme of rivulet with waterfall, bordered by grey boulders set in turf. This has become almost a set subject for the competition, and year by year it becomes more pictorial and more remote from practical gardening, which is a little disappointing for the garden owner who comes in search of new ideas. It is a pity that the judges should set, or appear to set, so high a value on scenic effect to the neglect of sound and permanent planting, for they call the tune and the competitors must tread the measure.

This year the gardens are more brilliant and pictorial than ever, though more competitors than usual have abandoned the classic theme and struck out a quiet line for themselves. Apart from those few, the pictorial effect is more impressionistic than last year, and something of the prevailing fashion for violent colours, sharp-edged and unblended, appears in the colour schemes.

The lateness of the season and the earliness of the Show have tended to limit the choice of plants in flower, so that there are more anomalies of planting than usual, and in several gardens aubrietia and fancy violas have been turned into scree plants, and lime-haters and lime-lovers been compelled to forget their differences for a week.

It is interesting to see the individuality that different craftsmen have infused into the classical theme. Messrs. Brook have reproduced a Westmorland glen, with a perfectly naturalistic waterfall, dividing into two streams which unite to form a brisk little rivulet. On one side of the glen the strata have been broken by a fault which time has converted into a turf slide in which a dwarf spruce has found a lodging. Over this landscape a jewel box of glittering colour has been poised, so that the effect close up is kaleidoscopic and opalescent at a distance. The same firm have built to one side of the rock garden a little formal garden surrounded by a low wall of mossy stones enclosing a bed of old-fashioned flowers and a fountain spurting out of an old weathered boulder which is in itself a picture worthy of a fine frame. The effect is of a very old garden coloured and softened by the tone of time.

Messrs. Hodson have poured their colour in streams down wide, flat slopes of scree between grey boulders, and they have obtained it by the use of real scree plants—Androsace primuloides, Silene acaulis, Helichrysum bellidifolium, etc., soft pink and white and grey. Beyond their waterfall, almost hidden in a mass of ferns, is an apricot-coloured azalea that carries the eye back into the shrubbery and gives the impression of a garden that is continuous with its surroundings. Good use is made of dwarf conifers

Digitized by Google

to form a sombre little pine wood on one side of the glen.

Mr. G. Whitelegg's waterfall issues from a group of dwarf conifers weeping over a clump of pale lavender Phlox Laphami. On either side of the stream the colour is laid on in broad mosaics of magenta pink, chrome yellow and ultramarine. On one side of the garden, and round the corner, is a turfy hillside planted with buttercups and that fine old cottage-garden plant, the double lady's smock. Opposite to it is a conflagration of red and orange azaleas.

Messrs. Pulham have aimed at a much quieter effect with drifts of soft colours. A patch of dull red mossy saxifrage with white iberis and an old gold cheiranthus is alongside the delicate lilac pink of Æthionema Warley Hybrid. In the middle of the garden is a large grey boulder covered with silver saxifrage and a-wave with their white plumes, the silver and white and grey faintly lit up by few pink sprays.

Messrs. Cutbush have taken a very strong line with the classic theme, and their treatment of it is almost futuristic, a most interesting and unexpected development. Instead of the rounded, weather-worn boulders, their stone is sharp-edged and angular, built up into almost regular terraces which enclose masses of magenta azalea, golden Tulipa persica and grey-green Allium karatawiense. The waterfall is reduced to a trickle among ferns and the mountain path is represented by the sharp angles of a crazy pavement. As a sudden concession a group of Lewisia cotyledon (exceptionally well grown and floriferous) harmonises in its tea-rose colouring with the warm red of the sandstone. A rare plant is Lewisia columbianum that contrives to look like a large, strangely pink silver saxifrage and is given the real thing as a neighbour.

Messrs. Clarence Elliott have no waterfall and make no attempt to follow the convention, but have a cliff set with curious and interesting colours. The dull magenta and grey of Primula pulverulenta with the soft orange of a geum, the sulphur yellow of Primula sikkimensis with the delicate lavender of Cardamine pratensis fl. pl., and a drift of Rhododendron fastigiatum and alyssum, gold and pale violet. In front of the cliff is a conical mountain covered with the little spires of Juniperus compressus nanus, which are carpeted with Veronica repens and Silene acaulis saxatilis (a really free-flowering variety). The lower slopes of the mountain are planted with Mertensia echioides and Aquilegia flabellata.

Messrs. Gavin Jones and Ingwersen have taken a line of their own and reproduced a miniature mountain pass with a steep slope on one side and a rounded shoulder on the other. The shoulder is converted into a *pré fleuri* by close planting with small brilliant alpines, Gentiana verna, Trifolium uniflorum, Lychnis Lagascæ (a very pure pale pink), Linaria æquitriloba, a small form of Linum arboreum (soft butter yellow) and Aquilegia Helenæ in violet and white. The whole makes an iridiscent blending of cool colours. The steep slope is planted with larger and bolder plants: the moonlight broom, Onosma albo-roseum and Saxifraga Cotyledon caterhamensis with its great waving plumes of pink and white.

The miniature rock gardens under cover are little pictures of concentrated brilliance in which the exhibitors have contrived, with remarkable ingenuity, to suggest the qualities and possibilities that their plants would develop in a larger sphere, and at the same time they have created this year some exquisite little works of art.

Messrs. Frederick Wood of Ashtead have built up a background of subtly varying tones of green, dull gold and bronze, with dwarf conifers and Japanese maples, broken in two places by the cool colours of the smaller

THE FORMAL LOW-WALLED GARDEN OF MESSRS. BROOK.

MESSRS. JONES AND INGWERSEN'S BOULDER GARDEN INSIDE THE TENT.

A PORTION OF MESSRS. WOOD'S ATTRACTIVE EXHIBIT.

Digitized by Google

brooms, pale sulphur yellow, ivory white and the curious subdued rosy purple of Cytisus Dallimorei. In the middle of the exhibit is a miniature pond overhung with brownish orange mimulus and sprays of white Saxifraga Cotyledon, and bordered with mossy phloxes and the delicate lilac blue of Campanula Steveni. Verbena chamædrioides, which seems to be hardier than is generally supposed, is shown growing through a prostrate juniper, a situation that apparently suits its needs as well as it shows off the glowing orange scarlet of its flowers.

Messrs. Gavin Jones and Ingwersen have built up a rounded boulder at one end of their exhibit with masses of greyish purple saxifrage infiltrating its crevices and surrounding a wide mat of the greenish silver Raoulia australis, the whole forming a subtle harmony of colour with a restful feeling of permanence; at the other end a bold mass of golden Tulipa persica is grouped at the feet of the three tall conifers.

Messrs. W. H. Rogers and Sons have a large double-sided exhibit containing a blaze of Welsh poppies bringing out the value of the double orange form, which never looks so well alone as when associated with the singles, whose colour it seems to enhance.

Clarence Elliott and Co. have piled up a cliff, planted with rock rhododendrons and Daphne petræa, overhung by pink clouds of Saxifraga Cotyledon, with at one side a juniper hill rising austerely out of a brilliant alpine lawn. A "pretty conceit," as Parkinson might have said, is a single specimen of a minute, very deep pink form of Primula farinosa set like a jewel in the middle of a round silver plaque of Raoulia australis.

Messrs. G. H. Crow show how many colours the rock garden can produce by massing together every imaginable shade, from the black of Bowles' viola to the crushed strawberry of Malvastrum Monroanum, into a glittering tapestry.

Messrs. Waterer group lady's slipper orchids, in rose and white and golden brown under copper-coloured Japanese maples, and surround them with a carpet of violet wahlenbergias, mossy phloxes and pale pink daphne.

Messrs. Tucker of Oxford carry up their garden higher than most with tall spires of delphiniums and white lilies. Alongside them the moonlight broom comes spraying through the dark branches of a dwarf spruce.

TREES AND SHRUBS

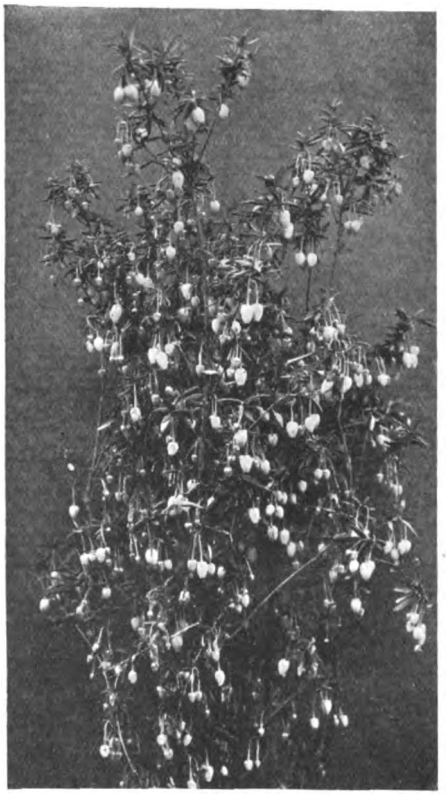
Shrubs are as well represented as ever. Luckily, this fine spell of warm weather has brought on plants which would otherwise be unrepresented. The grouping on these stands is a noticeable feature which seems to improve yearly.

Messrs. Waterer, Sons and Crisp are again staging their fine rhododendrons and azaleas. Among them is the sport from Pink Pearl called Mother of Pearl. There is, no doubt, a great future for this fine rhododendron. The truss is about the same as that of Pink Pearl, but the texture is a little firmer, while the colour is a beautiful white, which is set off by the rose-coloured stamens. Another good hybrid is Starfish, a good pink with darker rose-coloured buds. The petals are reflexed and the truss looks straight at one. We are glad also to see a fine show of Azalea Kæmpferi on this stand. This azalea, with its terra-cotta flowers, is perfectly hardy and should be far more grown than it is at present.

Messrs. Koster and Sons are staging a fine exhibit of their famous hardy hybrids. Among the most noticeable are Mrs. Lindsay Smith, a particularly pure white, faintly tinged with yellowish green at the throat and with a few greenish spots on the upper petal. Miss Noreen Beamish is a clear rose without markings, while Rosamund Millais is a good carmine with very dark leopard markings on the upper petals.

Messrs. Cuthbert are showing a large exhibit, in the main tent, of their hardy azaleas. This includes nearly every class and proves the worth of these most useful plants. Mollis Comte de Gomer is a fine salmon orange of nice free habit, while one is glad to see the fine Azalea Daviesii with its pontica blood in it. The smallish flowers are carried in good trusses and are white tinged with yellow on the upper petals.

The Executors of the late Mr. Anthony Waterer have a large stand of his famous strains of hardy hybrid rhododendrons. With the exception of two all of the plants shown were raised at Knaphill. Such old favourites as B. de Bruin, still one of the finest of crimson hybrids; Sappho, a fine upstanding conical truss of white flowers with a deep purple blotch on the upper petals, and so on. This strain is famous for its absolute hardiness and, although



THE MAGNIFICENT CRINODENDRON HOOKERI, SHOWN BY MR. REUTHE.

some of the newer hybrids have larger flowers, yet few can vie with these old favourites in free flowering year after year.

Messrs. L. J. Endtz of Boskoop are showing a few hybrid rhododendrons and some fine azaleas. Among them is a magnificent new Mollis × sinensis called Alma Dyke. The colour is terra-cotta orange. Another good terra-cotta colour is that of Baheuf, another mollis × sinensis seedling. This firm is wholesale, and does not cater for the retail trade.

Messrs. Cheals are showing a fine exhibit of ornamental and flowering trees and shrubs. The main theme is Acer palmatum var. atropurpureum and laburnums. These are two plants particularly useful for grouping together, as the fine dark leaves of the acer show off the yellow of the laburnums exceedingly well. Lilacs, rhododendrons, azaleas and cytisus are also prominent.

Mr. Reuthe's exhibit is most noticeable for three very fine plants of Crinodendron Hookeri. These are so fine that they stand out among all the fine plants at Chelsea. The pendent scarlet drupes are thick on a shapely bush about 7ft. in height. Unfortunately, this plant is scarcely hardy. Other plants on Mr. Reuthe's stand are azaleas, Kalmia latifolia, brooms, enkianthus and numerous rhododendrons, among them Lindleyanum, Keysii and campylocarpum.

The Donard Nursery Company are exhibiting ornamental and flowering trees and shrubs. Among them are fine plants of Ilex Pernyii, I. Fargesii, a very handsome evergreen with narrow leaves about 4ins. long which might be more often seen; and Lomatia pinnatifolia, a fairly hardy evergreen with leaves cut like a fern.

Mr. Lewis of Hanwell is staging standard and bush hybrid rhododendrons in a good and well grown assortment.

Mr. Notcutt is again showing his well known standard cytisus, including Donard Seedling, Daisy Hill splendens, Osbornii, along with various maples, lilacs and weigelas.

Along with lilies and irises, Messrs. Wallace are showing many well grown hybrid rhododendrons, such as White Pearl, Ascot Brilliant, N. N. Sherwood and Armistice Day. All the hybrids on this stand are perfectly hardy and will stand full sun.

Messrs. Hillier are staging a fine exhibit of shrubs. It is pleasant to see Viburnum macrocephalum, one of the finest of all the sterile viburnums and invaluable for an inside wall in a cold house. The main exhibit consists of hydrangeas of various forms, cytisus and wistaria, with a sprinkling of retarded prunus and pyrus, among them Pyrus Malus Sargentii. A number of rare shrubs are to be seen on this stand, such as Daphne caucasica, an old introduction but now rare in cultivation, Fothergilla major and Prunus Padus grandiflorus.

Mr. Slocock has a good exhibit of hardy hybrids, among them the rhododendron and azalea cross of creamy yellow called Broughtoni aureum, Goldsworth Crimson (a fine upstanding hybrid) and some new Aucklandii and decorum seedlings are also shown.

The Yokohama Nurseries staged their usual exhibit of trained and dwarfed trees together with azaleas.

Messrs. Robert Green, outside the tents, are exhibiting their collection of trained bays. For all who want hardy trained trees, these are admirable, whether in plain clipping or those with spiral stems.

Messrs. Charlton are staging a large exhibit of hardy shrubs. This firm specialises in various forms of maples, and their specimens, whether cut-leaved, variegated or coloured, are all well grown. They also show Lavender Stœchas, a curious plant with flowers in rows forming a quadrilateral, and large violet bracts coming out at the top. It comes from the Mediterranean and is not over-hardy

In addition to their other exhibits, Messrs. Cutbush have a most excellent collection of clipped boxes and yews. Whether in plain shapes or in birds and animals, they show good cultivation, while the clipped box fence is both novel and attractive.

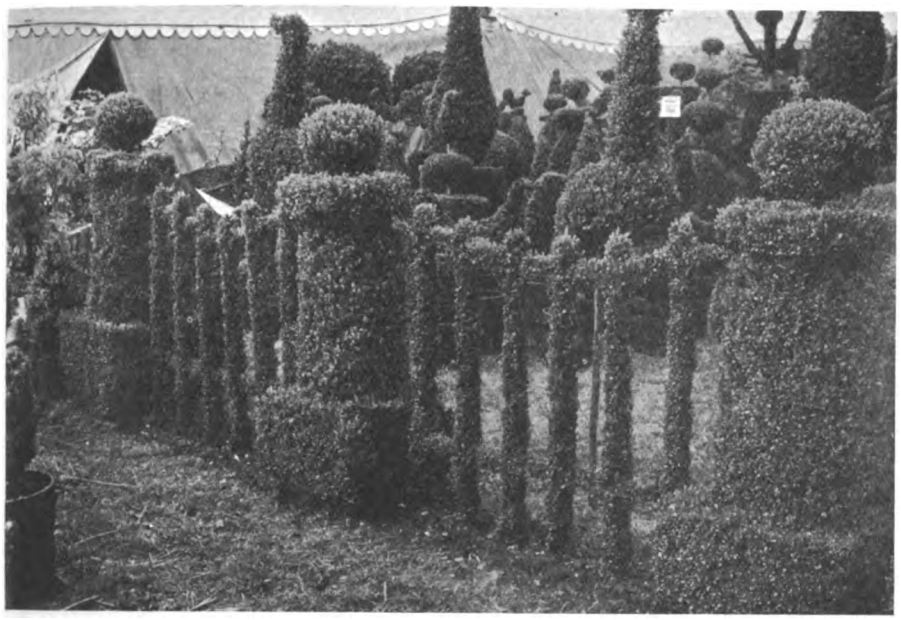
Messrs. Fromow's collection of maples requires no introduction. Their variety in shape and form and colour of leaf is endless.

Mr. G. Whitelegg, along with his alpines, stages azaleas and broom.

Mr. Charles Turner shows white greenhouse rhododendrons, such as Purity, Exoniensis and Beadonii, obviously with Nuttallii blood in it, owing to its long trumpet. On another stand he is staging lilacs, which are not so far advanced this year as last. Among the best are Charles Joly, a beautiful semi-double of deep claret colour; and Princess Marie, also a semi-double rose-lilac of a good shade.

Messrs. Watsons of Dublin are showing a fine new seedling broom called Dorothy Walpole. The colour is pure, but difficult to describe. It might be called dull crimson.

Digitized by Google



A CLIPPED BOX FENCE SHOWN BY MESSRS. CUTBUSH.

Messrs. Russell have an outside exhibit of hardy and semi-hardy shrubs, such as maples, pittosporums and olearias. They also show a number of ornamental vines, including those fine species, Vitis Henryana and V. heterophylla.

Messrs. Gill stage a number of tender and hardy rhododendrons. Their form of R. Falconeri is particularly fine, with a larger truss than is usually seen. Among others are Dalhousiæ, Cornish Cross and Beauty of Littleworth, one of the best white hybrids in existence.

Messrs. Harrods are exhibiting a collection of clipped trees for formal work.

LILIES

As was the case last year, Messrs. Wallace of Tunbridge Wells are almost the only firm exhibiting these flowers. The oval group in the centre of their exhibit comprises Lilium longiflorum var. formosum, whose large and beautiful white blossoms override the dwarfer varieties of the umbellatum and Thunbergii sections. L. Brownii, with its handsome blooms so characteristically streaked with brown on the back of the segments, and L. regale, which truly deserves its specific name, with its nodding flowers tinged with gold in the throat and the bright yellow anther heads, call both for attention and admiration. L. regale undoubtedly is one of the lilies of the immediate future. The tall and handsome L. excelsum is also present, set off to advantage by a dark background of cupressus. A patch of brighter colour is supplied by the judicious placing of plants of L. umbellatum splendidum; while Orange Queen, of the Thunbergii section, supplies a lighter tone. A variety of which there are only a few plants is Golden Fleece, belonging to the umbellatum series, and it is worthy of attention. L. Martagon dalmaticum is as beautiful as ever, both in the unopened and full out conditions, with its reflexed flowers of a pinkish tinge. One of the most interesting species in the group is L. Farreri, whose elegant and pendent white blossoms are so quaintly marked with spots of a bluey mauve tone. A no less beautiful and decorative half-hardy species is L. Krammeri, so called after its discoverer. Like L. longiflorum, it carries large flowers, the perianth segments of which are of a delicate shade of pink overlying white. Unfortunately, unless given a very sheltered spot it does not thrive outside. Another graceful species which cannot fail to be admired is L. Willmottiæ.

A few plants of L. longiflorum var. formosum are staged by Messrs. John Peed and Son in their exhibit of greenhouse subjects. These are well grown and carry many large shapely blooms of pure white with the slight tinge of green in the throat so characteristic of this species.

Messrs. Bunyard of Maidstone also stage a few groups of L. longiflorum var. formosum and L. regale, which give a pleasant contrast with the blues of the irises, the main feature in their stand.

CLEMATIS

As in the past, Messrs. George Jackman and Son provide one of the most interesting but by no means less beautiful features of the Show by their excellent exhibit of all the leading varieties of large-flowered clematis in commerce. Every year this firm seem to do better and better, and this year they fully come up to the high standard they set last year, if they do not surpass it. Blues, mauves in light and dark shades, delicate pinks, along with whites, all mingle together and produce an effect that is rarely obtained by any other flower. These shades are brought out in relief by the foliage of a few of the brilliantly autumn-tinted Japanese maples at well chosen points. When coming to single out varieties it seems invidious to mention names, as one is equally as good as its neighbour. We must, however, submit a number which appeals to us. In the singles, such varieties as Lady Londesborough, with large blossoms of a pale mauve colour; Alexandra, with fine spreading flowers made up of four petals of a delicate mauve with a ring of white stamens in the centre; Jackmanni superba, a much improved form of the type carrying beautiful dark purple and velvety blooms; Mme. Edward Andre, with flowers of a good red tone; King of the Belgians, lilac-blue with a tinge of pink; W. E. Gladstone, with large blooms made up of spreading spoon-shaped petals of a light blue colour; and last but by no means least, The Bride—one of the new varieties, which, in addition to being tall and handsome, is probably the freest flowering white variety we have. In the double forms, we note the ever popular Belle of Woking and Duchess of Edinburgh (white).

In their exhibit of greenhouse plants, Messrs. L. R. Russell of Richmond stage a few of the more popular kinds, and these lend a distinct touch of colour against the foliage of the other shrubs on their stand.

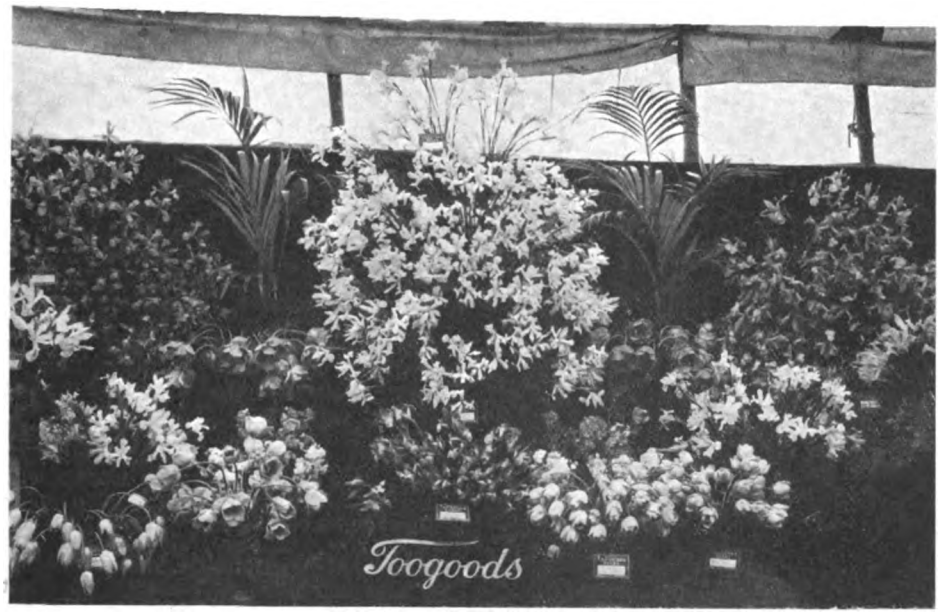
IRISES

Both alone and associated with other flowers irises are to be seen in all their glory. The tall pallida irises predominate, and these are represented by many excellent varieties which have long stems bearing two and three and at times even more flowers fully open.

One of the largest collections is that of Messrs. George Bunyard and Co., who are to be congratulated on the success of their arrangement. There are irises of all possible types and colouring, and to break the lines and show up the charm of form which is peculiar to the iris they have occasional patches of Lilium regale and Campanula Fleur de Neige. The white flowers of these two plants are an immense help to the scheme. Except perhaps for the yellow-tipped white flowers of Iris Monieri, white does not naturally enter into the iris

A PORTION OF MESSRS. BUNYARD'S FINE COLLECTION OF IRISES.

Digitized by Google



SOME OF MESSRS. TOOGOOD'S SPANISH IRISES.

scheme. Perhaps the very best of their many pallida varieties are Alcazar, Mme. Schwartz of delightful lavender tone, Corrida, Crusader (a medium blue flower brightened by a gold crest), Asia (which has a metallic lavender standard and deeper coloured falls) and Prospero. The squalens section, of lovely but baffling colour schemes, are represented by many most desirable varieties. A good selection of those to be seen includes Ambassadeur, Rosalba, Her Majesty and Glamour of pink tones, and Princess Victoria Louise, which has deep primrose yellow standards.

These lovely May and June flowering irises are also used to good effect by Messrs. Wallace and Co., who are showing a great many splendid sorts arranged in beds around their central stand. Here, again, it is the Iris pallida varieties that attract first attention by reason of their greater height and the depth of the falls on the plentiful flowers. Magnifica, of rosy lavender and rich purple colours, is an excellent example of this type. Tamerlane has pale blush standard and dark blue falls, Souvenir de Mme. Gaudichau, Shalimar, Mme. Schwartz with soft blue standards and deeper falls, Asia, Alcazar, metallic lavender standards andr ich purple falls, Lord of June with the palest lavender standard and silvery blue falls, Amy Page of Cambridge blue colouring. Queen of May (rose pink and yellow), Fro (rich yellow standards and rosy maroon falls) are splendid squalens varieties. Rather dwarfer, but of sturdy habit, are Blue Boy and Blue Bird, which are beautifully coloured. Interspersed with the above Messrs. Wallace and Co. have some of the beautifully marked oncocyclus irises, including Iris Susiana, I. Leichtlini and I. Psyche.

The grouping of the different varieties in the collection of Messrs. Barr and Sons is singularly effective, and this method well illustrates the garden value of the plants. The chief group is of Peter Barr, a tall iris of very pleasing lavender shades; Purple Laugier, of darker colouring, is an excellent companion variety, as also is La Beaute of rich blue shade. In the background may be seen grouped plants of Rhein Nixe bearing on graceful stems large flowers with white standards and rich purple falls, while near by is the rich blue Duchess of York. The blush pink shading of Wyndham is especially charming, and this harmonises well with Mme. Chereau, which is of creamy yellow colour broadly edged with pale lavender. Jamerlam is of striking metallic blue and purple colouring. Red Cloud, with its pink-toned standard and reddish mauve falls, also attracts attention, though none of the many varieties so well shown by Messrs. Barr and Sons is more beautiful than Quaker Lady, a rich flower of the I. squalens type.

The Orpington irises are set out on staging in the middle of the large tent, and here they may be closely inspected. In addition to many of the pallida section, they are showing some rarities, and among them is Cretan, which is especially noteworthy on account of its unusual height and the delightful fragrance of the flowers. This harmony in blue and maroon shades was found in Crete, from which it obtains its name. Tiflis and Caucasican are said to be seedlings from Iris imbricata. Although of dwarfer habit than the previous variety, they have large flowers of great charm. The former is of metallic blue shades, while yellow predominates in the latter. Scrimgar of very dark purple colouring possesses unusually long falls. Fritjof (blue), Royal (a very dark blue), Odin (white with yellow crest), Yellow Hammer and Zwanenberg are other delightful irises to be seen in this collection. A little bowl of I. californica seedlings is particularly charming and of especial interest in that a great variety of fascinating flowers may be raised from seed sown out of doors.

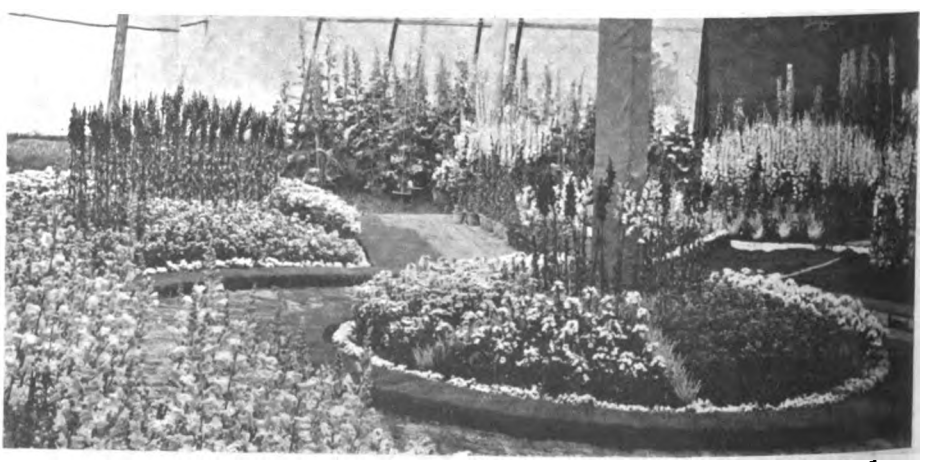
On Messrs. Toogood's stand a large collection of Spanish irises interspersed with Darwin and cottage tulips and sweet-scented stocks is shown. The irises are well arranged in tall stands, and include II. filifolia, Imperator (dark blue shades), Sensation (paler blue), Hart Nibbrig (medium blue), Innocence and Flora (pale shades).

In association with his unique collection of hardy ferns, Mr. Amos Perry finds an excellent setting for some choice irises. The Regelio-cyclus varieties, with their fascinating markings, are to be greatly admired. Typical examples are Cyclemestra, Olympia, Luna and Charon. The last named is, at first sight, weirdly sombre, but its full beauty increases with a closer inspection. I. Korolkowi has lovely lavender lines on a pale ground, while Sirona is of very uncommon reddish maroon colour. Besides the above, there were a goodly few of the taller pallida section and such as Bosnia maculata, with straw-coloured standards, and the blue shaded Mars.

De Golde are showing Dutch irises, tulips and anemones. Among the first noticeable varieties are Præcox, a good lavender, a fine golden yellow seedling, and David Blesh, a very good blue-lavender. This firm is wholesale only.

ANNUALS

A considerable amount of time and thought must have been expended by Messrs. Sutton and Sons on their unique exhibit. The general idea, as the military have it, is a central circle of antirrhinums and nemesias, with radiating blocks of the same plants in very many varieties. Broad gravelled paths, bordered by close grass of the greenest and most even texture, give easy access to the exhibit. Generally it is composed of antirrhinums and nemesias—there are a few other plants, a very dwarf white alyssum, the variegated coleus, but these are quite secondary to the scheme. Each individual of the immense number of plants is a model of the highest cultural skill. Many of the tall spikes of antirrhinums measure over a foot in length each, while the nemesias are studded with flowers. The principal antirrhinums are Old Rose, Buff-Pink and Bronze, of the tall varieties. Mauve Queen, Mauve Beauty, Buff Beauty, Cream, Deep Crimson and Rosy Queen, of the intermediate type. Excellent as are these stately antirrhinums, which first catch the eye, they are surpassed in the cultivator's esteem by the nemesias, whose flowers are exceptionally large and of great depth of colouring. Cherry Red is a brilliant variety, while Blue Gem is almost like a giant forget-me-not. Aurora and Twilight are the names of two uncommon bicolor varieties, the former has red and white flowers, while those of Twilight are mauve and white.



NEMESIAS AND TALL ANTIRRHINUMS COMPRISING MESSRS. SUTTON AND SONS' EXHIBIT

Digitized by Google

Generous banks of schizanthus and stellata cinerarias are the keynote of the very attractive exhibit arranged by Messrs. Webb and Sons. The cinerarias are especially delightful and these lead down to plants of the large-flowered type on the ground line. From the profusely flowered schizanthuses spring groups of gloxinias of a good strain, clarkias and Primula obconica.

At the far end of the large tent Messrs. Carter and Co. have a wealth of bloom on magnificently grown plants. There are large mounds of a double, rose coloured clarkia and stellata cinerarias, circles of monster hippeastrums of great merit, gloxinias of many sorts, and Schizanthus Carter's Butterfly. Through the whole length of this large exhibit there runs a most fascinating line of Carter's Queen of the Roses petunia. The gloxinias include such splendid strains as Carter's Spotted, Invincible Prize and Cyclops. Their long-spurred aquilegias and the two groups of Phlox Drummondii, pale salmon and crimson, are equally charming. This large group is bordered by lily of the valley, bearing countless numbers of fragrant flowers, and is flanked by other groups composed of Cinerarias Bouquet Pink, Bouquet Blue and Bouquet Mixed, Spanish irises, schizanthus, nemesias and antirrhinums.

In the orchid tent Messrs. Watkins and Simpson have a large group of schizanthus Dr. Badger's strain. These magnificent plants, in 10in. pots, bear enormous quantities of flowers in a fascinating variety and delightful colours. At each end of the oval group they have placed dwarf floriferous plants of their Salvia Harbinger, which well illustrates its earliness and great garden value.

Quite distinct in type and character is Mr. A. Dawkins' strain of dwarf hybrid schizanthus. These are wonderful little plants about 15ins. high and growing in 5in. pots. They are exceedingly floriferous and embrace every possible shade of colour. Schizanthus Wisetonensis varieties, with exceptionally large spikes of a white stock, probably Snowdrift, are shown by Messrs. Godfrey and Son, while the Blakeney Nurseries Company are showing schizanthus with Coltness Gem dahlias.

This break in dahlias, as typified in Coltness Gem, is a valuable one for all lovers of this fine genus, as the colour is very pure.

VIOLAS & PANSIES

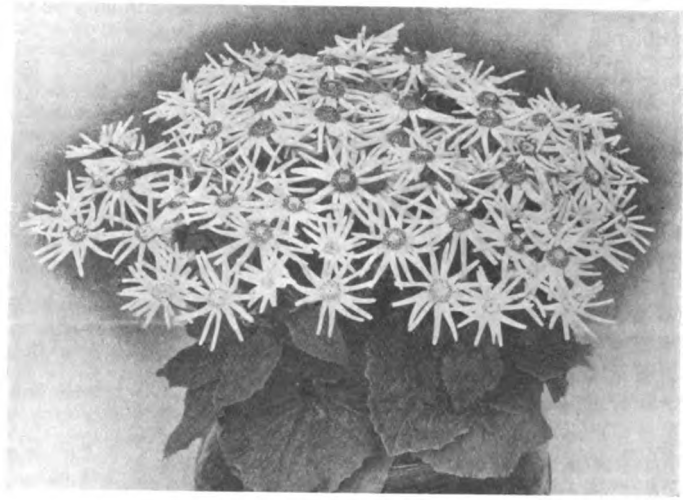
There are no pansies, but violas are represented by two excellent collections, arranged on tabling in the middle run of the large tent. Both collections include varieties with flowers as large and almost as rigidly formal as those of the show pansy, and also the relatively tiny gracilis, which is so free-flowering and of such graceful habit.

Of the large-flowered violas being shown by Mr. Wm. Yandell, one admires Malcolm Miller of primrose colour with heliotrope markings. Rebecca is a deeper yellow shade with similar edgings of heliotrope. Mrs. Milligan is the best white. Moseley Yellow has flowers of very rich colour. Mrs. Mac-Ewan is creamy yellow, edged with purple. Oxhill Purple is a richly coloured flower. Elsie Purser is a deeper and velvety purple. Mrs. Edith Bastock is purplish violet, with light rays. Springwell Bronze is the very best representative of the bronze violas which are always so popular that the supply never equals the demand.

Equally good violas are shown by Mr. H. Clark and his method also shows off the flower to the best advantage. Those especially to be noted include Admiration, dark blue; Archie Grant, deep indigo blue; Baron Newlands, deep yellow, edged blue; Blanche, a large creamy white; Donald McDonald, cream, broadly edged with azure blue; George Callan, crimson marbled with pink; Hunter Beattie, large rose self; Jean Paterson, white, streaked with violet; J. V. Macdonald, pure white; Maggie Mott, soft mauve; Miss A. Norton, large dark purple; Mrs. James Scalley, white edged with blue, and Mrs. Chichester, white marbled with blue.

In association with their well grown double marigolds, Messrs. Artindale and Son placed bowls of violas. The chief sorts were George Macdonald, yellow, lightly flaked with heliotrope; Mrs. Marriston, dark mahogany striped with rose, giving a suggestion of bronze; Mrs. Ben Waid, white, freely striped with deep mauve; and Bessie Ferguson, pale cream, definitely bordered with deep heliotrope.

With their zonal pelargoniums Messrs. Jarman and Co. showed baskets of Viola Purple Red, Mauve Queen, Heavenly Blue, Wyndly Gem, Dainty, reddish maroon with blue.



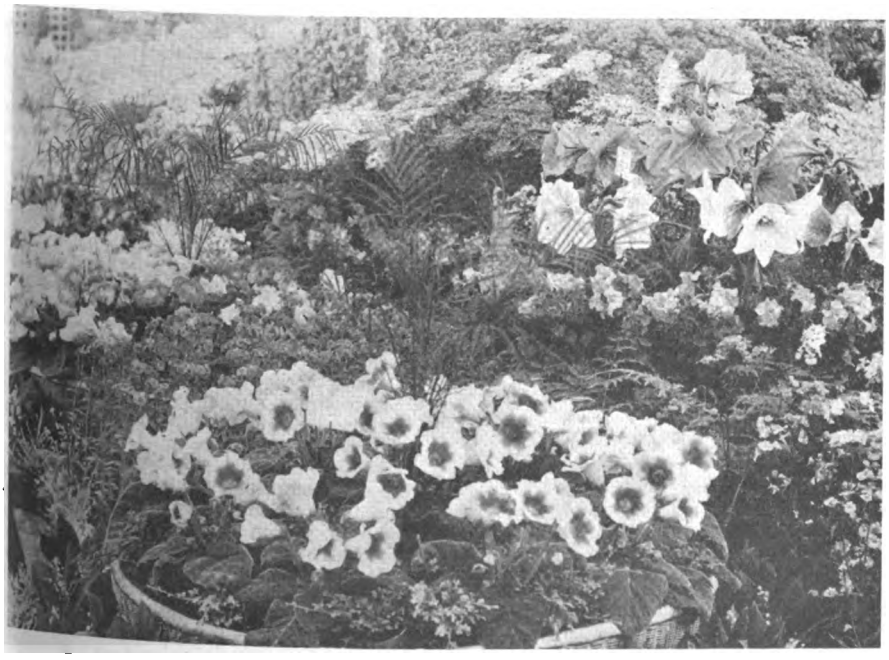
ONE OF MESSRS. WEBB'S NEW CINERARIAS.

CARNATIONS

The growing popularity of carnations is clearly evidenced by the magnificent exhibits put up by the leading raisers of this flower. They undoubtedly add a valuable contribution to this annual commonwealth of flowers, and, although surrounded by a host of many other equally beautiful subjects, yet they take a leading place, which is in no small measure due to their extensive range of colour, their large blooms, and in the varied uses to which they can be put in the garden. Year after year, novelties make their appearance, combined with the improvement of the older varieties, and the attention of the public cannot but be focussed on such floral assets to the garden.

This great advance is illustrated by the extensive collection so admirably staged by Messrs. Allwood Brothers in the large tent. This is probably one of the largest exhibits of carnations ever staged at Chelsea or at any other flower show. The style of the exhibit is unusual, but nevertheless attractive. The perpetual-flowering varieties are grouped in the centre of their exhibit to form a large coronet, and as such is most effective. This group contains a number of novelties, and of those we note Shot Silk, Indian Chestnut, flaked red; Cameron, rose pink; Butterfly, white overlaid claret; and Beauty of Durham, salmon pink. There are, in addition, several of the older and better known kinds, such as Jessie Allwood, which still ranks as one of the best yellows we have. Laddie, of a glorious shade of pink, is also there.

The border varieties, Allwoodii and the new perpetual border forms are set out in beds with grass edgings which enhance their general appearance, although, unfortunately, the fact that the flowers are in vases is only too evident. The most striking novelties are the new bizarre carnations, such as Sussex Flake (blush striped red), Sussex multi (red striped crimson and maroon),



A CORNER OF MESSRS. CARTER'S FINE EXHIBIT SHOWING THEIR GLOXINIAS.

Digitized by Google

Sussex Ray (flesh striped crimson-claret). These undoubtedly appeal to many, while others again are better contented with the Allwoodii, in which section they will find Ann, a large double white with a maroon eye; Jane, a large double pinkish mauve; and Roger, of a deep salmon tint rayed maroon. These three novelties show in some measure what a considerable advance has been made in this class. In the old-fashioned border section almost all the up-to-date varieties are on show in their myriad shades of pinks and crimsons.

Messrs. C. Engelmann, Limited, whose fame as growers and raisers of carnations is spreading rapidly, are also staging an enormous and magnificent group which comprises upwards of 10,000 blooms. The exhibit gains much in appearance from its corner situation, and this has been taken advantage of to the full in the general arrangement. The blooms are all exhibited in vases and look exceedingly well with trimmings of asparagus for decorative effect. In the corner stands a magnificent array of blooms of Enchantress Supreme, flanked on either side by the bright scarlet blooms of Tarzan; while Red Laddie, a 1925 novelty with flowers of a rose-cerise shade, comprises the foreground. The huge vases of Nigger also make their appeal and provide a patch of a darker shade which serves to throw up in contrast the beautiful blooms of White Enchantress and the blush pink flowers of Canada, a variety recently registered by this firm. Another variety, Dainty, with blooms of yellow flaked with crimson, also calls for a word of admiration.

Messrs. Keith Luxford are staging a fine collection on a table space in spray vases. Wonder. The green of the decorative foliage considerably enhances the appearance of the stand.

Alongside their collection of greenhouse plants, Messrs. Stuart Low and Co. are staging vases of White Pearl, with Topsy in the background providing good contrasting effects. A dainty touch is supplied by the use of hanging baskets filled with that charming salmon-pink variety, Eileen Low. These flank the other kinds. Sir Philip Sassoon is seen in larger quantities than was the case last year. It has the rich maroon shade and the old clove perfume of the old English clove A touch of lilac pink is supplied by Mauve Queen, while a dash of brighter colour is produced by a pretty fancy variety, Lady Hindlip, with white ground striped carmine.

Mr. James Douglas, whose name is almost synonymous with clove carnations, is exhibiting a large number of splendid blooms. Among the fragrant clove varieties which are on view are Bookham Flame, of a wonderful flame apricot shade; Wonder Clove, carrying huge blooms of brilliant scarlet; Salmon Clove, of a soft salmon shade; White Clove, snowy white; Queen of Cloves, of a delicate shade of lilac rose. The fact that all these clove varieties are hardy in any part of these islands is not, perhaps, so universally understood and appreciated as it ought to be, and their presence in the garden lends an old-time flavour, as well as adding considerably to the perfume of the other flowering subjects. Mr. Douglas also stages quite a number of border varieties, and these, considering the earliness and the general backwardness of the season, are in remarkably good condition.

THREE OF THE NEW SUSSEX FLAKED VARIETIES EXHIBITED BY MESSRS. ALLWOOD BROS.

The fact that the old varieties are still good and also popular is furnished by this exhibit, which contains all these old stagers. Surprise is quite a novelty, however, and is good. It carries large blooms of a fine delicate pink colour. Mikado is there and still holds the fort as regards a good mauve, while Aviator retains its position as one of the best scarlets. Mrs. Walter Hemus is a good pink, and Topsy a good crimson. Among whites, we single out Wivelsfield White and White

That amateurs can put up successful exhibits is evidenced by the one staged by the executors of the late Sir William Cain. The effect is so natural, owing to the grouping of the blooms. Pinks, whites and crimsons mingle together, and give the most pleasant effects. A large group of Souvenir de la Malmaison Princess of Wales calls for attention, although the individual blooms are rather past their best. White Pearl is there, also Carola, a good maroon crimson.

Mr. F. W. Seymour of Finchley stages excellent blooms in vases of such border varieties as Mary Murray, Lady Shackleton, Salmon Clove, Sir Douglas Haig and Steerforth. The whole exhibit, which is well arranged, reflects credit on the exhibitor.

Last, but by no means least, comes Messrs. Lowe and Gibson's table of carnations in pots. The arrangement aims at producing an effect as obtains in any garden. One variety which takes the eye is Joan Wardale, a novelty and a really good rich crimson self. It is rather early in the season to judge of its capabilities, but we should think it is one of the coming varieties. Mary Allwood is there, and is probably the best yellow self there is. The perfectly formed blooms are carried on long stems. A novelty for 1926, Mrs. L. Gibson, reminiscent of Kelso, is most attractive. It is a flaked variety, and is a much better grower than Kelso. Older varieties such as Elaine, Mrs. Nora Cox and Gordon Douglas, are still to the fore and are as yet hard to beat.

HARDY FLOWERS

In the big tent Perry's Hardy Plant Farms exhibit one of their usual splendid collections of hardy ferns, with a suitable and beautiful foreground of cut herbaceous flowers and growing alpines. Besides a considerable collection of fine, if backward, bearded irises, Camassia Leichtlinii var. lutescens, Dodecatheon Meadia and D. Purity, a beautiful, almost golden yellow Moræa species, Trollius Orange Prince and Watsonia Arderni, are specially noted.

Messrs. Storrie and Storrie of "Tiny Seedling" fame, have a circular group of really fine long-spurred aquilegias, polyanthus and alpine auriculas of the free and easy type, suitable for border decoration; altogether a very interesting and attractive exhibit.

On Mr. G. Reuthe's exhibit of varieties we note, among a great number of flowering shrub sprays, the capricious Chatham Island lily, Myosotidium nobile, and the remarkable Beschorneria yuccoides, a rare Mexican succulent, hardy in our more favoured localities.

Messrs. Bees have a well spaced group, containing a wide variety of herbaceous and alpine plants, diversified with brooms, lilacs and other shrubby things. A very beautiful fern, Struthiopteris pennsylvania, occupies a prominent place; lupins, long-spurred aquilegias, candelabra primulas and an exceptionally fine strain of polyanthus occupy considerable spaces, and we noted fine colonies of the rare Primula chrysopa and Incarvilleas brevipes and Bees' Pink, as well as a really considerable drift of the quaint and still rare Roscoea cautleoides.

Messrs. Geo. Bunyard and Sons, in their fine group of bearded irises, include two fat clumps of the double white Campanula persicifolia, known as Fleur de Neige. As a bellflower, this is a wash-out, but considered as a mass of pure colouring, with a spikey—rather viscaria-like—effect, it is worth noting for the early summer border.

Mr. E. Scaplehorn includes in an exhibit, mainly alpine in character, Verbascum densiflorum, the double white rocket and Tritoma aurantiaca.

Messrs. Artindale and Son have a gorgeous mass of colouring in a table group of a very fine form of our old friend the Scotch or pot marigold masquerading under the name of "Ball's Calendula!"

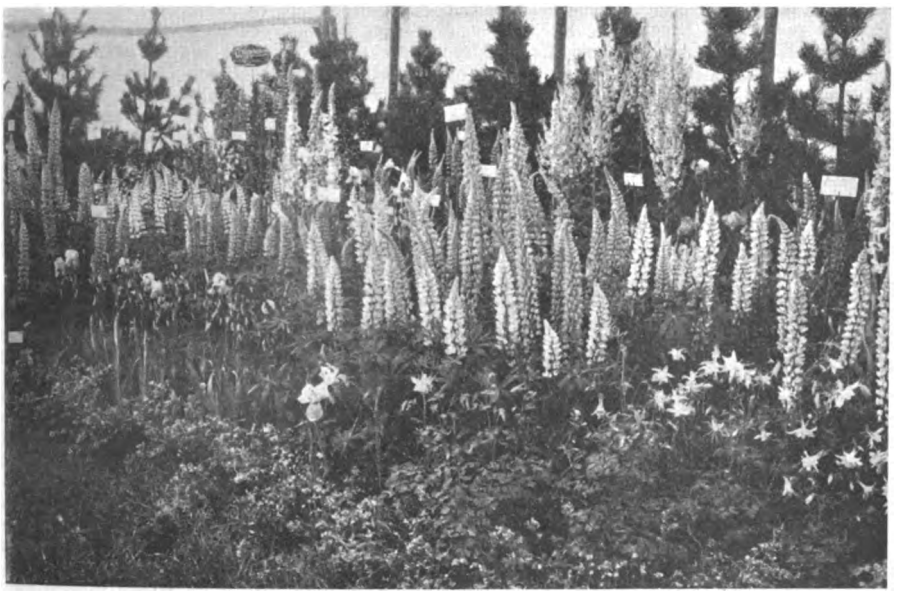
It is yet early in the season for the delphinium, a flower which does not take kindly to forcing, yet the bold group with which Messrs. Blackmore and Langdon flank their splendid begonias is built up of plants admirable in form, colouring and stature. An immense and perfect spike of the heliotrope

Digitized by Google

Mrs. A. J. Watson dominates the exhibit, while Mrs. Townley Parker, Nora Ferguson, the azure Constance, and the puce purples Mrs. Colin McIver and Lord Derby are among those specially worthy of note. Fairy Queen, which has been relegated to a back corner, is a fascinating thing which can best be described as a clean pinkish lilac with a dark brown "bee."

Messrs. G. Gibson and Co. have a group largely alpine in character, but containing such border favourites as Thalictrum culture, and their giant form of P. Littoniana is a giant indeed, and a drift of a couple of dozen plants on their tabling is as remarkable a sight, in its way, as anything to be seen at Chelsea. Among a group of gaudily coloured candelabra primulas the soft yellow P. sikkimensis looks delightfully cool, as do plants of the hardy maidenhair, Adiantum pedatum.

Mr. G. W. Miller in a rather congested group shows some well flowered if rather loose-pet alled polyanthus.



LUPINS AND HERBACEOUS PLANTS SHOWN BY MESSRS. WATERER, SONS AND CRISP.

aquilegifolium purpureum, Anchusa myosotidiflora, Ranunculus speciosus plenus and R. aconitifolius fl. pl.

Messrs. Maurice Prichard and Sons have a fine bank of herbaceous stuff in which named groups of the Bartley strain of pink Primula pulverulenta play a prominent part. A gigantic hybrida primula, obviously of pulverulenta kin, but of a glowing cardinal red toned with terra-cotta and called George Thursby is another notable feature of a group which includes excellent lupins, trollius and camascias, Dielytra spectabilis and other desirable things.

The adjoining group by Messrs. John Waterer, Sons and Crisp displays most effectively Anchusa italica in the varieties Opal and Pride of Dover. Many fine herbaceous lupins, including the well named Dresden China, the violet-purple Happiness, Opal in delightful lavender tones, the deeper coloured Penelope, the blue and white Mayflower, Pink Pearl, Delight and the Sunshine, the last named a good yellow of the Somerset clan, but a great improvement on that now out-dated variety. Mulleins, too, are well represented in this exhibit, these including Verbascum densiflora and the pale buff apricot W. Walker. Trollius and long-spurred columbines are also well represented.

The Chalk Hill Nursery show some of their specialities on the cross-staging. These include fancy pansies, a few violas, the Chalk Hill giant mimulus (a very useful and brilliant flower for wet borders or waterside), candelabra primulas and long-spurred columbines.

The adjoining contribution from Messrs. Bakers is mainly alpine, but Incarvillea grandiflora, the inevitable bog primulas, including in this case helodoxa, Thalictrum aquilegifolium, lupins and columbines will hardly fall into this category.

Messrs. Oliver and Hunter find their cool Scottish climate favourable to primula

Messrs. Reamsbottom display their wonderful strain of St. Brigid anemones with an effective background of black velvet and interspersed with fern.

Messrs. B. Ladhams, Limited, have all sorts of unlikely things, such as Nepeta Mussini, the old red double daisy and Spanish squills arrayed in baskets.

The Maytham Gardens have a veritable spring border planted with peonies, campanulas, irises and so forth, but the juxtaposition of auriculas, bog primulas and bearded irises does not seem a happy one.

Messrs. Sutton's great group of flowers from seed includes the finest lot of snapdragons (antirrhinums) ever seen at Chelsea.

All the forms of the Welsh poppy, Meconopsis cambrica, combine to make a drift of orange and lemon on the table space occupied by Messrs. W. H. Rogers and Son, Limited, and healthy plants of Primula helodoxa and, once again, of the Bartley strain of Primula pulverulenta lend diversity to a fine group mainly consisting of rock plants.

The Blakeney Nurseries have quite a bank of that brilliant bedder Dahlia Coltness Gem.

Mr. T. Carlile has an early summer border, containing a good variety of lupins, with Pentstemon Bridgesii, Geum Heldreichii magnificum, globe flowers, thrifts and so forth. Groups of small plants of various brooms are introduced to lend variety, and, where labour allows, small plants of such flowering shrubs might be used (plunged in pots) to fill spaces left for later flowers.

Messrs. Hewitt are showing irises, tulips and a few early spikes of their famous strain of delphiniums. One of the finest of the delphiniums is a splendid deep blue shaded with purple called Evening; another particularly rich lilac is King Bladud; while there is a magnificent white called Mrs. Christie Miller These fine delphiniums are noted for their grace.

Messrs. Rich and Co. are staging a small exhibit of excellent quality of tulips, Sunbeam poppies and violas.

Mr. John Forbes has a fine exhibit of East Lothian early stocks. This is a famous strain, the colours are vivid and good. He is also showing the fine Dahlia Coltness Gem, Statice Butcheri and violas along with a fine form of Primula Sieboldii.

DAHLIAS

Considering that we have, as yet, hardly passed the middle of May, Messrs. Carter Page's circular group of dahlias in the big tent is a thing to wonder at. If things progress at this rate, we shall all be growing dahlias for conservatory decoration, instead of Malmaison carnations. The decorative and pompon sorts are most successful and the plants of Barlow's Bedder, Glut, Vrijbuiter, Crimson Flag, all crimson or scarlet decoratives, and of the self-descriptive pompon Chamois Rose, are especially noteworthy but brilliant "Mignon" Coltness Gem, the collerette Scarlet Queen, and, indeed, representatives of almost every section, are to be found here in fine form.

Messrs. J. Cheal and Sons also have quite a collection on staging on the other side of the great tent, but for the most part this takes the form of cut flowers. The Mignon and Star forms are here well to the fore, including such well tried favourites as White Star, Cuckfield Star and Ifield Star. Quite presentable vases of the Cactus sorts, Mrs. F. Paton, Sweetbriar and Mrs. E. Lowes, are also noteworthy.

GLADIOLI

The day is not yet, apparently, when the gladiolus will emulate the dahlia and become a spring flower. A vase of a variety of apparently primulinus origin, a shade or two paler in colour than Fire Queen, and shown by a Dutch firm towards the bottom of the great tent, and three or four nice spikes of primulinus hybrids on Messrs. Lowe and Gibson's border carnation exhibit, are, barring two or three vases of the Colvilei section in Mr. E. Scaplehorn's plant group, the only representatives of the flower on view. The Bishop, Lovely, Joy Bells (all heliotrope as forced) and Coquette particularly attract attention of this set, while the older King Bladud and the almost amethystine Lorenzo de Medici are equally effective in their way.

ROSES

The exhibit of Charles Turner, Slough, consists very largely of forced dwarf, half standard and standard roses, some of them hardly ready for exhibition, as the earliest flowers are not expanded, but all fresh and interesting.

Messrs. A. and C. Allen have a much showier group, which, unkind weather conditions notwithstanding, is quite "up to the knocker" for show day. Fine specimens of the coral pink Havering Rambler suggest a fully double Coquina, but makes a stronger appeal than that rather sleepy-eyed sort. The yellow Mrs. Beckwith, the pink Souv. de Georges Pernet, very pretty as forced, and the ubiquitous Ophelia, are noteworthy in a most attractive group.

Mr. Elisha J. Hicks' great bank of roses is another treat in store for every visitor. The backing includes great masses of growing ramblers, such as Paul's Scarlet Climber, Tausendschön, White Flight, and the Blush and Crimson Ramblers, the last named many degrees off its normal outdoor colouring, but the others wonderfully true to colour-tone. A fine group of plants of America at once catches the eye in the

Digitized by Google

foreground, as do two pillars of cut flower, the one Mme. Butterfly, the other the beautiful white Mrs. H. Stevens. A basket of giant blooms of Clovelly is another outstanding feature, while Molly Sharman Crawford is also wonderfully well shown. These, however, are but a few of an immense and exceedingly interesting collection of varieties in a capital effort.

Messrs. Benjamin R. Cant and Sons, Limited, have a relatively small bank containing a fine group of plants of the golden Souv. de Claudius Pernet, two new seedlings, the deep citron Mrs. Beatty, which is delightfully fragrant, and Lady Wakefield, a pretty copper apricot sort which, as far as the flower is concerned, reminds one of Mrs. A. R. Waddell. Columbia and the new polyantha Orange King are also to be seen in good form.

The Rev. J. H. Pemberton occupies a length of tabling with a very taking group of, generally speaking, dwarf polyantha varieties. The pale salmon pink Julian, Henry Nevard will be too blue a crimson for most folk's liking, but Mrs. Wemyss Quin and Lady Roundway are surprisingly good. Standards of the brilliant polyantha La Reine Elisabeth lighten and brighten an interesting group.

Mr. George Prince has a nice little table group, containing such tried if not old, varieties as Columbia, Mme. Butterfly, Hoosier Beauty and America. The fine polyantha Coral Cluster is well shown; so, too, is the grand old Banksian Yellow; while the new and fragrant blackish crimson rose Sensation and the golden Souvenir de Claudius Pernet occupy a position of honour.

Messrs. Ernest Paul have a small collection of roses among their exhibit of tulips. Many of the well known varieties, such as Covent Garden, Golden Ophelia, Molly Sharman Crawford, Richmond and Butterfly are exhibited.

Mr. W. Paul has a large collection of roses. Standard Mrs. H. Morse and Richmond are shown. A small bright red dwarf polyantha,

SOME OF MESSRS. ALLEN'S ROSES.

Corrie Koster (which is decidedly paler and has a better flower than Orange King), the starry, bright-eyed Chatillon Rose and the semi-single White Echo with blossoms 3ins. across share honours with Baby Faurax, the most endurable "blue" rose we have so far encountered, the brilliant crimson-scarlet Topsie, Ellen Poulsen and the shell pink Pink Echo, a counterpart of White Echo to which reference has already been made.

Messrs. William Cutbush and Sons have their usual fine array of dwarf polyanthas with fine specimen weeping and other standards to diversify the group. Salmon Queen, Chatillon Rose, Ellen Poulsen and the nearly blood red Superba are shown in capital form. A climbing polyantha known as Red Explorer and shown in pillar form should not be overlooked.

Messrs. Frank Cant and Co. have a nice bank of quality roses. Captain F. S. Harvey Cant is shown in good form, so is the velvety crimson Lord Charlemont and that most gorgeous of golden roses, Mabel Morse. named Ideal, is a good variety. Paul's Scarlet Climber, Rev. F. Page Roberts and Golden Ophelia are much in evidence.

FRUIT AND VEGETABLES

Probably the most tempting display in the whole show, especially in these hot days, is that provided by Messrs. Laxton Bros., of strawberries in pots and also gathered fruit. They do make one's mouth water with expectancy. Among them are to be found many of the older varieties, such as Titbit—a 1924 variety of good size and flavour—The Duke and Abundance. There are three new strawberries, however, which call for a word. Robust, as its name implies, is a robust grower, ripening in mid-season. It is a fine fruit of good size, colour and flavour. Another excellent new introduction is Laxton's Empress, which may be regarded as an improved Vicomtesse. The fruit is firm, an excellent asset for preserving and for dessert. Number three is called Laxton's Rearguard, no doubt on account of its late fruiting properties. It is a cross between Laxton's Latest and Omega, and surpasses its parents in colour, crop and flavour. It appears to be of excellent constitution. This exhibit altogether is a very fine one considering the backwardness of the season and the lack of sunshine which has been experienced throughout the country.

Messrs. Rivers and Son, Limited, are staging their usual large collection of fruit trees in pots. Peaches, nectarines and plums are to be seen all heavily laden with fruit, such varieties as Peach Duke of York, and in nectarines, Cardinal, Early Rivers, John Rivers, and Blue Rock in plums are noticeable. The fruiting capabilities of some of these varieties exhibited are beyond question.

A fine exhibit of raspberries is staged by Mr. V. C. Vicker of Herts. Here again one wants to linger in the hope that a fruit may chance to drop and so satisfy one's curiosity regarding its flavour. Well fruited bushes of the new raspberry Viking are staged. This is an excellent forcing variety, as is also the new yellow fruited variety, Amber. The arrangement is good as the fruiting capacity of the bushes is well shown.

Another amateur with a fine exhibit is the Hon. Sir John Ward of Hungerford. Here we have luscious bunches of Black Hamburgh and Foster's Seedling. These are well formed bunches with the individual fruits of medium size. Strawberries are also present in two varieties, Royal Sovereign and King George V, while peaches and plums are also represented by Hales Early and Early Rivers.

From the Aldenham House gardens there comes once again a very fine exhibit of high-class vegetables. Mr. Edwin Beckett has once more excelled himself, if that can be possible, in the production of this wonderful collection of vegetables. How every amateur must sigh to be able to produce such well grown varieties of each of our staple food crops. Every vegetable dish appears to be represented and although it has been said many times before, yet once again must we offer our congratulations to Mr. Beckett, both for the high standard of excellence reached in cultivatio and for the arrangement of his group.

A comprehensive collection of potatoes, consisting of between thirty and forty varieties is staged by Messrs. Sutton and Sons. Among these varieties can be noted splendid dishes of Sutton's Early Market, Sutton's Epicure, Ben Lomond, Stirling Castle, Carisbrooke Castle, etc. An exhibit of potatoes so early in the year is both interesting and instructive, as it serves to show what may be accomplished in the production of such a valuable food crop.

Apples are again in the capable hands of Messrs. Bunyard, who stage a fine array of many excellent varieties in baskets. The high quality of the fruit shows how the question of storing is of such importance. Above all, a cool and stable temperature is required. Such varieties as Barnack Beauty, Sir John Thorneycroft, Ontario, Wagener and Jonathan, are there, and all in excellent condition.

Our front cover is taken from pinks kindly supplied to us by Mr. C. H. Herbert.

In next week's issue we shall publish detailed comments on Rock Plants and Primulas, Stove and Greenhouse Plants, Orchids, etc., and Garden Sundries, with descriptions of New and Rare Plants.

No. 6

The Cricket Club Secretary

Ugbrooke,
Chudleigh.
S. Devon.

April 1,24.

Dear Sirs,

You may be interested to see from enclosed report that your Atco Mower has been a great success and a saving compared with horse hire.
Our ground has been selected for a County Trial match - on account of its excellent condition; this is mainly due to your machine.
I saw your Cultivator attachment while at Olympia last month - and have a leaflet about it.
Can you give me particulars as to price? I am anxious to get one, but could we pay by instalments as we are not a rich club and could not run to a big outlay now.

Yours truly,

G. Hammick

Men who appreciate The ATCO MOTOR MOWER

In the letter reproduced above the Secretary of one of many Cricket Clubs using the ATCO Motor Mower expresses his opinion of the machine. Let us prove ATCO claims by arranging a free demonstration on your own grass without obligation.

WALLACE'S LILIES and IRISES

We welcome visitors to our Nurseries at all times, and especially in June, when the slopes of "The Old Gardens" will be alight with many thousand Iris spears and shafts. We are confident that Iris lovers will find our fine collection of the greatest interest.

LANDSCAPE and GARDEN ARCHITECTS

This department is under the personal supervision of Mr. R. W. WALLACE, V.M.H.

We prepare plans and designs and carry out landscape work for new grounds or for renovation of old gardens. The construction of rock work and making of water gardens is undertaken in any part of the country or on the Continent.

MELON CULTURE

IF we were living in certain parts of the United States it is doubtful whether notes on melon culture would have any utility, for the practice seems to be that of sowing seed on mounds of soil, and just waiting for the fruit to appear, and they certainly grow a vast quantity, being, I should imagine, one of the principal melon consuming nations in the world. In the British Isles, where climatic conditions are considerably different, it is another proposition to grow melons with the most complete success, and decidedly a more expensive matter in these days of dear fuel, but a good crop of well grown excellent fruit is a sure reward to those who undertake the task. With a view to assisting those who wish for success with this luscious dessert, it is as well to remark that it is not advisable to attempt to grow melons at the same time, and in the same structure as cucumbers, which is often done, for, although cultural methods are closely allied, yet, atmospheric conditions for the two fruits require to be different. Both are species of the same genus (Cucumis sativa, the cucumber, and C. Melo, the melon), but one is eaten as a ripe fruit, while the other is a green salad, hence the call for differing atmospherics.

The melon, which was introduced to this country about the year 1570, is a native of Asia, in particular the Himalayan regions, and this fact has an important bearing in its culture, for, exposed to the strongest sun in its native haunts, it will be understood that even when raised under glass in this country, the temperature and strong sunlight will not adversely affect it, and therefore shading under such conditions is not necessary, although this is frequently done. Even the heavy moisture which is prevalent in the atmosphere at certain stages of its growth is not inimical to it, for such stagnant humid heat often prevails in the regions from whence it comes. There are many different forms of the melon, but in the present notes we will only consider the generally cultivated forms, raised and in general use in this country. The great aim in the growing of this fruit should be to keep the atmosphere as buoyant as possible at all times, and when it becomes too heavily charged with moisture, then careful and attentive ventilation should be carried out, in order to correct this.

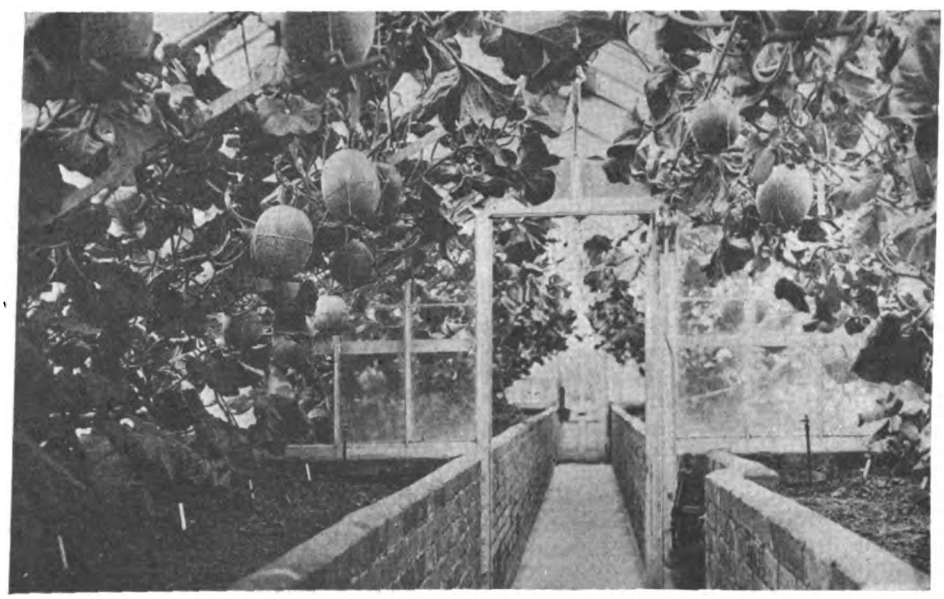
A start should be made by raising seedlings at the end of February or beginning of March, placing one seed in a good turfy mixture, in 2in. pots, and placing on a bed where bottom heat is prevalent, to germinate. The temperature for this should be between 70° and 75°, and once germination has taken place, then the young plants, throughout the rest of their career, should never be permitted to become dry at the roots, though watering will have to be controlled at various stages of growth, more being required at certain times than at others.

The bed should be prepared for planting into in March, and the compost should comprise three parts good turfy loam, one part well decayed horse manure, two parts clean road grit or sand, and half a peck of crushed charcoal to every barrowful of this mixture. The sand is a most important ingredient, for the aim should be to maintain the bed in a sound condition throughout the life of the plant, and this can only be done if the bed is properly porous.

Training is often a matter of controversy. Some growers like to pinch out the points when 6ins. high, and aim for two growths, but I prefer the one growth throughout, tying this carefully to the trellis wires for support. When the plants flower, hand fertilisation is necessary, removing the male flowers to fertilise the female ones, and once three or four good fruits are set, I look on this as being the correct burden for the plant to carry. All the growths which follow should be stopped, and it is advisable not to do this all in one operation, as it will probably prove too severe a strain on the plant. Dry air is essential during setting, and slight ventilation should be given during the whole of this period. Lateral growths should be stopped at a joint beyond the fruit, and not more than one fruit allowed to a lateral growth. Watering should be sparingly carried out at the start, but may be more freely done once swelling begins. When ripening commences, too much water is harmful and air becomes important again at this stage. Syringing should be done twice a day, both before and after fruit setting has taken place, to assist growth and to keep down the harmful red spider, which will attack the foliage if the atmosphere is too dry. The floor of the house should be well damped down to assist in these matters, but again cease these two operations when ripening commences.

The fruit should be supported from quite a small size, and for this either nets or boards can be used, the writer's fancy turning to small squares of deal, tied at the right levels properly to support the fruit, by strong string to the trellis wires. At the ripening period cracking round the stem of the fruit will denote the time to remove from the plant, for completing the process off the vine in the drier atmosphere of a fruit room.

One point that should be noted as advantageous is to do the fertilising of the four fruits, or as many as it is decided to permit the plant to carry, at the same time, so that all start comparatively equal and thus do not handicap each other. Cutting out should also be carefully regulated, for wholesale slashing out of superfluous growths will probably assist that dreaded melon pest, canker, to get a hold, and the plants should be carefully handled in the early stages, as the disease is possibly permitted to affect the plant through a scratch or knock to the stem, aided perhaps by heavy, incorrect atmosphere and insufficient drainage of the bed.



MELON FRUITS SUPPORTED BY MEANS OF NETS AND BOARDS.

To aid the swelling of the fruit, weak liquid manure may be given to the plants, changing occasionally with a reliable fertiliser, and alternating with the applications of clear, tepid water. All liquid applied should be of a temperature approximate to that of the bed. Cold, chilling water should never be given as it checks the plants badly.

Melons may be successfully grown in heated pits and frames on hot beds, and for the latter purpose the bed should be made up, about a fortnight before planting, of fresh fermenting material, such as long stable litter and suitable leaves mixed. In this method of growing it is preferable to allow the plants to wander loose on the bed, training and setting, as well as handling generally, in the manner approved for culture in a house. The fruits can, in this case, be laid on a tile

Digitized by Google

or slate, using means to prevent them from rolling as they grow.

Those wishing to continue the supply during autumn and winter should raise a batch of seedlings about mid-June, to take the place of the other plants as their fruits mature, and they are past their stage of use, but I do not think that melons that ripen during late autumn and early winter are really worth the trouble that has to be bestowed upon them.

There are many good varieties of melon, but I still look on the old Hero of Lockinge, a white fleshed variety, as the very best we have. A good green fleshed variety is Emerald Gem, which has unusually thick flesh, of excellent aromatic flavour. Four scarlet fleshed varieties appeal to me as being ahead of the others, and they are King George, a strong growing form with very thick flesh and heavy weight; Superlative, a medium sized variety, of very rich flavour; Blenheim Orange, with deep, solid flesh and thin, even rind; and Reed's Scarlet Flesh, another variety of very fine flavour. EDWIN BECKETT.

PLANT PROPAGATION IN THE TROPICS

BY DR. R. J. D. GRAHAM.

"IN TROPICAL REGIONS VEGETATIVE PROPAGATION IS AS YET BUT LITTLE EXPLOITED."

A FEW weeks ago it was my good fortune to hear the presidential address to a horticultural society. The subject chosen was plant improvement, and there was an indication that such work was peculiar to the West and was practised but little, if at all, in the East. My mind turned to what I had seen in the vast rice fields of India with the multitude of different kinds of rice cultivated there. Each rice bears its own native name, and the different kinds are each recognised by head marks known to the cultivators. Seven hundred vernacular names in one province and over a thousand in another indicate considerable skill in plant breeding. In no agricultural crop in the West has breeding work been carried to such a point. One has to turn to roses, sweet peas or some other garden favourite to get anything at all approaching the fine points of distinction which differentiate one rice from another. Such intensive plant-breeding owes nothing to the West. It is an indigenous product of India, its origin lost in the mists of the past. Plant improvement in the West has found its highest expression in horticulture, attention having centred on the development of form and colour. In the East the needs of the inner man have forced attention to one of the staple food crops, establishing an even richer number of types.

The quotation standing at the head of this article appears in the printed abstract of one of the papers read at the Imperial Botanical Conference last July. Again the mind is led back to what one has seen in India. Without claiming any superiority, but as an instalment towards the debt due to the chance that carried one abroad, the quotation may serve as a text to a survey of things as they are in the fields and gardens of India.

Sugar-cane is a reed-like grass which grows to a height of 10ft. or 12ft. One group of canes includes all the thick canes, while the thin canes form a separate class. Within the two classes there are numerous varieties. Some canes flower annually, others but rarely, and in either case very little seed is ever obtained. The millions of acres of canes necessary to sweeten our lives are all grown from cuttings. True, there was a dear lady once who thought thick canes were grown from loaf sugar and thin canes from castor sugar!

Sugar cane, like potatoes, is often cited as an example of a plant which deteriorates through continued vegetative propagation. Recently much work has been done in the West Indies and in India in raising seedling canes. There is no doubt about the need of disease-free canes, just as there is no doubt about the need of immune potatoes. One is tempted to suggest another source for the deterioration when the cultural conditions meted out to either crop are considered. Both sugar cane and potatoes are, to all practical purposes, grown upon manure. May it not be this over-cultivation which is the root of the trouble? Over-cultivation lowers the resistance of both plants to disease, and disease is followed by deterioration.

THE METHOD OF PROPAGATION KNOWN AS MARCOTAGE.

Another crop of the tropics raised continually from suckers is the banana. Seed is rarely produced in the cultivated races of banana, and when unexpectedly found stands little chance of being saved for sowing. In my wanderings I have only once met a man who chanced on a seed of a cultivated banana. A broken tooth had obscured the scientific value attaching to the discovery. Without vegetative propagation in the tropics the answer to the popular song anent bananas would be true. The banana may well be held up to those who see evil inherent in vegetative propagation. From the earliest records, so far as one can learn, the banana has been continuously and successfully raised vegetatively.

Tapioca or cassava from Manihot utilissima—a near relation of a rubber-producing tree-arrowroot from Maranta arundinacea—with vanilla and ginger to flavour them, are propagated by division. Yams and sweet potatoes, poor substitutes for the real article, are grown from cuttings of the vines or from tubers.

Turning to fibre-producing plants, we find the yuccas and the agaves in India propagated vegetatively, as also is the bow-string hemp, Sansevieria zeylanica, and the ramie fibre plant, Bœhmeria nivea, used nowadays for incandescent gas mantles.

Nor is the Indian fruit-grower behind his Western brother in skill in his craft. Though fruit trees can be grown from seed in India as at home, recourse to vegetative propagation is made to secure earlier maturity and consistent quality of fruit. Among the fruit trees of India perhaps the best known is the mango, through its association with native conjurers and Indian chutney. The best varieties of mango are invariably perpetuated vegetatively. The commonest method is by grafting by approach or inarching on to seedling mango stock, but grafting is also carried out. The guava, a fruit possibly more popular in the form of jelly than in the fresh state, is best propagated by layering. The orange is propagated by budding except in Assam, where trees bearing good oranges are raised from seed. The owner of an orange grove knows the uses of various stocks for his orange plants and will discuss the advantage of sweet lime over sour lime or sweet orange and sour orange as alternative stocks. The lichee, a Chinese fruit now cultivated largely in certain parts of India, is propagated by a gootee, which corresponds to the form of layering in a pot or ball of moss called marcotage in this country.

The custard-apple and the bullock's heart or sweet sop are raised from seed; but the loquat is grown either from seed or by grafting. The rose-apple, Eugenia Jambos, is layered; and the jujube, Zizyphus Jujuba, is grafted; while the sapota or sapodilla, Achras Sapota, is in-arched like the mango. Sub-tropical and temperate fruits such as the fig, pineapple, apple, pear, mulberry, vine, plum, peach, strawberry and loganberry, are raised in India in much the same way that they are grown in this country.

GEMS for the GARDEN!

GOLD MEDAL BEGONIAS. Gorgeous Colours for Exhibition or Bedding Double or Single, Red, Carmine, Gold, White, Pink, Bronze, Lemon, **2/6** per doz.; **17/6** per 100, carriage paid.

ANTIRRHINUMS. Strong Bushy Plants, now ready. The Bride (pure white), Cottage Maid (pink), Golden Queen (yellow), Blood Red (dark crimson), will make a glorious show. **2/6** per doz. Smaller Spring Plants, **1/-** doz.

GERANIUMS! GERANIUMS! Order early to secure good plants. Paul Campbell, Denmark, Raspail, Ivy, scented-leaved varieties, etc., **4/6, 6/-** and **9/-** per doz.

PHLOX FLAME FLOWERS. Lassberg (snow white), Lottie, Kohler (white, red centre), Iris (mauve), Rynstroom (large pink). Eclaireur (carmine, salmon centre), Jean d'Arc (fine white), America (pink), Asia (rosy carmine), Eclair-vonde (blue), and many other fine varieties, **5/6** doz.

PEONIES. Full of flower buds. Pink, White, Red, Yellow, large clumps' **5/6** doz.

ANEMONE JAPONICA. Lovely shades, splendid for cutting. **2/6** doz.

VIOLAS. A Fine Selection, **2/-** doz. Molesey Perfection, Archie Grant, Maggie Mott, Primrose Dame, White Swan.

CALCEOLARIAS. Golden Gem, a Special new Large Yellow type, fine plants' ex. 48s, **3/6** doz. Very bright bedding variety.

FUCHSIAS. We have a special fine line to offer in Double and Single varieties, all very strong bushy plants, **4/6** doz.

MARGUERITES. Single White, Double White and Yellow. Fine Plants. **3/-** per doz. Also Blue Marguerite, **6d.** each.

POTENTILLAS, 4/6 per doz., **6d.** each. Orange and Scarlet, with large double blooms, resembling a glorified Geum.

ROCK PLANTS. A fine selection of Alpines for Rockeries. Sempervivums, Veronicas, Aubrietia, Heuchera, Sedums, Thymus, Ajuga, etc., **2/6** doz. named.

PENTSTEMONS. Fine Strong Plants, fine mixed varieties, lovely colourings, **3/-** doz.

ALL 6d. per Lot: 12 Asters (all varieties), 12 Stocks, 6 Sweet Williams, 3 Veronicas (various), 3 Michaelmas Daisies, 3 Achillea tomentosa, 12 Sweet Peas, 3 Sedums, 3 Chinese Lanterns, 6 Arabis, 6 Variegated Grass, 2 Vinca, 1 Thalictrum (Hardy Maidenhair, large cup), 12 Marigolds (French), 10 Marigolds (African Tall), 3 King Edward Daisy, 1 Lilium candidum, 1 Lilium tigrinum, 12. Chrysanthemum Coranium (white and gold). 6 Scabious, 1 Red-hot Poker (**4/6** doz.), 6 Alyssum, 6 Carnation-flowered Polys, 6 Nigella, 6 Mignonette, 12 White Lobelia, 12 Blue Lobelia, 2 Lobelia cardinalis, 4 Sunflowers (autumn single variety), 6 Double Yellow Sunflowers (Dwarf), 3 Nicotiana, 1 Heliotrope.

VEGETABLE PLANTS. 50 Cabbage, **6d.**; 25 Cauliflower, **6d.**; 50 Lettuce, **6d.**; 4 Marrow, 1 Cucumber, **6d.**; 6 Mint, **6d.**; 6 Thyme, **6d.**; 3 Silver Thyme, **6d.**; 12 Tomato Plants, **2/6,** carriage paid; Kondine Red, Ailsa Craig, Sunrise, Comet, M. J. Clarke's Masterpiece, a fine heavy-cropping variety (12lb. from 1 plant), Early Fruiting, **3/-** per doz.

EARLY-FLOWERING CHRYSANTHEMUMS (our speciality), Sanctity (white), Perle Chat. (gold, shaded pink), Normandie (rosy pink), Martin Reed (golden yellow), Almirante (old gold, shaded bronze), Polly (flame) and several other lovely varieties. 12 in 6 varieties, fine plants, named and carriage paid, **2/6.**

GREENHOUSE PLANTS. No Heat Required. 1 Sparmania africanus, **1/9**; 1 Abutilon Thomsonii, **1/6**; 1 Kalanthus coccinea, **6d.**; 1 Cyclamen, **6d.**; 6 Tradescantia, silver or gold, **6d.**; 1 Nice Strong Palm Cordyline, **1/-**; 3 Bridal Wreath, **6d.**; 6 Beautiful Ferns, assorted, **3/-**. Post free.

SALVIA! (Flamingo.) A glorious new variety, large spikes of dazzling crimson blooms, and a continuous blaze of colour from June to October, **7/6** per doz.; Salvia Pride of Zurich, **6/-** doz. With these grow **Centaurea candidissima,** a striking silver foliage plant, a charming contrast, **6/-** per doz. plants.

Please give your full **rail address,** and when not stated carriage paid, please add extra to pay carriage. Orders from **1/-** to **5/-, 6d.** extra; **5/-** to **10/-. 9d.**; over **10/-** please add **1/-** extra.

Small parcels sent by Parcel Post. Do not fail to give correct address and nearest Station. This is a great help to us in despatching.

In garden practice the native gardener or *mali* uses all the wiles of his Western *confrère* to perpetuate plants which are shy seeders or which do not come true from seed. Cuttings are made where the subjects lend themselves to treatment in this way. Plants too tender to be treated in this manner are layered, but the method dear to the *mali's* heart is the gootee. In the rains it needs no attention, and, being a method of propagation little known to many Europeans, creates an interest in the *mali's* work which pleases him, and which may produce a tangible reward in the way of *backsheesh*.

The Arab in Mesopotamia is another exponent of the value of vegetative propagation. The date palm is almost always raised from offsets. True, the date contains a viable seed which, if sown, will give a date palm. The Arab applies to this the same term as to weeds, for the seedling palm is slow to fruit, and when it does eventually do so the dates are not the same as those of the parent tree. Many of the seedling palms will turn out male trees, bearing no fruit at all. The pomegranate is grown from cuttings, as also is the mulberry, to cite but two examples from the many which could be mentioned from the trees in the gardens of Eden. The olive trees in the north of the country are grown from cuttings, as also are the white poplars planted in woods in the valleys of the Kurdish hills. So rapid is the growth of the poplars that the Turks taxed the plantations after the fifth year.

Thus we have, then, in the East and in the West the same methods of plant improvement practised. Generally the methods have been developed independently, but at times one can see an influence of West on East or East on West. The methods have been applied both in the East and the West as the needs of the peoples have directed. Seed selection has been applied to food crops in India, and the cultivator will tell which rice digests most slowly because by sowing it he will only have to eat once in the day. Fruit trees have been the object of special attention, and here vegetative propagation has been exploited by native methods differing in no respect from those used at home. That white settlers and planters have not applied these methods to economic crops which they grow is no ground for imagining that the native has similarly failed.

FRUIT PROSPECTS IN 1925

FROM the point of view of fruit-buds and blossoms, it is many years since the fruit prospects were brighter than they are this year. Though many factors have to be considered after a plentiful supply of fruit-buds and later the bloom before a crop is assured, yet without this all others would obviously be useless for the year. There is therefore good reason to be hopeful about this year's fruit crops.

Plums, the latest varieties of which are in bloom here (Berkshire) as I write (May 9th), have been a wonderful sight.

Apples, the earliest varieties of which commenced to unfold their blossoms this week, fully ten days later than usual with us, are for the most part crowded with healthy flower-buds, and in a week or two should present a fine sight. Cherries, locally, appear to be flowering profusely. Pears by general consent are the least promising of the kinds named. It appears, however, to apply more to trained trees than to large standards. Trees on walls and fences are only blooming moderately, but the bigger trees in the open are much better, many trees being laden with flowers. Peaches flowered well in this neighbourhood, and have generally set good crops. Apricots, which are not, perhaps, so much grown now as some years ago, probably owing to the trees' bad habit of losing branches, are moderately cropped. Optimism prevails over bush fruit. Gooseberries, black and red currants are most promising, and the same applies to raspberries.

A close inspection of the strawberry quarters reveals a more cheerful prospect than was the case at one time. The plants did not look any too well during the continued wet weather of the winter and early spring, but they seem to have come along wonderfully this last month, and good flower-stems now appear fairly plentiful.

Though, as previously mentioned, flowers are of first importance, every grower of experience is aware that it is too early yet to count his chickens. There are the vital factors of pollination and weather to play their part—for or against—and the latter has a great bearing on the former. Pests, too, are always more or less liable to reduce a crop, but can be generally combated by watchfulness and application. Pollination is linked up with the period of blooming, since many varieties of apples, pears, plums and cherries have long since been proved to be sterile to their own pollen. Where mixed varieties are grown the danger of fruit not setting is, of course, very largely minimised. To ensure a set in such cases it is necessary to have other varieties blooming at the same time and the weather favourable for pollination. Honey bees, humble bees, other insects and wind will do the rest.

A close inspection of the plums gives one every reason to expect a good crop, for many varieties appear to have set. It is too early to be unduly optimistic. The weather, which plays such a big part in the setting, and raises or lowers the hopes of fruit-growers according to its vagaries, has up to now not been so bad. True, we have not had any very genial, warm days, and we have had slight frosts on several occasions, but against that is the fact that for the main part it has been dry, with, at any rate, occasional spells of sunshine. I have carefully noted the activities of the honey bees, and at every sudden spell of sunshine, be it ever so short, they have appeared on the trees as if by magic, and were worthily upholding their character as busy bees. In their absence we have had the valuable assistance of humble bees, who are, fortunately, less particular as to weather. Very heavy hailstorms have been experienced in some localities, and in such places there must be apprehension as to the safety of the plum crop. On the whole I shall be somewhat surprised if the plum crop is not a good one and very possibly a bumper one.

Apples are flowering much later than usual. Records prove that many popular varieties, such as Cox's Orange Pippin, James Grieve, King of the Pippins, Worcester Pearmain, Bramley's Seedling, Lord Derby, Pott's Seedling and many others have been in full flower here between the dates of April 30th and May 10th. This year not one of those varieties has so far expanded any blooms with us, though, of course, a few fine warm days would bring about a transformation. In our fickle climate we never know when a catch frost may not come and do untold injury.

A careful watch for pests has not revealed anything serious to this date. A few caterpillars of the winter moth and aphides have been noticed on plum trees, with the addition of a few suckers on apple trees. This comparative freedom from attack may be largely due to grease banding and winter spraying with egg-killing washes. Last year fruit trees were wonderfully free from insect pests, following an unprecedented attack in 1923. Is it too much to expect a repetition of last year's comparative scarcity? No time should be lost in spraying the trees whenever the pests named are observed, providing the trees are not in bloom. This precaution is important, since, to be effective, a poisonous spray—such as nicotine or arsenate of lead—will have to be used for caterpillars and apple suckers, and the danger to our friends the bees when visiting the open blossoms of trees so sprayed would be terrible. The apple is subject to more pests than other fruits. In addition to those mentioned, the caterpillar of the codling moth, commonly known as the apple maggot, can do untold damage if present in numbers and unchecked. This moth lays her eggs in the eyes of the fruit, generally one to each fruit. As each moth may deposit over a hundred eggs, and these in turn produce as many caterpillars, and as each if allowed to continue its life would enter one apple, which it would partly or totally spoil, it does not need much imagination to realise the possible effect of this pest on the apple crop. No time should therefore be lost in spraying after the blossoms have fallen.

Gooseberries and currants are often injured by aphis much in the same way. This troublesome little pest invariably attacks the youngest part of a shoot, viz., the tip. It is often possible to control them by dipping the points of the shoots into a pail of insecticide, and is much more economical than spraying the whole tree.

In districts where late frosts are liable, the early blooms of strawberries are often ruined. In gardens it might be worth while strawing the plants early and netting the beds before the earliest and best blooms open. ARTHUR J. COBB.

SIMPLE GARDENING

SUMMER SALADS.

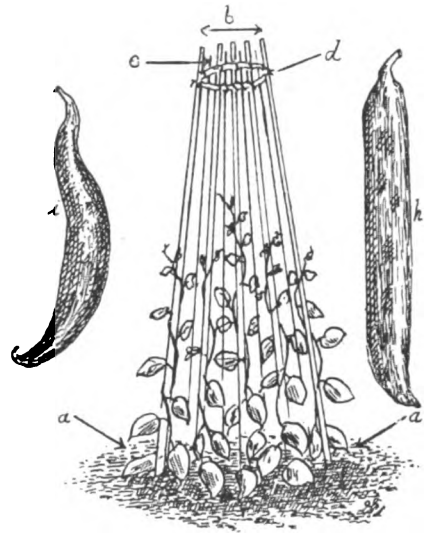
WINTER and spring salads cannot be grown very successfully without the aid of frames, at least, and to secure a good succession and variety, heated structures are necessary. Salad plants like heat, but they fail to do well unless there is sufficient moisture as well. Given these conditions it is not difficult to grow good salads in the summer. But, unfortunately, such conditions do not obtain every year, so the cultivator must, then, make them artificially, as it were. The plants must be quickly grown to secure that fresh, crisp, succulent condition so much desired. Celery is always welcome, for flavouring as well as for eating. The earliest sticks may be grown in a frame. After clearing away winter and spring tenants, rather than allow a frame to remain empty, make up a bed of rich soil 1ft. deep, plant celery 1ft. apart, feed regularly and blanch by tying paper round the stems. Keep on the glass lights during the first few weeks to draw up the plants. Lettuce should be planted in a deep, rich soil, while quite small. It is a good plan, too, to sow seeds in drills and thin out the resultant seedlings to 9ins. apart; there is then no check. Ridge cucumbers should be grown on flat-topped beds of rich soil, and frame varieties in frames, keeping the lights almost closed and securing heat and moisture. Radishes require a medium rich soil and a good depth. Sow the seeds thinly and a few, only, every three weeks. Grow mustard and cress in very rich soil on the north side of a wall or fence, and tomatoes on the hottest side. Leave a few beets 2ins. apart and thin them for use in August.

PLANTING OUT CHRYSANTHEMUMS FOR LIFTING.

These notes are intended to be helpful, mainly, to those cultivators who love chrysanthemums but do not possess pots in which to flower them, nor time to attend to the watering of plants in pots. Each year I generally plant out and lift 1,000 plants, often more. They bear flowers from October to the end of January, under glass. The varieties include October, December and January flowering ones. They should all be planted now. A very rich soil is not necessary nor desirable; it should be of medium quality, so that the shoots will be strong, and short-jointed, not long-jointed and sappy. Having provided a rooting medium of this kind and, in due course, watered when necessary, feeding with liquid manure may be carried out according to the condition of the plants in August and September. Feeding will not be needed at any other time, save in exceptional cases. The stopping of the plants should be done about ten days before, or after, the planting. The last stopping of the shoots should be done not later than the third week in July, or buds lacking petals, normally, may result. As a guide to distance apart to plant, varieties growing 3ft. high should be planted 18ins. apart in the rows, and the latter should be 3ft. asunder. The rows are best running due north and south, to allow the maximum amount of sunshine to ripen the wood. In some quarters where no border is available, ridges of soil 9ins. high and 16ins. wide may be formed and the plants put out in the usual way. Nearly all the soil will adhere to the roots when the plants are lifted and replanted under glass.

STAKING RUNNER BEANS AND TREATMENT OF BUSH-GROWN PLANTS.

Runner beans, unstopped, grow very tall, and to stake them adequately would entail much labour and costly stakes. If the two last-named items are not important, then good staking may be the rule. There are several ways of placing stakes to the plants: in rows, with a stake to each plant; in clumps, with from three to nine stakes to each;



and with strong ordinary pea sticks Some from preference, and others because stakes and sticks are too scarce, stop the plants and so treat them as dwarf bushes. There are many positions in gardens where clumps can be grown both for use and ornament. Such clumps should be, at the base, quite 3ft. in diameter, as shown from *a* to *a* in the sketch, and, at the top, 18ins. across, shown at *b*; a freshly cut stick, bent to form a hoop, will keep the stakes firmly in position, as shown at *c* and *d*. The point of the bush plant is stopped, when 1ft. high, at *e*; resultant side shoots at *f, f, f, f*; later shoots, also, at *g, g, g, g*. This treatment makes the plants grow strongly. Well grown plants bear pods like the one at *h*; badly grown and neglected plants bear ill-shaped pods like the one at *i*.

ST. BRIGID ANEMONES.

These flowers should be grown by all lovers of brightly-coloured blooms and handsome foliage. They are called St. Bridget as well as St. Brigid, the latter being mostly used; it is, I believe, a corruption of the former. It is often claimed for these plants that they will only grow satisfactorily in a light or sandy soil. I have tried them in various kinds, from light to sandy and from gravelly to clayey, and find the best results from a medium, well drained loam. In a sandy soil the foliage is dwarf, in a clayey soil it is medium in height and also the stems, but the flowers are richly coloured. In the medium heavy loam the leaves, their stems and the flowers are equally good. The plants are easily raised from seeds. The work is a very interesting one and, at a small expense, hundreds of plants can be obtained. The seeds may be sown in spring or autumn; those plants resulting from the former will flower the following winter and onwards; those from the latter, the next summer, late, and throughout the autumn and late winter. The seeds resemble cotton or thistledown in its fluffy appearance, and it is well worth while spending a little time separating the seeds before sowing them. Sow thinly and cover lightly, using loam, two-thirds, and leaf-soil, one-third. The rough leaves grow from the stem just below the seed leaves and not from the axils of the latter; the seedlings, even, make many and long roots, so early transplanting, and in a deep soil, is advisable. If a cold frame can be devoted to a batch of plants, a rich harvest of blossom will be available in adverse weather in the winter.

MAKING ARRANGEMENTS FOR SUMMER BEDDING.

After June 1st the work of bedding-out plants will begin, the hardier subjects being planted first, the most tender ones about the middle of that month. In the meantime it will be necessary to think about dealing with the bulbs and other spring-flowering plants that are to be kept through the summer for use again next autumn. A reserve border in the vegetable garden, or in some other quarter, should be dug ready for the spring-flowering subjects to be planted in. Then it will be necessary to consider the condition of the soil; it may need enriching with manure; if so, well rotted manure is the best to use. In some districts such manure is difficult to obtain, then old leaf-soil and decayed garden rubbish, especially that which has been burned in a smother fire, will prove very beneficial to the plants. Such kinds as zonal pelargoniums and petunias should be grown in a medium rich soil to obtain sufficiently strong growth, also plenty of blooms. Fine foliaged plants should have a fairly rich rooting medium. Gold and silver-leaved plants must not be grown in a rich soil, or the variegation will be lessened. Count and allot the plants for each bed before any are planted.

GEORGE GARNER.

CORRESPONDENCE

PLANT HUNTING.

SIR,—As an old hand at the game of plant collecting in Switzerland and elsewhere, I have greatly enjoyed the two recent articles of Mr. Stuart Thompson, whose books I have used on such expeditions since 1912—with these, and Farrer, one can usually know what to expect and what it will look like. Hegi's "Flora des Mittel-Europa," is useful later in deciding the finer points of species differentiation, but too bulky to carry, of course; and Schroeter's "Pflanzen leben der Alpen" (now being republished, and sorely wanting translation), helps to pass the winter months and clear the mind on many subtle points of growth and habit.

Your editorial of May 9th is a useful supplement to these two admirable articles, but there are several points of warning that should still be brought to your readers' notice. Firstly, collecting should be meticulously sparing. I do not think there is any justification for taking plants which can be obtained cheaply and in good condition from many nurserymen in this country (I speak for amateurs), except in cases where outstandingly good forms are found, or unusual colours. It should be remembered that it is most often quite futile to try to extract long tap roots from crevices of the living rock, when a little farther up the slope a possible patch of scree or shale will provide compact rooted seedlings. It is sheer murder to take Viola cenisia, Saxifraga florulenta, Eritrichium nanum and the higher androsaces.

Secondly, the collector should endeavour to keep within the laws of the country where he takes his plants and not outrage local feeling by his depredations. In the Engadine there is a very large list of forbidden plants; in France one cannot use parcel post. Customs officials are often Fascisti. In the Maritime Alps collectors are not, or were not, popular; to quote from Saint Yves' monograph on the distribution of Saxifraga florulenta (Nice, 1907), "A Bavarian nurseryman spent seven weeks in August, 1903, collecting thousands and thousands of roots of the precious saxifrage. . . . Moreover, this is not an isolated fact. In 1897 a collector of Limone was instructed to send to an English firm a thousand bulbs of the very rare Fritillaria Moggridgei and F. tubæformis . . . the Pyrenees have also been the scene of similar devastations. About 1884 an English firm had instructed guides and porters from Gavarnie, to procure the greatest possible number of bulbs of the magnificent Narcissus cernuus Salisb., which grows on Mont Perdu. The number of bulbs sent would have been, apparently 30,000. . . . This odious traffic only came to an end when the Spanish shepherds, jealous of the profit thus made from their territory, welcomed the folk from Gavarnie with gunshot." One does not often meet such a reception; and in many places there are guides who make a point of showing off the local rarities. But for other reasons one has to be careful in wandering about frontier valleys and ridges. One may be taken for a smuggler, or a spy. To quote Ball, speaking of the Tenda district, "Travellers are regarded on both sides of the frontier with the greatest suspicion, and certain passes and summits are absolutely closed to them. . . . Sketching, photographing, taking notes or mapping, as well as any conversation with natives . . . should be most carefully avoided under pain of disagreeable consequences . . . etc." This was pre-war, of course, but how true is it now? We do require trustworthy information on this and local regulations regarding collecting and despatching plants.

Ones difficulties do not cease on reaching England. I am at present conducting an unsatisfactory correspondence with the Ministry of Agriculture over the question whether alpine plants sent from abroad must be accompanied by a certificate of health. Their powers under the Destructive Insects and Pests Order of 1922 are apparently ill-defined and in practice unlimited. The penalty is £10 and confiscation, but penalties are rarely enforced.

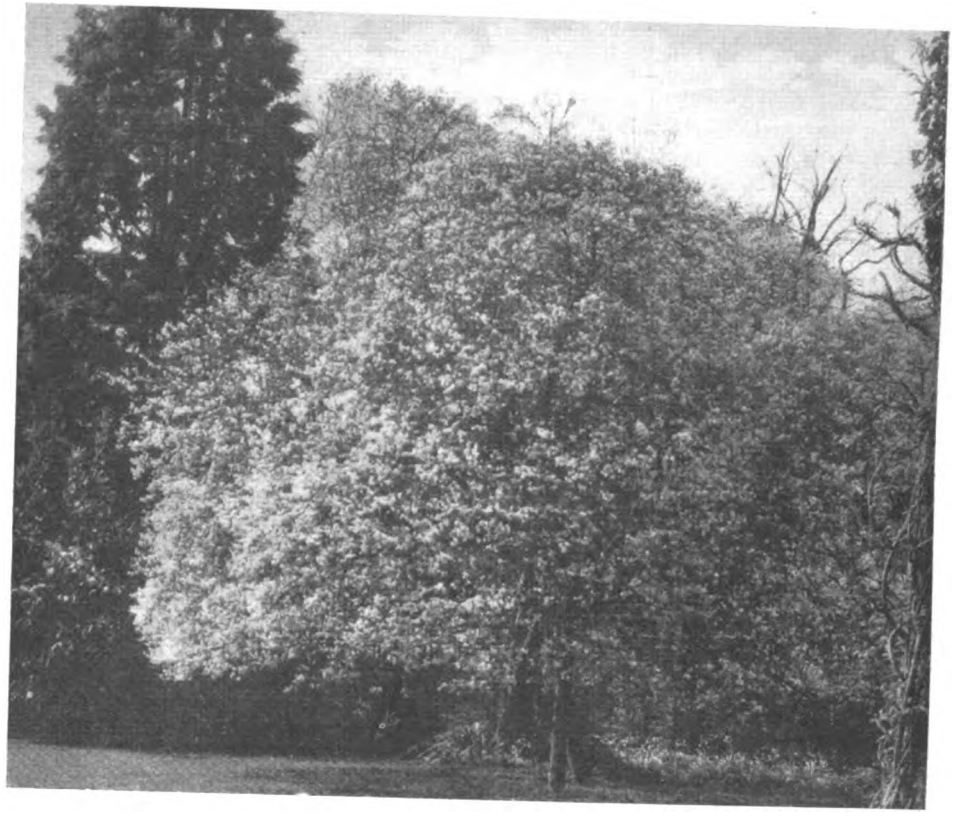
Plants brought back to this country, however packed, must be treated as surgical cases and given careful nursing. My own practice is to have a frame filled to within 2ins. of the glass with sharp sand, in full sun, and to put everything received into this, keeping close and watering frequently, until the chlorophyll comes back to the etiolated leaves and new roots push out. It is vigorous, even brutal, but successful, and the frame can be used without alteration for striking cuttings. Small and well rooted plants, after hardening, go out into the garden; larger clumps are re-divided and kept in cold frames, by way of reserve; for these newcomers sometimes exhaust themselves in their efforts to settle down, and fail to cope with our wet, warm winters. It is always a moot point whether one should leave flowers and seed pods on the collected plants. I think not, though I have, on occasion, saved both mother and child.

As regards apparatus, I prefer a rucksack and I find an ice axe a useful adjunct to the flat trowel—hardened climbers shudder and turn away at the sight of the strange uses it is put to. Numbered tags and a notebook are more practical than writing direct on a label—more room and easier writing.

The list of place names given by Mr. Stuart Thompson omits one little *Paradisus in Sole*, in Les Plans, above Bex (Vaud). Apart from the really exceptionally good alpine garden run by the University of Lausanne, the flora is good; granitic and limestone meet, each with their own typical species, which hybridise in the wildest fashion along the join; Rhododendron hirsutum crossing in infinite gradation of dominance with R. ferrugineum. One valley is yellow with Anemone sulphurea, but cross the ridge and the slopes glisten with A. alpina. High alpines save you the trouble of climbing to see them by growing engagingly in torrent beds thousands of feet below their proper level.—H. T. DENHAM (M.A.), *Wilmslow*.

THE SNOWY MESPILUS.

SIR,—The amelanchier family is a small one consisting of only four species, although the number of names under which it appears in catalogues is legion. The four species are alnifolia, oligocarpa, vulgaris and canadensis. All are natives of Canada or Northern United States, so should be quite hardy in this country, and it is surprising that this ornamental tree should not be more commonly seen than it is at present. Being of moderate size and graceful form, it is suitable even for small gardens where there is no great space for large trees, while the profusion of white blossom in April can be seen in the illustration. Not only is it beautiful in the spring, but also in the autumn it gives an almost more wonderful display owing to the gorgeous colouring of the leaves before they begin to fall. The tree shown in the illustration is in the garden of Sir Benjamin Bromhead at Thurlby Hall, near Lincoln, and is a very old specimen of Amelanchier canadensis, or snowy mespilus as it is generally called. Although it is correct to write "is," perhaps "was" would be a better definition, for, although the tree is still alive and sending out fresh growth from the old stem, unfortunately since this picture was taken storms have played havoc with the boughs and to a large extent have spoilt the central object of this old-world garden corner.—F. H. H.



A FINE OLD SPECIMEN OF THE SNOWY MESPILUS (AMELANCHIER CANADENSIS).

AN INTERESTING DAHLIA.

SIR,—I send details of a dahlia that is in full bloom, thinking it may be of interest to the readers of THE GARDEN. It is of the Yellow Celoise variety, small bulb and grown in a greenhouse at Fingest, Bucks, and the bloom measures 6ins. across and the petals 2ins.—A. E. BOYLES.

DIGGING AND TRENCHING.

SIR,—I would like to be permitted to confirm Mr. Edwin Beckett's advocacy of trenching very clayey soils late in winter rather than in the autumn. I did the latter in dealing with some clayey ground, many years ago, with a view to being up to time with the work. A rainy winter followed, and I had the work to do again; the soil was then a paste early in spring, and it did not "work" kindly throughout the summer. The crops did not thrive, and I learned a valuable lesson. Now, I prefer to form rather high ridges if I am obliged to work such soil in the autumn. A neighbouring farmer experienced the same difficulty. He remarked to me one autumn, "I have ploughed my clayey field; if the weather is dry I am right, if it comes wet I am wrong." It came wet and he found more trouble.—G. G.

VIBURNUM CARLESII.

SIR,—It puzzled me to read in THE GARDEN of May 2nd Mr. Stern's encomium of Viburnum bitchuenense. It must surely have been through a slip of his pen that he extolled it higher than V. Carlesii. I have not his note before me, but since reading it I have examined plants of both species, only to be confirmed in regarding V. Carlesii as the choicest of the deciduous species, and V. bitchuenense as not worth growing at all. Mr. Stern credits the latter with pink flower-buds, whereas I have never seen them as other than white; but in V. Carlesii they contrast beautifully with the snow white expanded blossoms.

Most of the plants of V. Carlesii supplied by nurserymen are grafted on V. lantana. It requires incessant vigilance to prevent shoots from this irrepressible stock overpowering the scion, especially as the foliage of the two species closely resemble each other.—HERBERT MAXWELL, *Monreith*.

THE BALSAM: A PLEA FOR AN OLD FLORISTS FLOWER.

SIR,—Will you allow an admirer of a very charming annual, but one which has long since lost its popularity, to enter a plea for restitution and better recognition of the balsam? It is seldom, indeed, that one now meets with it, and it is no exaggeration to say that by the large majority of gardeners of the present time it is quite unknown. Time was, however, when in most establishments the order for seeds to be sown in spring included a packet of this—when well grown—very pretty flowering plant. I venture to say that one of the reasons why it lost ground was because, unlike so many other subjects, the blossoms were useless for cutting: could only be admired, in fact, and, therefore, in many places, this, one of the oldest of florists' favourites, was dropped. I am sometimes told that it is no use in these days growing flowers that have no value for cutting; but to me, at any rate, this seems an altogether too sweeping assertion. One might as well deprecate the culture of gloxinias, cyclamens, begonias—to name a few—that no one would dream of using as cut flowers, yet would not be without such plants that add beauty to a house. As greenhouse tenants, however, it is seldom that one meets with balsams. Occasionally I have noticed an odd plant or two in some cottager's window—an indication, at any rate, that interest in this annual is not quite extinct. One has a recollection of their being found on exhibition tables in the 'seventies, grown in 8in. pots under generous conditions in regard to compost, which was made up of old loam, leaf-mould and sharp sand, with an addition in the shape of some old cow manure. In a genial temperature balsams were shown with stout stems with plenty of lateral growth full of waxy blossoms, the pride of many an old florist of bygone days. I am not advocating a return to abnormal culture of so pretty an annual by finally shifting plants into pots one is accustomed to see chrysanthemums occupy, but to a revival of interest in a plant which, grown under ordinary conditions found under a greenhouse roof, and bloomed, say, in 5in. pots, merits praise when the beauty stage is reached. It was only a year or two ago that, in passing a house in the windows of which were flowering plants, someone remarked, "Isn't that beautiful?" and, almost in the same breath, "Whatever is it?"..It happened to be a well bloomed specimen balsam which excited my friend's curiosity. It seems to me that we are losing much to-day in allowing its culture to lapse, and I therefore enter a plea to those who have only, maybe, had a negative interest in this delightful annual, to become better acquainted with it.—W. LINDERS LEA.

OBITUARY

RICHARD PINCHES.

WHEN a man who was never a horticulturist and took no pains to conceal the fact becomes an active participant in the most prominent and important movements for horticultural progress, not by reason of his own tactics, but because of the spontaneous and appreciative welcome and urgent request from all quarters, he is, assuredly, a man of no ordinary character, a man whose worth one appreciates but never attempts to estimate.

Richard Pinches was widely known all Britain over, and wherever he was known he was not only esteemed but loved. "Pinches of Acme labels fame" has been a familiar phrase, but it was but a mere tab of identification, for in business life alone he has conferred upon nurserymen, exhibitors and floral artists benefits in a host. A long-felt or a new-found need had only to be explained to Richard Pinches and his fertile brain and mechanical ingenuity were immediately concentrated upon meeting that need, and always with greater concern for the assistance of a friend and the advancement of horticulture than for his own benefit. The graceful and pleasing arrangement of the flowers at Chelsea Show this week is in large part due to equipment conceived and designed by Richard Pinches. Still, the greatness of the man rests even more surely upon his ungrudging services on committees of well nigh all the floral and horticultural societies that meet in London, where his foresight, mental vision and wise counsel have times innumerable helped to achieve successes, and frequently to steer the barque of some society through troubled waters. Beyond and above all this, his personal friendship has been a blessing to a vast number of Fellows who had the good sense to confide in Pinches and seek his advice. Richard Pinches was proud of being a Londoner, but much of his early life was spent in the provinces. His natural endowments were admirably developed by a sound education and early association with men of character and accomplishment. At one time a master at Chester's illustrious School of Art, he later devoted himself to commercial art in Norwich, where he was designer and draughtsman to an important furnishing house.

Edinburgh Royal Botanic Garden Guild.—The members of this Guild have arranged to hold a meeting in the Lecture Hall of the Royal Botanic Garden on May 20th, 1925, at 7 p.m., with the object of reviving the interest in and arranging for the continuance of the Journal of the Guild. Mr. A. McCutcheon, the secretary (pro. tem.), would be pleased if all old members would endeavour to be present. He would also be glad if members of the Guild who have changed their addresses since the publication of the last Journal would let him know their present addresses for inclusion in the next issue of the Journal.

The Iris Society.—In May, 1922, a small gathering of iris enthusiasts met together in London to welcome Mr. J. C. Wister (President American Iris Society), M. S. Mottet and other Continental visitors. At this meeting the idea of a British Iris Society was proposed by Mr. R. W. Wallace, and on October 4th "The Iris Society" came into being. Many interesting papers have been read at the Society's meetings, but apparently these were not published. During 1924 the Society seems to have largely increased, and the first Bulletin is now to hand. This deals chiefly with the cultivation of bearded iris in different parts of the country, and we note articles by some of the leading experts, as Sir Arthur Hort, Mr. W. R. Dykes, Mr. G. Yeld, etc. The Hon. Secretary, 25, Bower Mount Road, Maidstone, informs us that he has a few spare copies of this Bulletin which he will be pleased to send to our readers, gratis, and application should be made direct to him. We hear that Bulletin No. 2 is shortly to be issued, and contains articles of special interest by American and Continental experts. We are glad to note that this Society has realised the urgent necessity of dealing with the classification and nomenclature of iris in commerce, and the first step has been taken towards this somewhat difficult task by co-operation with the Royal Horticultural Society, whose Council have arranged for iris trials to be carried out at Wisley. A joint committee of the two Societies has been set up, and a large number of the leading varieties has already been planted at Wisley. We think that those interested in Irises would do well to get into touch with this useful Society, and we hear that the annual subscription is 10s. 6d.

A Cup for Peonies.—Peonies are so comparatively easily grown that it is a matter of surprise that they are not more largely used in our gardens than appears to be the case. In America their value has been realised for some time, and there seem to be many enthusiasts who cultivate a great number of varieties. Among them the best known is Mrs. Edward Harding, who published in 1917 "The Book of the Peony" and, more recently, in 1923, a smaller volume on "Peonies in the Little Garden." So convinced is Mrs. Harding of the value of peonies for garden decoration that she has presented to the Royal Horticultural Society three cups to be awarded for exhibits of these flowers. The first is offered for competition at the R.H.S. Show on Tuesday, June 9th, 1925, for the best exhibit by an amateur of three flowers each of six varieties of peony. Medals will be awarded as the second and third prizes if the exhibits are considered to deserve them. It is hoped that Mrs. Harding's generous offer will encourage a keen competition among amateur growers of peonies.

Entries should be received by the Secretary of the Royal Horticultural Society, Vincent Square, London, S.W.1, not later than the first post on the morning of Wednesday, June 3rd, and all exhibits must be staged not later than 11 a.m. on the morning of Tuesday, June 9th.

GARDENERS: I—THE COMMUTER

LIVING as I do in London, I count among my friends many who live in the country and work in town. We have no name for this method of life, so I have to borrow an American expression: he who commutes, the commuter. Although he could be called a week-end gardener during the winter months, for he never sees his garden except on Saturday and Sunday, yet the true week-end gardener conjures up the vision of gardening on ground which is not home, but a plaything to be visited on a fine Saturday to Monday in summer. Ergo, the real week-ender, can only play at gardening, whereas, if a commuter takes up gardening seriously, it usually ends in becoming one of the most important things in his life.

There is no gardener so serious as the real commuter gardener, and perhaps this is strange, for he is comparatively a new comer, brought into existence by such modern conveniences as the motor and the electrification of suburban railways, but he has certainly come to stay and will take a greater part each year in our gardening life.

There is an expression that there is no fool like an old fool. Perhaps the metaphor is a little unkind, but there is certainly no gardener so keen as he who takes up horticulture late in life. Presumably he is a busy man and in order to make a living has to train his brain in his occupation, and so, having to fight his own battles in a city, is able to attack the science of horticulture from the right angle, for to be able to weigh the pros and cons is just as great an asset in gardening as in anything else. The commuter gardener may often stumble, he certainly makes mistakes, he frequently scorns the obvious, he sometimes defies old established rules and customs, but some way or other he gets there in the end and accomplishes what he has set out to do.

You can see them at any of the big flower shows, very much the city man, bowler hat, starched collar, short black coat, dark trousers, black boots and all, and you wonder what this incongruous figure is doing. You may watch him and you suddenly discover that he is there with a purpose, that he is not merely there to pass the time of day with his friends and admire the exhibits. He knows what he wants and he has a nose like a truffle-hound for finding good varieties or new species or odds and ends which are not easily found.

This may sound a most unromantic form of gardening, but it is not. The only thing is that romance varies according to conditions. The commuter gardener levels all his affections of the countryside on getting results and he says quite frankly that it is his garden that interests him and not the general panorama. Consequently he often knows more of the lore of his particular branch of gardening than the man who spends his life in the country and whose country pursuits are much wider in their application. The commuter gardener often studies the literature of his subject in the evening; he is always a voracious catalogue reader, while the man who lives in the depth of the country rushes to his wireless or to the latest novel. This criscrossing of ones aspirations is only natural; it is the desire to escape from the rut.

I have a great admiration for the commuter gardener. Invariably he makes up in keenness what he may lack in knowledge or even in judgment. It is obvious that this is so, for there is no necessity for him to garden; if there are not already six tennis courts and a golf course or two in the neighbourhood, there soon will be. One commuter of my acquaintance with a passion for rock gardening started, I confess partly on my advice, growing various species of primulas. He has become keener and keener on the genus and has combed the British Isles and the Continent for treasures. In the space of one short year he has amassed a wonderful assortment. Not content with collecting the plants, an occupation which I am sure has given him a great deal of fun, he has also followed the trail of finding out all he can about them. Everyone knows that as a genus the primula is difficult to grow successfully. Many gardeners would take a good deal for granted with consequent failures. Not so my friend; he takes nothing for granted and no doubt will be extremely successful.

This case is not by any means an exception, for as a rule the commuter gardener is a vigorous individual who knows his own mind and sees that he gets what he wants. I am shown over many gardens in the course of a year and I must confess that almost without exception the best of the smaller type of garden that I see belong to people who journey daily to a town, not necessarily London, to work. There may be something in the old proverb that familiarity breeds contempt, for there certainly seems to me to be a vigour and a freshness in outlook and result when a business man takes up gardening, which is occasionally lacking in gardens where the owner is at hand every day in the year.

PLANTS FOR THE WOODLAND

BY DR. R. LLOYD PRAEGER.

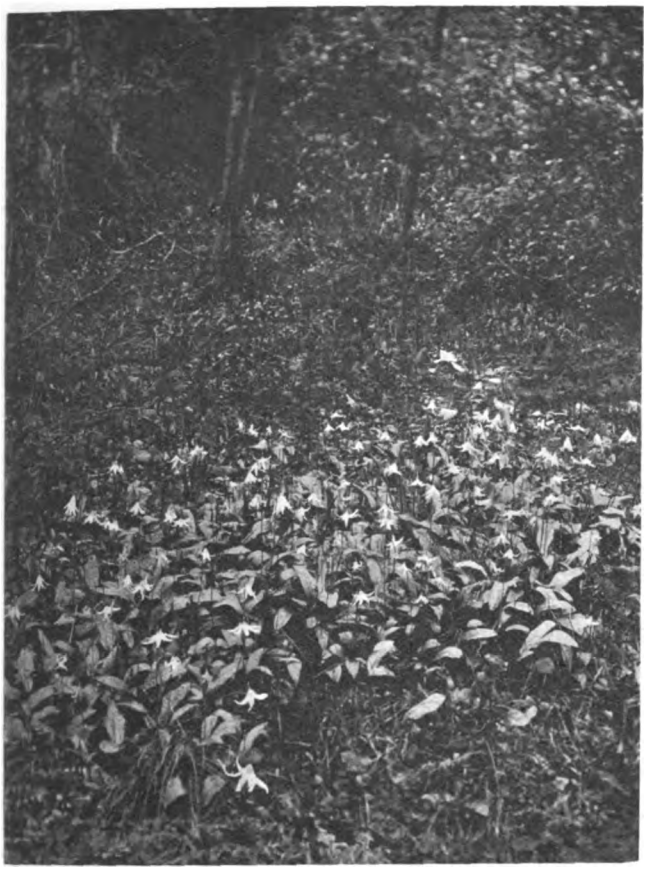
LOOKED at from the gardening point of view—the natural point of view for this journal—the subject of woodland plants resolves itself into the question: What species can we plant under trees with a fair chance of their succeeding? The list is a good deal longer than might at first be supposed, I think for the following reason. In places where summer really *is* summer—in Galicia, Lombardy or Carinthia, Maryland or Manitoba—many plants live in the woods to escape the heat and glare of July and August. But our comparatively cool and watery summer sunlight (cold and wet best describes the sunlight of the past two "summers") is something of which these shade plants are not afraid, and in consequence we are inclined to class as border plants many which are actually fitted to a woodland existence. Woodland plants flourish in partnership with trees by means of various devices, for they live under peculiar conditions. Firstly, there is a great diminution of light. Even in a leafless wood the amount of light which reaches the ground is only about a quarter of that which falls on the tree-tops; when the trees are in leaf the amount of illumination is much less still, depending on the kind of tree. While in a wood of birch or oak sufficient light gets through to allow of a varied ground flora, a forest of beech or spruce may so reduce the illumination that no ordinary plant can live, and the only inhabitants (among the higher plants) are a few parasites or saprophytes which, like toadstools, are not dependent for their food supply on the action of sunlight upon chlorophyll. Then, again, plants growing in woods must guard against drought, both because the trees use up a vast amount of the water of the soil and because the leaves intercept much of the rainfall, and it evaporates without reaching the ground. The scarcity of light and water in summer, then, is the main difficulty that woodland plants have to face. While they meet it in many different ways, two methods stand out conspicuously. In the first place, they speed up when the year begins, and get through their "summer course" early; they do their growing and often their flowering before the trees come into leaf. In this way they get plenty of light and moisture during their active period, and their blossoms are more open to insect visitors, or to the wind in the case of wind-pollinated flowers. Secondly, they very often have swollen underground parts—bulbs or tuberous roots or stems—in which food is retained through the dry season and is held ready for an early start in the following spring. The rich humus soil in which woodland plants live no doubt renders the problem of existence easier, and it has in some cases resulted in the total abandonment of the chlorophyll habit which is characteristic of the whole vegetable world with the exception of the fungi.

But it does not follow from what has been said that we may assume that a spring-flowering species or a bulb-bearing species is therefore a woodland plant. Nature employs these devices in other cases besides. Bulbs, for instance, are abundant on the African veldt, where their use, indeed, is to store up food through the burning summer, but where a high light intensity prevails during the plant's growing period, to which it has become accustomed, and without which it would pine. But where, among hardy plants, we find thickened underground parts, or early flowering, or large, thin leaves, or a partiality for leaf-mould, we may suspect that many of them will not object to woodland conditions. And by this last phrase one implies much more than attempts at planting in actual woodland. Wherever sunlight is cut off for the greater part of the day these observations apply. It may be the north side of a house or a wall or a fence or the shade of a single tree. Anywhere where ferns will flourish, and in some shaded places too dry for ferns, the woodland flora will supply some species to come to the gardener's assistance.

THE HELLEBORES FORM A CHARMING SET OF WOODLAND PLANTS.

But it is time we came on to the plants themselves. Let us take the more obvious spring-flowering herbs first, as exemplified by the celandines and primroses and anemones of our own woods, and consider them in relation to woodland planting. The hepatica (Anemone Hepatica and Hepatica triloba) is characteristic of northern and alpine European woods, and one cannot have too much of it and its allies—white, red and blue, single and double. The hellebores furnish a charming set of winter-flowering shade plants, ½ft. to 3ft. high, with flowers of green or white or purple. The hellebores are so well known that it hardly appears necessary to give a selection of the many species. All are fond of a rich soil, and are very slow and deliberate in settling down to business. Like the foregoing, epimedium is a very early-flowering genus with delightful foliage and graceful sprays of red, yellow or white blossoms. Its cousin Vancouveria is charming likewise, spreading rapidly and flowering later. The type is deciduous, but var. sibirica is evergreen. The lungworts, pulmonaria, are pleasing both from their quaint leaves, often mottled with white, and their flowers, which in most species open red and turn blue, like many other members of the forget-me-not family. There are a number of species, some blooming as early as January. Omphalodes verna, a cousin of the last, is an old favourite, under the name of Blue-eyed Mary, a delightful woodland plant, for though its flowers are not conspicuous, their pure colour is a joy. A large number of other species of omphalodes, mostly very beautiful, have recently come to our gardens. Some of them will probably prove to be at home in the woodland. The forget-me-not family (Boraginaceæ) has still other woodland members, for the alkanet, Anchusa sempervirens, with its leafy stems and intensely blue specks of flower, belongs here, and also Trachystemon orientale, a tall, coarse thing, but fine for a waste place on account of its very early panicles of quaint blue-purple flowers. The buttercup family offers us many very valuable woodland plants in addition to hepaticas. There are all the varieties of anemone

Digitized by Google



ERYTHRONIUMS, THE DOG'S-TOOTH VIOLETS.

of the nemorosa group—nemorosa itself, our wood anemone, with its many beautiful varieties—white, reddish and blue; A. blanda and A. appenina, both lovely blue-flowered things; and the striking A. blanda var. Scythinica, blue outside and white within; the little twin-flowered yellow A. ranunculoides. Then there is the taller A. sylvestris with its large, single creamy fragrant blossoms, and the dainty A. narcissiflora with fan-shaped leaves and many-flowered erect stems. The globe flowers (trollius) and the columbines (aquilegia) are all lovely, and include plenty of shade-loving plants. Then primula is a host in itself. For places of normal moisture we have all the varieties of the primrose, from white to blue, and all the polyanthus forms, and the favourite P. Juliæ, etc. For moister places many of the great crowd of species now found in gardens have no objection to shade, but I cannot from experience indicate which are best in this respect.

I am rapidly exhausting the space at my disposal, yet only now come to two groups of plants which are among the most interesting and characteristic of those which we associate with shade culture—the one a small group of leathery-leaved things, mostly beautiful in flower and often difficult of cultivation; the other the large group of bulbous and tuberous-rooted plants, mainly monocotyledons, that are being used more and more for naturalising under trees.

In the first category come those elegant and distressing plants the pyrolas or winter greens, none really easy, and the most beautiful of all, the fragrant P. uniflora, almost impossible. The difficulty with the pyrolas, as with several others of the plants to be mentioned immediately, is to secure properly rooted pieces. In nature they straggle along, their slender stems half above and half below the ground, rooting only in the most tentative fashion; and when transplanted they linger for a long time, but finally decide to die. The one that I found easiest was P. rotundifolia var. arenaria, from the sand dunes near Southport, where, I believe, it still lingers in spite of the relentless encroachment of golf greens and bungalows. Then there is the attractive American Shortia galacifolia and the even better S. uniflora from Japan: lovely things, if only one can persuade their elusive roots to do their duty. Galax aphylla, also American, is easier than shortia, and its slender spires of small flowers are very dainty. The creeping Tanakæa radicans is graceful and easy, making a mat of low evergreen toothed leaves and runners with sprays of graceful white blossom. Like so many dainty things, it comes from Japan. One must not omit two most fairy-like tiny creeping things—the well known Maianthemum bifolium, which ramps about with its slender twin heart-shaped leaves and plume of white bloom; and the less common Trientalis europæa, a fragile but quite easy beauty, with appealing tiny white stars and delicate foliage. Of stronger creeping things we have the ever-welcome lily of the valley, Convallaria majalis, with its large form and its rosy flowered variant, and a variety of Solomon's seal, polygonatum, all highly decorative. Allied to these is the strange Paris quadrifolia, with its single yellowish flower rising from four leaves set like those of the wood anemone.

What are we to say of all the trilliums and erythroniums and dodecatheons and cypripediums? There are at least a dozen of each which deserve separate mention, for all are beautiful and of high value to the gardener. All love a deep, cool woodland soil, and once established are among the best delights of spring. But space forbids the adequate singing of their praises or displaying of their varied charms. They would need a long article to themselves. Indeed, the same applies to the many bulbs that can be so charmingly used in woodland gardening—galanthus and narcissus especially in great variety, scillas, leucojums and what not and to start into them at this time of day would be futile.

Every plant hitherto mentioned is of perennial duration, and, indeed, annuals or biennials are rare in natural woodlands, and generally unsuited for introduction therein. But there is one glorious genus, mostly biennial, which is so beautiful in leaf and flower, and so varied, that it cannot be passed by, as many of its members are at home in a well drained forest soil. I refer, of course, to meconopsis. While many of the loveliest of the species are rather delicate and miffy little ladies, the stronger or better proved kinds, like M. aculeata, M. integrifolia, M. paniculata and M. Wallichii, are easily raised and easily grown, and have the distinguished beauty of their genus.

THE ATTRACTIVE SHORTIA GALACIFOLIA FROM AMERICA.

THE HARDY BROOMS

DURING the last twenty-five years very important developments have taken place among several species of cytisus, until to-day they rank among the most showy and useful shrubs for sunny borders. Their marked improvement may be attributed to three main causes: (1) natural or chance hybrids; (2) artificial pollination; and (3) selection and raising of seedlings.

For light, well drained soils in sunny positions, brooms should be much more widely planted. They are particularly useful for banks and shrubbery borders which are in full sun. Quite ordinary soil of a light character is preferable to a rich loam in which the plants may make abundant growth but do not flower nearly so freely.

Allowed to grow naturally, the tall-growing kinds soon become leggy. To counteract this, the shoots of the young plants should be cut back several times in the early years of growth; while older plants benefit by shortening the main branches each year immediately after flowering.

Seeds, cuttings and, in a few instances, grafting with the laburnum as a stock provide ready means of increasing broom in quantity.

VARIETIES OF THE COMMON BROOM.

The rich yellow blossoms of the common wild broom, Cytisus scoparius, should be made much more use of by planters in our pleasure grounds, wild garden and open woodland, where not naturally wild. It not infrequently happens, when a few seedlings are planted in shrubbery borders and the wild garden, that seeds from these drop in favourable positions for germination and become established without the help of man.

Probably because a native British shrub, the common broom has not received the attention in most gardens undoubtedly it deserves, the discovery in Normandy about 1884 by the French landscape gardener, M. Edouard André, of a wild seedling broom with brownish crimson wing petals and named var. Andreanus, may have appeared to many people a small matter at the time. This departure from the type, however, has proved to be but the beginning of a most important and valuable addition to our hardy-flowering shrubs. As so often happens, once a plant varies from the type, remarkable and much wider variation rapidly follows.

The name of the late Mr. Tom Smith of Newry will always be associated with the early development of the first coloured variations from André's broom. Five distinct named varieties were distributed from the Daisy Hill Nurseries: Butterfly, bronzy red and yellow; Daisy Hill, creamy yellow and deep red; Firefly, the richest coloured form of Andreanus; Mayfly, red and yellow; and Newry Seedling, pale cream with rosy red blotch. Still further developments appear in the following named sorts: Daisy Hill splendens, pale yellow with rosy crimson keel; Dragonfly, golden yellow and rich crimson; Fairy, cream tinged rosy pink; fulgens, orange yellow, dark crimson keel; and Rosy Moonlight, cream tinged with rose.

To reproduce these beautiful varieties true they should be propagated by cuttings or grafted on seedling laburnums

A FINE PLANT OF CYTISUS KEWENSIS.

Seedlings raised from C. Andreanus and the varieties show a very wide variation in colour; while there is always the possibility of a small percentage showing some improvement on the parent, the larger number are usually inferior in colour.

Quite a considerable number of other variations of the common broom are cultivated in our gardens. Newry Gold is one with rich yellow blossoms; sulphureus or pallidus, the Moonlight Broom, though not common, is an old variety (being described by Louden eighty years ago), with pale yellow blossoms which provide a pleasant contrast to others richer in colour. The drooping or spreading broom, var. pendulus, is valuable for banks and for sprawling over boulders and ledges in the rock garden. The name prostratus is frequently used for these brooms in nurseries, but the true variety prostrata is much more close-growing and compact in habit. Of this I have only seen a form with yellow blossoms.

Cornish Cream is a new variety raised at Lanarth, Cornwall, by Mr. P. D. Williams. There are two shades of colour in the flower, the keel being several shades darker than the cream-coloured standards.

The Warminster Broom, C. præcox, a hybrid between C. purgans and albus, originated among a batch of seedling C. purgans in the nursery of Messrs. Wheeler of Warminster in the sixties of last century. It has sulphur-yellow blossoms produced in profusion at the end of April and during the first half of May. Effective in masses in the pleasure grounds, the Warminster Broom should not be planted in any appreciable numbers near the house because of the uninviting odour of the flowers. This broom increases readily from cuttings.

The white Portugal or Spanish Broom, C. albus, is a tall-growing shrub of graceful habit, readily raised from seeds, and the seedlings show some variation in habit and size of the flowers. The best can be selected and propagated by cuttings. The variety incarnatus or roseus has a tint of rose in the flowers and is especially noticeable when half expanded.

The beautiful hybrid broom raised at Kew in 1900, C. Dallimorei, is said to be the first hybrid broom raised by artificial crossing. As the pollination was carried out under glass (C. scoparius var. Andreanus × C. albus), there can be no doubt of its origin, otherwise C. purpureus might be suggested as a more probable parent at first sight, as the flowers are a shade of rosy purple deepening to velvety crimson on the wing petals.

The parentage of C. Dallimorei is soon disclosed when seedlings are raised, as innumerable colours, ranging from pure white, through cream, yellow, forms of Andreanus and colours even richer than typical C. Dallimorei make their appearance.

Apparently the two new varieties, Donard Seedling and Dorothy Walpole, have the same parents as C. Dallimorei, or are selected seedlings from it. Donard Seedling has reddish crimson flowers suffused with a greyish cream, yellow and rose. In Dorothy Walpole the keel is rich rosy purple, with the wings a deep velvety crimson.

C. Osbornii is a very distinct seedling from Dallimore's Broom, raised at Kew, with pale yellow flowers and suggests C. præcox, but is a little later in flowering. The

Digitized by Google

plants are rather more upright in growth, and in the bud stage the colour is deeper. An important consideration is that the odour of C. præcox, so offensive to many, is absent in this new variety.

Two late-flowering cytisuses are deserving of more attention from planters. C. sessilifolius is a native of southern Europe and northern Africa. Though first introduced about three hundred years ago and figured in an early number of the *Botanical Magazine*, tab. 255, the sessile-leaved broom is comparatively little known. It is a bushy shrub and averages about 5ft. in height, with rich yellow blossoms four to eight or ten together, borne in short racemes terminating new side growth on the main branches.

Cytisus nigricans, the so-called black broom, because the blooms turn black when dried, flowers freely during July and August. It is a native of central and south-eastern Europe, and was first introduced in 1730. Growing 4ft. to 5ft. or more in height, the yellow flowers are freely carried in slender racemes terminating the shoots of the year. If the plants are pruned fairly hard each year in February or early March it considerably increases the vigour and length of the flowering shoots.

When visiting the Newry nursery in August, 1915, I noticed seedling forms of the common broom, C. scoparius, still flowering. By selecting the latest to bloom a race of July and August flowering varieties had been obtained. Most of the bushes had yellow flowers, though several with the crimson stain of Andreanus were noticeable. Seeds and plants have been disseminated to customers from Newry, but no doubt largely because of the war they are not much known.

DWARF BROOMS.

For the rock garden and grouping along the front of sunny borders, several dwarf cytisuses are of outstanding merit. C. Ardoinii, with yellow flowers, is free in growth and also very ornamental. It is notable as the parent of two dwarf hybrid brooms: C. kewensis (C. Ardoinii × albus), of spreading habit and creamy white blossoms; and C. Beanii (C. Ardoinii × purgans), of spreading growth, with rich yellow flowers.

The purple broom, C. purpureus, is represented by the type with rosy purple blossoms and at least three distinct varieties—albus, incarnatus and versicolor. A. OSBORN.

C. ALBUS, TALL GROWING AND OF GRACEFUL HABIT.

JOHN RICHARD ANDERSON, J.P.

HIS GARDEN DIARY, 1745. A NOTE BY THE HAND OF DION CLAYTON CALTHROP.

(*Continued from page* 286.)

MY friend does not merely dream his life away among his books or under his favourite tree, but endeavours to keep company with all manner of men whose conversation is not purely frivolous. He has as good a sense of humour as any man and can tell a story against himself with relish.

Among his notes he places anything curious that he hears or that comes under his immediate notice. For example, I find that he is at pains to discover the origin of the names given to flowers both wild and cultivated. "Some names," he writes, "seem to spring from no recognizable source yet they obtain up & down the countryside where a man will speak of the plant 'Good King Henry' not knowing it to be called also 'English Mercury.' Which King Henry can he mean?"

Of "Monk's Rhubarb" (Rumea Patientia) he can see clearly that it is a medicinal plant and comes under the order of Simples (which he often spells "ffimples") such as were collected and cultivated in those days when a knowledge of herbs was a necessary precaution in life. With these so-called pot herbs comes also Herb Patience.

In his day there were many wise women who brewed concoctions against all manner of evils and also as love potions. In the notes especially on herbs one finds names which at one suggest fragrance of both history and poetry.

"Sweet Marjoram," he writes, "what fragrant thoughts arise at the sound of such names as these. 'Herb Teucer,' 'Germander,' 'Wound Wort,' 'Wild Thyme' and 'Penny-royal' and 'Meadow Sage.' In the twilight of Botany such names arose and bloomed through the night of the Dark Ages until the day broke, but in those mists a country Poet sang of simple things near to the Earth as Adam."

Did (this for a fancy) the Herb Twopence gain its name from the first financier and did that careful man give it its Latin name in order to hide the secret of his wealth from the ever greedy: "Lysimachia nummularia"?

Our country poet finds names in this green island awaiting him, to nameless plants and flowers he gives names by a god-fatherdom of his own, and as I read Mr. Anderson I see how justly he sets down not only the learned names but the little names, the first love names. But, mark you, he has method too.

March 1st. Now the Windes come fiercely bind your weakest Plants against they become prostrate. Now is the Time to sow Pinks and Sweet Williams and Carnations. Acquaint your Greenhouse and Conservatory gradually with the Air by Day but trust not the Night. Beware the sudden darking of the Sun and also the Frosts and sharp Winds. If the season be dry water your Anemony roots well once or twice a week. Be careful also that the East Winds do not prejudice your choicest plants, as Tulips and Jacynths but shelter them with Mats.

In April Mr. Anderson's advice is:

that you do now sow Hyssop, Basile, Thyme and Scurvey Grass. Entertain such Exotic plants as you may possess in fresh hot beds with the Art to preserve them and foster them during this Season.

It is now the time of Laycock, White Thorn, Musk, Florence Iris, Lady's Smock and White Violets.

This is the Time to distil Plants for Waters.

Set your Bees at Liberty but expect Swarms.

Note: Some say Gilly-flowers should be planted by Full Moon, but such sayings creep in from one knows not where. Though they be Heathen still the Heathen kept flowers and knew of many strange Devices.

Digitized by Google

For May Mr. Anderson notes that "Snails should be gathered after Rain. Set also tempting baits against the ravages of Insects. Now are flowering both white and blue Campanulas, as is also the Deptford Pink and Homer's Moly with many other flowers too numerous to set down."

He has his Duke, Flanders and Heart cherries, black, white and red, also the Luke-ward and Naples cherries, and at this time he has strawberries, corinths and melons.

In June he notes that "Aviary birds grow sick of their feathers so that he makes Emulsions for them of Melon and Cucumber seeds, and gives them Groundsel, and Chickweed &, if he has some, of the Pome-Granade seeds."

So placid a man as Mr. Anderson has a temper besides for the follies of the people who will not provide for themselves. "There are people in this world," he writes, "who have no thought for the Winter. They never dry a herb or pickle onions or the seeds of the Nasturtium, nor will they keep a Tub of Brine and lay by such pieces of Pig as the Ears, Tail, etc., which would serve them for the winter months. So I must ask my neighbours for old Cloakes & cast away shoes & many other things as old Linen, Medicines & Stale Bread. Mr. Endover doth give me wood for the cutting but Lord these fanglish people as soon cut themselves as wood and a man will as soon drink Gin and other Strong Waters and Smoak his pipe as tend his piece of garden."

Then follows, without due sequence of idea, a note: "The Bill of a Property Man to a Theatre. (Lord how strange to see how effects are come by.)."

	£	s.	d.
For Hire of Six Case of Pistols		4	0
A Drum for Mrs. Bignall in the Pilgrim		4	4
A Truss of Straw for the Madmen			8
Pomatum and Vermilion to Grease the Face of the Stuttering Cook			8
For Boarding a Setting Dog Two Day to follow Mr. Johnson in Epsom-Wells			6
For Blood in Macbeth			3
Raisins and Almonds for a Witches Banquet			8

In July he is at the perpetual war gardeners wage against insects. He straightens the entrance to his bee hives and sets about killing drones. Then he sets glasses of beer mingled with honey to entice wasps and flies, and he hangs these bottles near his nectarines and other tempting fruits. "Else many times they invade your best Fruit." He seeks diligently for snails under the leaves of his mural trees and makes a decoction of tobacco refuse, brine, potash and water with which to water his gravel walks so as to destroy worms and weeds.

In August he makes his cider and perry, keeping his choice apples, such as the Ladies' Longing, Sheeps-snout and Cushion apples for the table. At Bartholemew-tide Mr. Anderson removes and lays his perennial greens, his jasmines and oleanders and translates them to moist and shaded ground.

With all these garden cares and delights Mr. Anderson is happy, but naturally he is not free from the ills the flesh is heir to. There are boys who break in and steal his choice fruit, there is swine fever in the neighbourhood, his favourite horse goes lame and himself suffers from a twinge of "that plaguey thing, the gout." He notes that "cats will eat & destroy your Marum Syriac if they can come at it." And that robbing insects and wasps must continually be destroyed.

"Last week," he writes, "comes Sir Abel Rawley out of the Town and brings me news of the Great World, but O how stale and unprofitable it is and sounds so in my quiet & peace. That Brocade Sword Knots be now worn, that Bat Pigeon is the only wigmaker of elegance; that Lady ——, hath an affair with a low ill bred fellow: and how some madman preaches that a Plague will fall on the Earth by Christmas and utterly destroy all who go to Playhouses & Taverns, these things vex the ear and are vain & small in the country."

Now the good man is at seeing the autumn leaves are swept and gathered together to make good mould; he is taking care that his carnations do not get too wet and so rot. He is preparing against wind and frost, rolling his grass walks and finishing his last weeding.

Now Mr. Anderson prepares for the end of the year, cutting logs for his hearth, trenching his ground and digging in manure. He covers up his bees and turns the fruit in the store room lest it taint. His fruit trees are pruned and nailed to the walls and all in the garden is in order. The fountain pipes are covered with straw against the frost and the conservatory doors are looked to to see that they shut out the cold air.

Here is the last entry in this diary:

Dec. 31st. I do thank God for all His Goodness and Mercy to me in this year, guarding me from loss and from illness of any grave order. I thank Him for the abundant yield of Fruit and Flowers which are a solace to the mind causing man to live simple and in great content.

All flesh is grass. J. R. A.

APHIDES OR PLANT-LICE

TO both farmer and gardener "blight" is a familiar word. It is well known that it is caused by a host of minute creatures which bear the scientific name of aphides. The term "green fly" is commonly applied to these insects—which include the green rose aphis, the woolly blight of apple and pear trees, the hop louse and the Phylloxera vastratrix (the vine aphis), which has at times caused such terrible losses to the vine industry in France.

Altogether there are some two hundred different species of aphides and (though often called "green fly") they vary much in colour. Those found on rose trees are certainly green, but those on beans are black. Others are brown and some are brilliant red.

The extraordinary life-history of these creatures may be of interest to readers. In the spring, female aphides hatch out of eggs laid during the previous autumn. These are

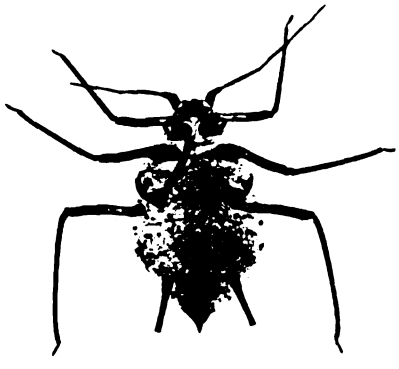

FIG. 1.—THE THISTLE APHIS.

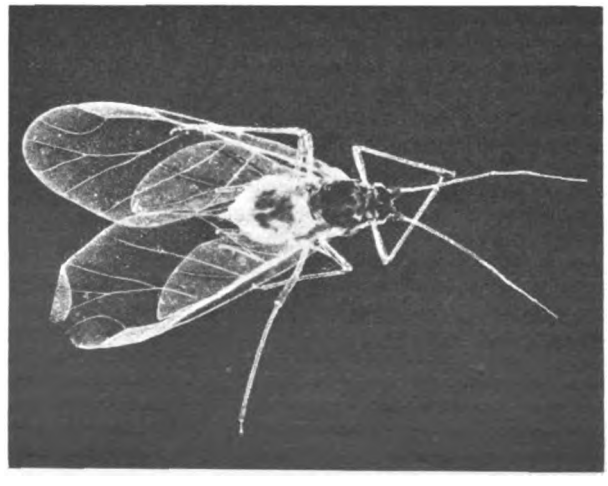

FIG. 2.—THE WINGED APHIS.

FIG. 3.—THE ANT

Digitized by Google

females without wings. They soon grow to maturity and give birth, not to eggs, but to females like themselves. The little ones soon grow up and begin to produce others, and so the process goes on for several generations. Then a strange thing happens. A generation appears which consists of winged aphides (Fig. 2). The wingless aphis is a slow-moving creature and only crawls leisurely over the leaves, but the winged aphis can fly away in search of richer food. It has been noticed that directly a winged generation appears that these will migrate to another feeding ground. The aphis found on apple, for example, produces a winged generation which migrates to the stem of corn and then they produce another which lives on this particular form of food.

Towards autumn a small race appears which consists of males and females. These pair and eventually the females lay eggs which hatch out the following spring, and so the wonderful process of reproduction is repeated year by year.

The extraordinary prolificacy of these creatures accounts for the myriads which exist. Huxley has stated that a single aphis would produce in ten generations descendants (if they all survived) which would "contain more ponderous substance than five hundred millions of stout men; that is more than the whole population of China." Fortunately for us, the aphides have many enemies. Among them the ladybirds, which practically live on them. Bonnet, the famous naturalist, said that as we sow grain for our benefit, "Nature has sown aphides for the multitude of insects." Looked at from another point of view, were there no enemies of the aphides, then men would have little food and would gradually be exterminated by "blight."

Ants (see Fig. 3), which are perhaps the most intelligent of all insects, make use of aphides for their own benefit. They actually "keep" them as we keep cows. The aphides produce a substance known as honey-dew, a favourite food of many insects. Fig. 1 is a photomicrograph of a thistle aphis much magnified. A peculiar structure will be noticed in the pair of syphons at the lower part of the insect. These were at one time thought to be the organs which produced the honey-dew. But this is not true. They are wax-producing organs, and from them comes a substance similar to that made by the honey bee. The honey-dew is formed in the alimentary canal of the insect.

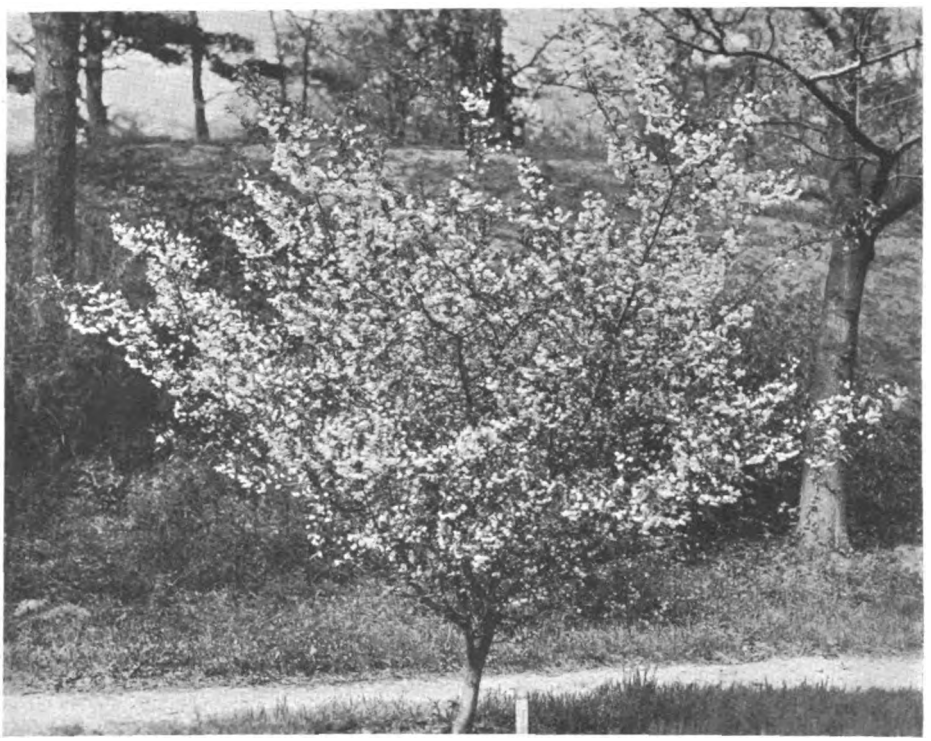
G. H. HEWISON.

A FINE CRAB APPLE, MALUS HALLIANA PARKMANII

THE Arnold Arboretum at Boston is famous for its large collection of crab apples. Especially when the Chino-Japanese species and forms are in flower they are quite a sight. Among the double-flowered forms there is none that can be compared with the variety Parkmanii of Hall's apple. This is the true Kaido of the Japanese.

Before it came to Europe it had been sent to America, where it flowered first in the garden of Francis Parkman near Boston. The type, too, of M. Halliana came first to America in 1863 by G. R. Hall, after whom it has been named. Its origin had been doubtful for quite a time, until it was found by E. H. Wilson in a wild state in western Szechuan, near Tachien-lu. When I was dealing with the genus for my illustrated handbook in 1906, I saw a specimen collected by Fortune at an unknown locality in China that had been referred by Hemsley to M. spectabilis. I stated that it probably belonged to M. Halliana. In foliage and flowers this species certainly much resembles M. spectabilis, which has not yet been collected in a wild state, but is said to come from northern China. It has been known in Europe since 1780, but is unknown even as a cultivated plant in Japan. M. spectabilis has much larger fruits, with a persistent calyx which is deciduous in M. Halliana. The nearest ally to it is M. theifera, a very handsome apple, widely distributed in the mountain regions of western China into Assam. When in flower it looks more like a cherry than an apple, and it is of great horticultural value. Its flowers are, however, pure white, while in M. Halliana the rose coloured flowers are much more conspicuous. Of the variety Parkmanii the colour of the flowers almost equals that of a peach. The fruits of M. Halliana, as well as of M. spectabilis and M. theifera, are of no beauty. Of M. Halliana the fruits have the size of a large pea, they ripen very late in the fall and become brownish red. The illustration shows a flowering plant in the Arnold Arboretum in May, 1916.

CAMILLO SCHNEIDER.



ONE OF THE BEST DOUBLE FLOWERED JAPANESE CRABS.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. 2.

MORE ABOUT THE CHELSEA SHOW

SWEET PEAS

Growers of sweet peas under glass had many anxious moments before the Show, but the welcome change in the weather set their minds at rest, and they were able to display most beautiful spikes of bloom. With their magnificent arrangement of general greenhouse annuals, Messrs. Carter and Co. had many splendidly grown spikes, which were noteworthy for the length of stem, as well as for the size and brilliance of mass colours. Besides a wide range of the standard varieties, which are well known to all sweet pea lovers, they had some excellent new sorts. Ruffles, lovely rosy lavender of large size; Mrs. H. Byford, glowing with fascinating shades of pink; Beacon (its orange colour lit up the collection splendidly); Purple Beauty, well named; Queen Marie, a valuable bicolor with an orange standard and crimson lake wings; Mrs. A. Searles, bright cerise; Enid, pale cream; Superb, of Picture type and rich pink flushing; Geisha, old ivory colour delicately flushed with the palest pink; and Raynes Park, silvery lavender, are the names of most of their novelties of decided merit.

Novelty sweet peas were also freely shown by Messrs. Robert Bolton and Son, and chief among them was the wonderful silvery lavender Wembley, which was the silver medal variety at the trials of the National Sweet Pea Society last summer. Royal Pink is a rich glowing flower, reminiscent in type of that ever popular variety, Picture; Black Bess is the nearest approach to a black sweet pea that has yet been seen—smoky maroon is, perhaps, the best description of its colour. Ivory Picture, which won a certificate of merit last year at the trials was shown in even greater beauty than at the Syon House gardens. Besides these splendid new sorts, Messrs. Bolton and Sons had an extensive collection of the older sorts, such as Picture, Mrs. Arnold Hitchcock, R. F. Felton, Powerscourt, Wizard, and all were of the same high quality and arranged with great taste.

A skilful arrangement was also shown in the very extensive collection of Messrs. Dobbie and Co., where many lovely new sweet peas were to be seen. Magnet is a fascinating salmon pink; Ruby well describes the colour of this rich variety; Mermaid is of lavender tone; while Royal Sovereign, one of the best of orange coloured sweet peas, provided a mass of glowing colour. Then there were three sorts which are probably the best trio ever raised abroad. These are Sylvia and Miss California, of most fascinating pink shades, and both received awards at last year's trials. The third is Youth, a chaste and lovely picotee-edged flower. Of the older sorts space will permit mention of only Constance Hinton, the best of whites; Majestic, cream; and Grenadier, a glorious scarlet. One of the very best of their large vases is as yet unnamed, and is known as Lavender No. 100, a most lovely flower.

Novelties in sweet peas were also freely shown by Messrs. Alex. Dickson and Sons.

MESSRS. BOLTON AND SONS EXTENSIVE COLLECTION OF SWEET PEAS.

Mermaid, pale lavender; Magnet, vivid pink shaded with salmon; Crusader, orange pink; Dainty Maiden, a large flower of blush pink colouring; and Stella, a magnificent cream picotee with a definite rosy margin, were the names of the most striking. Among the standard sorts worthy of mention were Faerie Queen, Purple Perfection, Hawlmark Pink, and the lavender Powerscourt. Besides these and many more, they had vases of four seedlings of considerable merit.

TULIPS

There were quite a large number of tulips exhibited this year, and when the weather conditions before the Show are taken into consideration, it was a pleasant surprise to see such good collections. Many of the same varieties were shown by each exhibitor. At the beginning of the Show the tulips looked in perfect condition, but very soon they opened too widely and began to bend over, so that their true shape and form could not be fully appreciated. The increasing popularity of the Parrot tulip was clearly shown by the number of this type exhibited. They are very effective, but the selfs are hard to beat, especially massed in beds or borders.

Messrs. Dobbie and Co. had a splendid collection of tulips, varieties of Cottage, Darwin and Parrot tulips were chosen. Dido was a large, handsome flower, orange-red in colour and edged with yellow. King George was a good carmine-red Darwin tulip and Swanenburg (white), Harry Veitch (a deep crimson), Farncombe Sanders (scarlet), Euterpe (mauve), Isis (brilliant crimson), Violet King, Julie Vinot (a soft rosy-pink), and International (purple), were others belonging to the Darwin class. Cottage tulips, too, were well represented, and among them were some very fine colours, with the exception of some of the bronzy and bluish-mauve tulips, which are not considered beautiful by the majority of gardeners. Walter T. Ware was a lovely golden yellow Cottage tulip, Zany, an effective striped crimson, The President a rich orange, and at the back of the stand the Parrot tulip Markgraaf made a striking effect, with its wide open yellow petals striped with red.

An even larger exhibit of tulips of every class was staged by Messrs. Barr and Sons. The varieties they were showing were particularly interesting. A strange coloured tulip was Viridiflora, with its green and yellow petals. Quaintness was another distinct variety. Loveliness, a rosy pink; Isis, a brilliant crimson, shaded blue at the base; and Salmon King, were some of the Darwins shown. Ronald Gunn is a poor coloured tulip and is not effective. Mrs. Kerrel was a pretty shaded rose and amber Cottage tulip. Some of the yellows and oranges were exceptionally fine on this exhibit. Mrs. Hoog was a beautiful clear, light yellow. Gesneriana lutea and Inglescombe Yellow, two deeper yellows, stood out against the glowing red of Feu Brilliant and the deep shades of Zulu.

Groups of Petrus Hondius, Isis, Professor Rawenhoff and Mr. Farncombe Sanders, made vivid patches of colour among the tulips exhibited by Messrs. R. H. Bath. Countless varieties were shown by this firm, and the flowers were large and of good shape. Zomershoon was an attractive white and red variety; John Ruskin, a large apricot flower, and Faerie Queen, a mauve with yellow edged petals, together with Moonlight, Perfecta, Scarlet Perfection and Opal were a few of the best.

The Maytham Gardens selected a few of the self-coloured tulips to form their exhibit. In many ways the individual varieties can be better appreciated by this arrangement, but it does not cater for the varied tastes of the general public. Ellen Willmott, a clear primrose yellow; Mrs. Potter Palmer, purplish crimson; King Harold, blood red; La Tulip Noire; and Faust, both very dark, together with Orange Perfection and Chestnut, were some of the best varieties in this group.

Tulips from the Welsh Bulb Fields were staged by Mr. W. A. Watts. Several varieties which were seen on this stand were exhibited by no other firm. Panorama, a rich chestnut red Breeder; Tak Van Poortvliet, a dark red; Gustav Doré, a pale rose Darwin; Solomon, a mauve Cottage; Ida Scott, a deep mauve Darwin; and Marcella, a bright reddish maroon, were typical of the varieties exhibited. Neither Corydon nor Crepuscule were good colours, but the soft shades of Amber and Psyche are suitable for massing with some of the deeper tints.

Digitized by Google

Mr. J. Pearson had a good stand of tulips, and among them Inglescombe Pink, Feu Brilliant, Farcombe Sanders and Andromache, were very effective. Frans Hals, clear violet; Orange King; Velvet King, a shining velvety purple, with a clear yellow base; Retroflexa superba and Marconi, were a few of the best.

Several fine varieties were shown by Mr. Ernest Paul, and among them Yellow Picotee, Yolande, Honeymoon, Prince of Wales, the bronze orange La Merveille, the soft apricot Darwin Afterglow, Roi Soleil and Wilberforce.

Some of the tulips of Messrs. Toogood and Sons, Limited, were very good in form, and the flowers were borne on long strong stems. Parisian Yellow, one of the tallest yellow May-flowering tulips; William Pitt, a glowing deep scarlet Darwin with a blue and white base; Princess Elizabeth, a vivid rose Darwin; and Europe, a scarlet Darwin shaded rose and with a pure white centre, were the most noticeable varieties.

The only ground group of tulips was staged by Mr. Herbert G. Longford. Blocks of separate varieties were bedded in moss; the exhibit could have been more effective if brighter and better coloured varieties had been selected. Some of those chosen were Nora Ware, a silvery lilac; Bronze Queen, a bronzy orange; Moonlight, a large primrose yellow flower; Bartigon, a carmine crimson, edged with purple; and William Copeland, a mauve shaded Darwin.

THE MAGNIFICENT GROUP OF TULIPS STAGED BY MESSRS. DOBBIE AND CO.

HARDY PRIMULAS

Of late years, there is no genus of plants save rhododendron which has come so much before the public eye as the primula. From a mere handful of species twenty years ago, the number has gradually increased year by year until now they run into hundreds. China—that wonderland of trees and flowers—has supplied the majority of these, and the horticultural public owe a debt of gratitude to those amateurs, and no less to the collectors, whose enthusiasm and keenness have resulted in such a wealth of brilliant species and forms of this ideal rock garden and woodland denizen. From the cliffs and woodland glades of China is a far cry to these islands, yet, notwithstanding their new climatic conditions, the plants staged at Chelsea would do fair to rival their Chinese relations.

That a boom in primulas has arrived was very evident by the large numbers which were staged by many firms in their rock garden exhibits and also by others, such as Dr. Macwatt, who made them their sole attraction.

In the trade groups the most interesting was that of Messrs. Oliver and Hunter, Moniaive, Dumfriesshire. As readers are doubtless aware, this firm specialise in the genus, and the evidence tha tthey meet with unqualified success in their cultivation is furnished by the well grown plants of many species and varieties which they put up. From the dwarf and rather rare Primula aurantiaca—perhaps better known to enthusiasts as 21501 Forrest—to the tall, handsome and more common P. pulverulenta, one met all grades. In the sikkimensis clan, there were several plants of the type species which, if examined closely, showed the enormous variation which is met with in this species. Another member, P. flexilipes, of more slender habit than sikkimensis and with uptilted green bells of a pale yellow colour, was also there. The dainty P. Giraldiana was representing the muscaroides group and was characteristic with its white mealy stems and handsome slightly drooping violet flowers. A few elegant plants of the giant form of P. Littoniana, one of the most popular of the muscaroides, were also there. The large deep lilac cones of this species attracted considerable attention on this table. The candelabras were also to the fore in such species as PP. Beesiana and pulverulenta; while P. Cockburniana was near by with its almost flame-coloured flowers. P. anisodora was there and is always interesting with its dul maroon flowers with a narrow yellow eye. This species might be tried in any future hybridisation work. The results, if successful, would doubtless be full of interest, as the progeny would carry, we should think, unusual coloured flowers. There were many others here, but space forbids a more detailed report. It suffices to say that the primula lover could have spent a most interesting hour comparing the various species, noting their characteristics and learning their peculiarities.

Dr. Macwatt, as is his wont, staged an excellent little table of species and hybrids. PP. capitata, Mooreana and crispata were all there upholding the capitata group, so characteristic with their mealy stems and dense flower clusters. P. Veitchii, representing the cortusoides set, was there, while close by was the dainty P. scotica and the graceful P. effusa. P. chionantha, with its white flowers and sturdy foliage covered with a light, almost golden, meal, was the delegate of the nivalis group, which contains some of the best of our early-flowering primulas. That rather difficult "doer," P. Forrestii, was present, looking quite happy alongside well grown plants of P. Rusbyi. These were, to some extent, overshadowed by the taller and more handsome PP. Littoniana and sikkimensis, but, nevertheless, have a charm all their own. That Dr. Macwatt is still a power to be reckoned with in the world of primulas is unquestioned, and we can only await with expectancy what the exhibit may bring forth in the way of novelties next year.

A CORNER OF MESSRS OLIVER AND HUNTER'S EXHIBIT OF PRIMULAS.

Another exhibit of note was that of Lady Aberconway and the Hon. H. W. MacLaren of Bodnant. Many rare gems, including P. Reidii, were to be seen here all looking well, although, unfortunately, when these notes were written, several had not unfolded their dainty blossoms. P. aurantiaca, which flowered for the first time at Kew last year, was there, with its pretty yellow flowers shading to a deeper yellow in the eye. It is not exactly a species whose beauty enraptures one, but, nevertheless, it holds its own peculiar charm. Of the cortusoides set, we noted P. lichiangensis; while the purple secundiflora was there from the sikkimensis section. Of the "Maximowiczii" section we found P. szechuanica with its floppy flowers and reflexed petals of rather a disappointing greenish yellow colour. The foliage, however, is attractive, with almost white veining on a

Digitized by Google

light green ground. One of the marsh forms, P. Wardii, was present, showing the enormous variation in its flower colour from lilac to mauve. Another interesting species was P. spærocephala, with its mauve mop-headed flower clusters covered in meal. The dainty and fine violet flowers of P. effusa were to be seen nestling beside well grown plants of P. Forrestii; while the lilac rose nodding flowers, almost white with farina, of P. chrysopa also called for admiration. There were many other interesting ones about which much could be written, but space forbids. In conclusion, we offer our congratulations to these keen amateurs and also to their gardener on their excellent exhibit, which was full of interest.

The only other sole exhibit of primulas was that staged by the Aldersey College. This consisted of well grown plants of P. helodoxa laid out in grass, producing a most effective and natural result.

The majority of the alpine exhibitors included either a few species or hybrids on their stands. P. pulverulenta and hybrids including the Bartley strain were especially common. Messrs. Bakers included such species as Cockburniana and helodoxa; while the Chalk Hill Nurseries had Bulleyana, and Messrs. Bees the rare P. chrysopa.

The primula exhibits were on a much higher level than last year, and the standard of excellence reached this year by the majority of the exhibitors will be found hard to equal and still more so to surpass.

ALPINE PLANTS

Although the rock plants did not include many new introductions or thrilling rarities, they showed an even greater variety than last year and, in spite of the backwardness of the season and the earliness of the Show, very few half-hardy plants were called in to help the display. So that a generous opportunity was given to the rock gardener of making personal acquaintance with a very large number of species, almost all of them easily grown and many of them uncommon.

Of general tendencies it could be noted that Gentiana angulosa seems to be gaining appreciation as a vigorous, large and easy form of G. verna. Gentiana pyrenaica made a rather tentative appearance on several stands, but its colour, gentian blue suffused with violet, which is exquisite in even a small clump, is too subtle to show to advantage in a single flower, and as yet only very young plants are being exhibited. If it proves more tractable in cultivation than heretofore, it will be a most valuable re-introduction. It was shown by Messrs. Clarence Elliott and Co. and Messrs. Maxwell and Beale.

Aquilegia flabellata was shown by so many exhibitors that it may be hoped that this beautiful and easy Japanese columbine will soon become more widely known and appreciated. It is quite a dwarf plant, making a clump of fat, grey-green foliage about 8ins. high and carrying its large flowers of pure white (sometimes faintly tinged with lavender about the spurs) very freely on short, stout stems.

Another, much rarer and very interesting columbine, A. viridis, was shown among the new plants by Mr. G. Blaythwayte, and has a fantastic elegance to match its remarkable colour. Two other rock plants, a form of Anemone sylvestris, were shown by Messrs. Jones and Ingwersen, and Viola pedata bicolor by Messrs. Bowell and Skarratt.

Messrs. Prichard and Co. showed several uncommon plants, including a valuable new introduction in two species of cyathodes, little heathery plants from the New Zealand alps with small, waxy-white trumpet flowers very sweetly and strongly scented. C. Fraseri is slightly more compact than C. ericoides, but both are quite dwarf. They are said to have proved perfectly hardy in this climate. The same firm showed Heeria elegans, a Mexican of rather doubtful hardiness but well worth the precaution of taking cuttings to see the winter through in a cold frame. It forms a close mat of dark green oval leaves, from which it throws out long trailing stems each carrying a single large flower, suggesting a four-petalled rubus of deep magenta. Cistus umbellatus, white flowered and very neat and refined made a good background to it. Other interesting plants were the delicate shell pink form of Ramondia pyrenaica and Galium olympicum that imitates a slab of very dense moss till it becomes covered with its small greenish white flowers.

Messrs. Cheal showed Erodium macradenum with apple blossom pink flowers whose two upper petals are marked with a spidery blot of inky purple; E. amarum, a dwarfer woollier form of E. absinthoides, with a profusion of white flowers just flushed with pink; Ourisia coccinea in a form which really does flower; and Viola Thuringia a jaunty harlequin seedling of V. tricolor with the upper petals velvety violet and the lower white with one sharp notch of the violet.

Messrs. Clarence Elliott and Co. showed a good dwarf form of Primula farinosa, deep pink and in some specimens almost red; Orchis ustulata, a minute pyramid of flowers in lavender and white chintz with chocolate-coloured buds at the apex; a finely flowered specimen of Daphne rupestris; Ranunculus parnassifolius; and Viola septentrionalis, a cheerful rampant white violet from America with a blackish violet eye and pencilled eyelashes.

Messrs. Reuthe showed a fine large bush of Erinacea pungens, a silvery, spiny hummock set with bright lavender pea flowers and quite hardy on light soil, though it comes from Spain; Erodium petræum with grey, ferny leaves and flowers faintly flushed and delicately veined with pink; Plantago nivalis, a plantain that has strayed into the mountains and become covered with long, silky white hairs; and Cornus suecica, one of our rarest native plants, a woodlander, suggesting a minute trillium with a black centre.

Mr. Frederick Wood of Ashtead showed a deep pink hybrid of Anemone sylvestris, "Merton Rose," which gives the picture of a very slender single-flowered Anemone japonica (a new introduction); a good mossy phlox, Clear's Seedling, which covers a very dwarf and compact cushion with smallish flowers of a warm deep lavender; some hearty clumps of Oxalis enneaphylla, whose great pearl white goblets are so surprisingly large for such a small plant and harmonise so well with the cool grey-green leaves.

Messrs. Waterer showed the very choice Iris gracilipes with lavender flowers, curiously frail and silken for an iris, carried on stiff, wiry stems; Roscœa cautlioides, that carries its crinkled flowers of luminous sulphur yellow a little awkwardly, a defect that deserves to be remedied by careful selection; Wahlenbergia serpyllifolia, and Pinguicula grandiflora.

Messrs. Gavin Jones and Ingwersen brought together a collection of rare and very interesting plants. Linaria nevadensis, flowering for the first time in England, a slender, trailing snapdragon with velvety brown flowers almost black at the lip, a curious and beautiful colour; Genista horrida, a very dense silvery hedgehog covered in summer with golden gorse flowers; Potentilla fragiformis, with thick, hairy strawberry leaves and soft yellow flowers nearly 2ins. across with a faint ring of orange at the centre; Myosotis spathulata, a dense mat of small spoon-shaped leaves scattered, though rather sparsely, with stemless white forget-me-nots, a new plant from the Antipodes; Ranunculus graminifolius, throwing up heads of glorified and stiffly distinguished buttercups from a tuft of grey, grassy leaves, an admirable plant, though seldom seen in gardens.

Messrs. G. H. Crow showed well grown plants of Dianthus neglectus, a deeply coloured form of Viola Bosniaca and Malvastrum Monroanum, a good plant with trailing sprays of crushed strawberry flowers, but not safely hardy except in a warm wall.

Messrs. E. Scaplehorn showed Lewisia columbianum, a rare plant in cultivation, which gives the impression of a large-flowered Saxifraga Cotyledon, though the white flowers are faintly flushed with pink and delicately veined with red; Dianthus versicolor, a seedling variety of D. neglectus that opens white and slowly turns deeper and deeper pink, giving a pleasant soft effect in a large clump.

The Backhouse Nurseries showed Rosa Rouletti, which appears among the new plants, and a general collection of well known and well grown plants.

Messrs. W. H. Rogers and Son showed their dwarf conifers, Cupressus tetragona minima and cæspitosa, tight little mounds of dark green, the latter a little more rugged in outline than the former; Pinus beauvronensis, a miniature Scots pine that is making a welcome reappearance in commerce; and Erodium chamædrioides rosea, throwing up a profusion of delicately pink flowers from a dense mat of dark green leaves.

Messrs. Whitelegg showed, among many other plants, Stachys corsica, the one really attractive hedge nettle; and Harpur Crewe, the old soft yellow double wallflower with a sweet scent of mignonette that nearly dropped out of cultivation but has been rescued and revalued as it deserves.

Hemsley's Nurseries contrasted the weird eccentricities of their succulents with the prim daintiness of Androsace lactea and the elegance of Erodium pelargonifolium, whose blotched petals faintly suggest an odontoglossum.

Messrs. Skelton and Kirby's exhibit was notable, among other things, for Erysimum rupestris (pulchellum), a very neat little alpine wallflower in sulphur yellow.

Messrs. Rogers of Pickering seemed to specialise in aromatic plants. Origanum aureum, a compact golden marjoram; Thymus nitidus; and a thyme with white flowers densely spotted with crimson named T. puciflorus.

Sheppard's Nurseries showed the white form of Papaver alpinum and Potentilla ambigua, whose flat, golden flowers are so unexpectedly large for the neat tufts of grey-green foliage.

Messrs. Bakers of Wolverhampton showed Haberlea virginalis, which comes nearer than most albinos to improving upon the type, and a rather greyish form of Meconopsis rudis.

Messrs. Maxwell and Beale showed Gentiana pyrenaica and clumps of Andromeda tetragona, both belying their reputation by looking very vigorous and hearty.

Messrs. Tucker's miniature garden was very beautiful in the mass, and also included some interesting individual plants. Œnothera Nuttallii with solitary evening primroses on a rosette of spidery dandelion leaves; Daphne arbuscula, rather like D. petræa growing into a little tree instead of a bush; the magnificent large form of Edraianthus serpyllifolius; and several happy and healthy plants of the most distinguished and challenging of high alpines, Androsace pyrenaica.

Mr. J. Wells, jun., showed Trifolium uniflorum, a prostrate clover from Asia Minor, not a very brilliant thing in itself, but useful as a dull rosy purple carpet for more brilliant plants, such as Geum Borisii, which made a great patch of old gold near by it.

Digitized by Google

STOVE AND GREENHOUSE PLANTS

Though gardening nowadays is much more an affair of the open air than it used to be yet there is usually a tolerably good collection of stove plants at Chelsea, while splendid strains of the more usually grown greenhouse plants are always on view. The display this year was of rather more than average quality, and the climatic conditions tended to keep the less hardy exotics happy-looking.

For combined richness and brilliance of colouring there was no exhibit to compare with Messrs. Blackmore and Langdon's splendid bank of double begonias in the first section of the great tent. Every plant was of perfect habit and furnished with blossoms of the largest size and most perfect camellia form. One could select no particular variety as surpassing the rest in beauty, but the orange-apricot Lord Lambourne attracted attention because of its bold massing, and the rich shell-pink colouring and bold petals of Hilda Langdon was noted by almost every visitor. For a perfect blending of brilliant colours this exhibit would be hard to surpass. Diversity was, as usual, provided by basket begonias on tall stands.

For conservatory decoration or for a fine display at exhibition, there are few flowers to rival the newer hybrid hippeastrums (amaryllis) and, at some past Chelseas, displays by Sir George Holford have aroused the greatest admiration. There was no separate display of the flower on this occasion, but two groups in Messrs. Carter's handsome exhibit contained many first-rate varieties. The Raynes Park firm associated with these some admirable gloxinias, including separate groups of the velvety mauve Premier and the white-throated rosy crimson Cyclops; with Star cinerarias and the ever-improving butterfly plants (schizanthus), besides various hardy and half-hardy annuals commonly used for exhibitions and for conservatory work at this season—clarkia, salpiglossis, Phlox Drummondii and so forth.

After an hour or so's inspection of flaming mollis azaleas, sweet peas, rhododendrons, pot marigolds and so forth, one's eyes ache for the cooler colouring of foliage plants, and the palms in the Orchid Tent (described elsewhere), another exhibit of hardy cypripediums near by, the garden of grasses outdoors and the caladium groups indoors received at least as much admiration as their more brilliant neighbours. One always looks for an exhibit of caladiums at this Show by Messrs. John Peed, but on this occasion it was a remarkably fine group by an amateur, Mr. H. B. Brandt (gardener, Mr. H. Cook), which first met the eye. It would be difficult so to arrange these fine foliage plants that any lack of harmony could be noted; nevertheless, this was a very clever bit of grouping with light and shade cunningly contrived and a nice balance of mass and colouring. With an almost bewildering number of varieties, each exceedingly beautiful in its own way, it was not easy for the amateur to select a few of the best for his own culture, but most people would consider Mikado with foliage in tones of purplish red and bronzy green as good as any among the heavier shades; while Triomphe de L'Exposition, dusky green, veined and reticulated red and rose, makes a strong appeal in the middle colour range, and fine plants of Caladium Guil Mar, the neat little spotted Sir Ernest Shackleton and Mercédes d'Argent took the eye among those of more delicate colouring.

Messrs. Peed's caladiums were duly found, and a very good lot they were, but used on this occasion as a foil for various flowering greenhouse and stove plants. The newest gloxinia-throated streptocarpus were largely shown, including some of almost salmon pink colouring; and it is along this line that further advance should be looked for, size and substance of bloom being now almost all that can be desired. The herbaceous calceolarias in this group were noteworthy, being of good habit and having a fine range of colouring, while the "pockets" were large and "fat." Gloxinias and codiæums (crotons) were also well shown.

On Messrs. Webb's exhibit were to be found again almost all the kinds (barring the hippeastrums) found in Messrs. Carter's exhibit, but here the large-flowered and star cinerarias made the greatest impression, the numerous plants of "Webb's Superb" large-flowered strain being surely as near perfection as this beautiful flower can be expected to reach. The star varieties were, in their way, equally good. Of the gloxinias, calceolarias and schizanthus it must suffice to say that they upheld the reputation of the firm for these well known specialities. It is to be hoped that no one at the Show who admires Primula obconica overlooked the two groups of richly coloured "gigantea" on show. It is a pity, however, that the blue clings so firmly to the red with this species, thus making the more deeply coloured forms useless for indoor decoration. Altogether a very worthy exhibit.

Mr. H. J. Jones' exhibit of hortensis hydrangeas at last year's Chelsea gave most of us an entirely new conception of the possibilities of the plant, but his effort this year was lighter in arrangement and even more bewilderingly effective. He had a large number of varieties on show, certainly, but the most striking feature was the chameleon-like character of the different sorts. Mme. Moullière is, of course, white or green always, but there was Marechal Foch in every tone from rose through purple with a brilliant blue eye to blue; and Blue Prince, as often as not, was a study in rose and green. Stretches of brilliant blue were, at least in some instances, Mme. Riverain, while corresponding drifts of almost salmony rose proved to be Lancelot. Goliath, Radiant and Parsival were also noteworthy, and the daring combination of vivid green and blue in some plants of the first mentioned would be hard to match with any other flower. Some visitors obviously admired the hortensia, others struggled hard to avoid expressing admiration, but no one could ignore this most impressive group.

Messrs. Godfrey and Son showed a very fine compact strain of Schizanthus grandiflorus, which in sheltered localities should be good for summer bedding as well as for conservatory and indoor decoration.

Messrs. Watkins and Simpson also had a fine group of schizanthus covering a very wide and effective range of colouring, but even more notable was their strain of cineraria which they call "multiflora." This has the freedom to flower of the star varieties, with a compact habit comparable to that of the large-flowered strains. The individual blooms are shapely, intermediate in size between the large-flowered and the "stars" and self-coloured. The colour range is wide, and includes some very beautiful tones. A strain of Salvia splendens called Harbinger retains the normal gorgeous colouring of the type, is of good habit, and specially notable in that the bushy plants on show—and smothered in blossom—had been grown from seed in four months. Only those who have raised Salvia splendens from seed will properly appreciate what an advance this denotes.

The schizanthus was much in evidence this year. Another fine group of this flower was noted on the stand of Mr. Alfred Dawkins, but these "dwarf hybrids" were obviously nearer the wisetonensis set than the grandiflorus. Beautiful rosy tones were much in evidence, and the habit of the plants left nothing to be desired.

The zonal pelargonium is no longer a favourite flower, yet its bright colouring and ease of culture should commend it to the amateur who wishes a gay display at almost any season. Mr. R. J. Case had a very bright display which included the salmon-rose Taurus, the double salmon The Speaker and the quaint starry Fascination. The brilliant rosy scarlet ivy-leaved variety Sir Percy Blakeney was also in evidence.

Messrs. Jarman and Co. supplemented their incomparable sweet sultans with bunches of zonal pelargonium blossom and plants of a number of kinds of scented-leaved pelargoniums, which, like other kinds with scented foliage, are fast returning to favour. Star cinerarias were also shown.

Messrs. L. R. Russell set up a fine group consisting almost entirely of the choicer stove species, though the nearly hardy Hoya carnosa (just opening its waxy bloom trusses) was included. Splendidly flowered specimens of anthurium and the pretty Clerodendron Balfouri stood out from a grouping of caladiums, codiæums, aralias and dracænas. Of the last named Père Charon and Victoria were especially attractive.

Messrs. James Cypher and Sons in a group mainly consisting of orchids had fine plants of the very useful Statice intermedia and also brilliant anthuriums.

PALMS & SUCCULENTS

Messrs. Robert Green, Limited, had a large collection of palms, and many of them were fine trees. Large specimens of the spineless palms, Kentia Belmoreana and K. Fosteriana, were exhibited. The glaucous leaflets of Cocos australis were effective, and very graceful were the spineless palms, Areca Baueri and A. sapida, whose pinnate leaves form terminal clusters. Chamærops Fortunei, the fan-leaved palm, and the noble Phœnix canariensis, which is of rapid growth, and the pygmy Phœnix, P. Rœbelinii, with its shiny, dark green leaves, were among the collection. Raphis flabelliformis and Cocos flexuosa, were also in good condition.

Two groups of succulents were exhibited and both were varied, and the plants were remarkably healthy. These curious plants possess a fascination of their own, and although they are not grown to any large extent, small collections of tiny succulents growing in bowls are becoming very popular. Mr. S. Smith had the largest exhibit, and many interesting specimens were among his plants. Echinocactus Grusonii was looking in very good condition; Cereus flagelliformis, with its long, snake-like growth; Mamillaria pusilla, with whitish flowers about to bloom; and the thick columnar Cereus Roezlii, were all noticeable.

Miss S. S. Thompson staged the other exhibit of succulents. Minute pots of healthy-looking plants were very attractive. Mesembryanthemum tigrinum, the hairy Pilocereus senilis, Opuntia clavarioides Mamillaria stellata and M. haageana, were noticeable.

ORCHIDS

Sir Jeremiah Colman, Bt., Gatton Park, Surrey (gardener, Mr. Collier), was awarded a gold medal for an exquisite group of rare species and choice hybrids. Among the former were finely grown examples of Ærides crispum, Maxillaria Sanderiana and a varied assortment of Masdevallias. One of the interesting features was the splendid type of Lycaste Skinneri, the vigorous plants had many flowers of fine substance. Dendrobiums were well represented by varieties of Gatton Sunray and illustre; while cymbidiums included selected varieties of Pauwelsii, Emery and President Wilson. Odontioda Lady Colman and Oda. Madeline were noteworthy for

Digitized by Google

their brilliant reddish colour. Lycaste locusta, with large dark green flowers, proved most interesting to many of the visitors.

Messrs. Charlesworth and Co., Haywards Heath, received a gold medal and the congratulations of the Council for a magnificent group, every plant being displayed to its fullest effect. The centre was composed of many plants of Odontoglossum crispum xanthotes and other white-flowering kinds, thus making a fine contrast to the red-flowering odontiodas on each side. Among the newer hybrids were distinct odontonias, many miltonias with blotching on the labellum, and some well coloured brasso-cattleyas. Lælio-cattleyas were best represented by Fascinator, which is still a favourite; while cymbidiums were noted in Ceres with three vigorous spikes of carmine-coloured flowers.

Mr. H. T. Pitt, Rosslyn, Stamford Hill (gardener, Mr. Thurgood), was awarded the challenge cup given by the trade orchid growers, thus winning it for the second time. His group contained many rare species such as two finely grown plants of Bulbophyllum macrobulbon, fine forms of Cattleya Mendelii, Cattleya citrina, with its pendulous flowers of citron-yellow colour, and a large plant of Ansellia africana. Among the cypripediums were Enchantress, with flowers of emerald-green colour, and the pretty glaucophyllum. Miltonia William Pitt, of rich crimson colour, came in for well deserved appreciation.

Mr. Albert C. Burrage, Beverly, Mass., U.S.A., created a most unexpected spectacle by sending over a large quantity of hardy New England cypripediums, accompanied by pine trees and American ferns, the whole consignment weighing upwards of five tons. The plants came over early this year in cold storage and were brought into flower in Mr. E. M. Preston's garden at Hayes, Kent (gardener, Mr. Woods). This unique exhibit was recognised by the award of a silver-gilt Lindley medal. Mr. Burrage has very generously presented the whole of this exhibit to English gardens, the recipients being Sir Jeremiah Colman, Bt., Lieutenant-Colonel Sir George Holford, K.C.V.O., and the Royal Botanic Gardens, Kew.

Messrs. Stuart Low and Co., Jarvisbrook, Sussex, were awarded a silver cup for a meritorious exhibit containing many excellent cymbidium hybrids, also a large plant of Cymbidium Loweanum concolor. Among the cattleyas was C. Mossiæ Arnoldiana, a favourite of many years ago, also C. intermedia Aquinii, with its petals flushed with purple, and alongside of it the remarkable C. Suavior, which has the petals similarly coloured. Dendrobiums were another feature of this exhibit, and there were many well flowered examples of the popular kinds. Masses of red were imparted by well flowered plants of Renanthera Imschootiana, and at each end was a large batch of Lælio-Cattleya G. S. Ball, with numerous flowers of orange-red colour.

Messrs. Cowan and Co., Southgate, N., were awarded a silver cup for a neatly arranged exhibit, the back of which was composed of the bright yellow Oncidium Marshallianum, aud various cymbidium hybrids, including C. Beryl, with a boldly marked lip, and fine varieties of C. Pauwelsii. A feature of this exhibit was the section of albino cypripediums, these embracing Maudiæ, Emerald, Curtisii Sanderæ and callosum Sanderæ, in all of which the typical purplish colour was absent. Lælio-Cattleya Hassallii alba, with a couple of large flowers, occupied a central position, and among the odontiodas mention may be made of Grenadier, with a branched spike of reddish flowers, and Murillo, with many scarlet-coloured flowers.

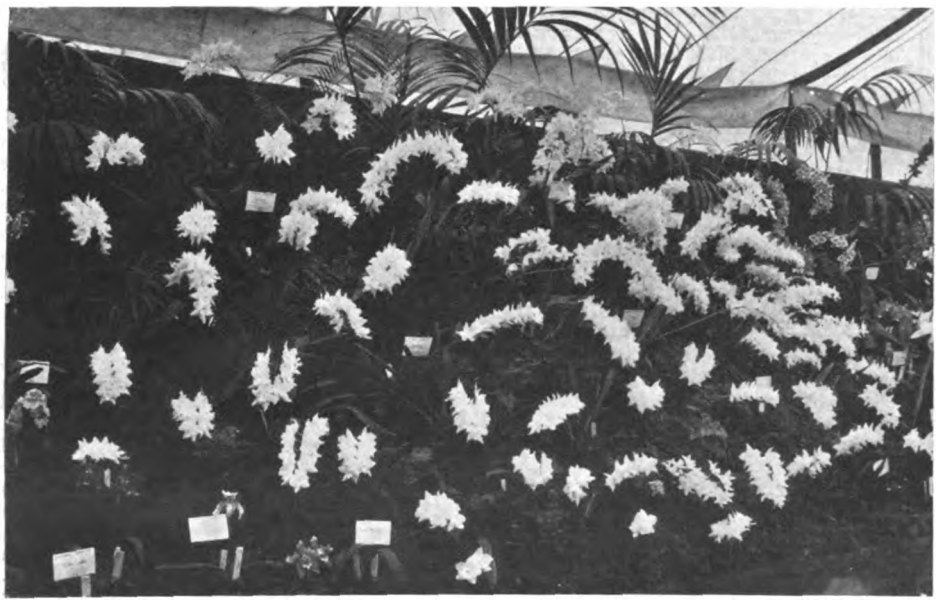
Messrs. Cypher and Sons, Cheltenham, received a silver-gilt Flora medal for an attractive exhibit in which the centre was composed of Brasso-Cattleya Digbyano-Mendelii, with immense flowers having the expansive labellum prettily fringed. On each side were well grown plants of Cypripedium Maudiæ and C. Lawrenceanum, while in front were excellent specimens of Masdevallia species. Lælia purpurata, one of the favourites of the old Temple shows, was here seen in perfection; also Lælio-Cattleya Fascinator, and some strong plants of Dendrobium formosum with large white flowers. An attractive plant was staged in Cypripedium macrochilum giganteum, with three curious flowers, the petals being considerably elongated. Lycaste Skinneri showed up well, and a pretty odontoglossum of yellow colour was seen in a hybrid named Eva.

Messrs. Mansell and Hatcher, Rawdon, Leeds, were awarded a silver-gilt Flora medal for a group containing numerous examples of Lælio-Cattleya Fascinator, always effective at this period of the year. Cattleya Schroederæ and C. Mossiæ stood out prominently, the latter being represented by a variety named striata, in which the segments were stained with a deep rose. Among the cypripediums was a distinct form of Lawrenceanum, with greenish flowers, also C. Godefroyæ, of round formation.

Messrs. Flory and Black, Slough, received a silver-gilt Banksian medal for the best group of cattleyas. Considering the dull season, this exhibit was very praiseworthy. Fine examples were staged in Tityrus, of large size; Heatherwood, equally attractive; and Empress Frederick var. Vesuvius, of rich colour. Albino cattleyas included Irene and Magali Sander, pure white except for some yellow in the throat; and The Bride, in which the yellow is entirely absent. The well known Cattleya Mendelii, formerly seen in quantity at the spring shows, but now scarce, was here staged in a variety having the labellum of violet-purple.

Mr. Harry Dixon, Wandsworth Common, was awarded a silver Flora medal for an effective exhibit containing two large plants of Ansellia africana, somewhat darker than usually seen. On each side were selected varieties of Lælio-Cattleya luminosa and L.-C. Martinettii; while in front were most of the popular cypripediums of the spring-flowering type.

Messrs. Sanders, St. Albans, received a silver Flora medal for a small but choice selection of species and hybrids, the former including Bifrenaria pubigera, with pretty flowers; Cymbidium Devonianum; select forms of Odontoglossum crispum and Cypripedium insigne Sanderæ, the latter flowering out of season.



THE CENTRE PIECE OF ODONTOGLOSSUM CRISPUM ON MESSRS. CHARLESWORTH'S STAND.

NEW & RARE PLANTS

FIRST CLASS CERTIFICATE.

PÆONIA OBOVATA ALBA.—A popular description of this beautiful plant might well be a herbaceous peony with delicately beautiful reddish purple tinted leaves and bearing dazzling white magnolia flowers. The purity of the white cup-shaped flowers is enhanced by the little cluster of bright yellow stamens and green purple-tipped stigmas. It is a native of Hupeh, China. Shown by Mr. J. C. Allgrove.

AWARDS OF MERIT.

ANEMONE SYLVESTRIS SPRING BEAUTY.—This is a greatly improved variety of the snowdrop windflower. The solitary, rounded milk-white flowers are borne on downy stems about a foot in height, rising well above the dwarf cut foliage. Shown by Messrs. G. Jones and Ingwersen.

AZALEA COQUETTE.—A hardy deciduous azalea of uncommon type. Its appearance suggests a hybrid between Ghent and occidentalis varieties, but no information was forthcoming. It may almost be described as a Ghent azalea with larger and more widely expanded flowers, which are of soft pink colour with a yellow standard.

AZALEA MARIAN MARRIMAN.—Of similar type to the foregoing, but of bright yellow colour with orange spots and flushing on the standard.

AZALEA MARY WATERER.—Another beautiful hardy azalea of the same type and lovely creamy white colour lightly flushed on the outer parts of the petals with apple-blossom pink. There is just a suggestion of yellow in the centre of the flowers. These three lovely hardy deciduous azaleas were shown by the executors of the late Mr. Anthony Waterer.

AZALEA MARY.—This is stated to be a cross between A. malvatica and A. Kæmpferi. In general appearance it is a larger-flowered example of the dwarf Japanese azaleas, which are shown so frequently during the spring. The flowers are of bright rose pink colour with carmine spots on the upper segments. Shown by Messrs. T. H. Van Nes.

Digitized by Google

CARNATION RED LADDIE.—A reddish old rose coloured sport from the well known variety Laddie, which Mr. Engelmann has shown so consistently well for many months past. The new variety has somewhat larger flowers of splendid shape on long, graceful stems, and its uncommon colour will make it a very popular variety. Shown by Mr. C. Engelmann.

DIOSMA UNIFLORA.—This is a shrubby plant bearing wiry erect stems furnished with narrow linear leaves crowned with five-petalled, widely opened flowers rather over an inch across. The lovely flowers are of milk-white colour, and each petal has a rosy carmine line running from its base half-way up the centre. Shown by the Rev. A. T. Boscawen.

PRIMULA NIVALIS.—A Chinese primula. It makes a fairly dense tuft of long, fleshy, strap-shaped leaves of dark pea green colour, and from these rise slender stems 9ins. to 12ins. high crowned with heads of flattish deep lilac flowers with white eyes. Shown by Mr. A. K. Bulley.

RHODODENDRON A. GILBERT.—Apparently one of the half-hardy hybrids. It bears a large truss of creamy pink flowers which are flushed with rose on the outer parts of the petals. Shown by Mr. T. H. Lowinsky.

R. TITTENHURST BELLE.—A most beautiful "Riviera" variety, obtained by crossing R. Aucklandii with a Corona seedling. It has a particularly long, erect truss, perfectly furnished with large flowers most delightfully stippled with rich blush pink. The central stem and stalks of the flowers are stained deep crimson. Shown by Mr. T. H. Lowinsky.

R. GLORIOSA.—A large truss of beautiful blush pink flowers which are shaded to a darker tone on the edges. The stalks are of reddish purple colour. Shown by Messrs. R. Gill and Son.

R. GOLDSWORTH YELLOW.—The great garden value of this hardy hybrid rhododendron was well seen in the large group on the grass. It is a compact grower and bears medium-sized trusses of deep primrose yellow flowers spotted with green on the upper segment. Shown by Mr. W. C. Slocock.

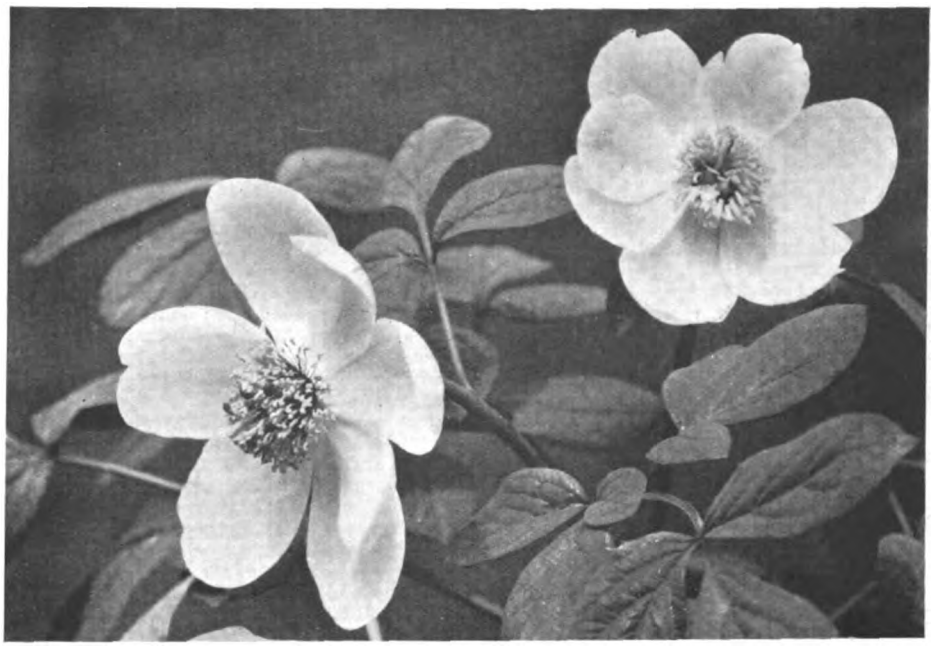
R. LEDOIDES.—A tiny little plant from China, only a few inches high, was shown, and this bore five trusses of fascinating miniature tubular whitish flowers. Shown by Mr. A. K. Bulley.

R. T. H. VAN NES.—A brilliant hybrid rhododendron bearing large trusses of widely expanded flowers of pale blush colour which is deeper on the outer parts of the flowers. Shown by Messrs. T. H. Van Nes.

TELOPEA OREADES.—It is an erect-growing large shrub bearing entire leathery ovate lanceolate leaves and dense heads of rich crimson flowers of similar shape to those of Eribothrium coccineum. The telopas are known as "waratahs" in Australia. Shown by the Rev. A. Boscawen.

ROSA SUPERBA.—A dwarf perpetual polyantha rose of great beauty. The compact floriferous trusses have small fully double flowers of deep crimson colour very slightly flushed with plum purple. Shown by Messrs. Wm. Cutbush and Sons.

STAPHYLEA HOLOCARPA.—Flowering sprays of a deciduous shrub, which is a native of Central China. Flowers of a whitish-pink hanging in short corymbs. Very fine. Shown by Sir George Holford.



THE HANDSOME MAGNOLIA-LIKE BLOSSOMS OF PÆONIA OBOVATA ALBA.

THE MILK WHITE FLOWERS TINGED WITH ROSY CARMINE OF DIOSMA UNIFLORA.

ORCHIDS.

FIRST CLASS CERTIFICATES.

LÆLIO-CATTLEYA HASSALLI ALBA, Cowan's variety (L.-C. Britannia × C. Warscewiczi).—This handsome hybrid bore a couple of large flowers, the sepals and petals of thick texture, creamy white, the roundly formed labellum bright purple with a narrow margin of white, the throat bright yellow. Shown by Messrs. Cowan and Co., Southgate, London, N.

ODONTIODA HIAWATHA VAR. ROYALTY (Oda. Charlesworthii × Oda. Coronation).—A beautiful hybrid bearing an erect spike of eleven flowers of rose tint, the sepals and petals almost covered with brilliant rose-scarlet, thus making a most attractive object. From Messrs. Charlesworth and Co., Haywards Heath.

AWARDS OF MERIT.

CATTLEYA CHELSEA (C. Empress Frederick × C. General Pulteney).—One of the finest cattleyas in the Show. The two flowers were large, the petals broadly developed and of erect habit, deep mauve, the immense labellum crimson-purple, crisped at the margin and with gold veining at the apex of the throat. Exhibited by Messrs. Flory and Black, Slough.

CATTLEYA SUAVIOR VAR. HERCULES (intermedia Aquinii × Mendelii).—The best variety yet seen of this interesting hybrid, in which the peloriate nature of the first mentioned parent is perpetuated in a marked degree. Flowers of rose colour, the petals heavily flushed with purple at the extremity, thus resembling the purple coloured labellum. Shown by Messrs. Stuart Low and Co., Jarvisbrook, Sussex.

CYMBIDIUM VIRGO VAR. GUINEA (Pauwelsii × Woodhamsianum).—One of the showiest of the popular cymbidium hybrids. The vigorous plant carried an extended spike of eighteen large flowers of greenish gold colour, the labellum having a crimson band on the apex of the front lobe and spotting of similar colour on the two lateral lobes. Shown by Messrs. Stuart Low and Co., Jarvisbrook, Sussex.

ODONTOGLOSSUM CRISPUM VAR. PRISCILLA.—One of the finest of the garden-raised plants of this species. The spike had been disbudded to four flowers, which were very large, the petals almost meeting in front of the dorsal sepal. Segments slightly tinged with light rose, the labellum having a few

Digitized by Google

reddish spots. This plant also carried a seed-pod. Shown by Mr. Robert Paterson, Stamperland, Cathcart, Glasgow.

ODONTIODA ORESTES VAR. MAJESTICA (Oda. Coronation × Odm. percultum).—The tall spike of this hybrid bore seven flowers with roundly formed segments of a pleasing rose tint and slightly spotted with reddish purple. Exhibited by Messrs. Cowan and Co., Southgate, London, N.

MILTONIA PRINCESS MARY VAR. MAJALIS (Bleuana × Hyeana).—The horizontally produced spike bore four large flowers of the well known M. vexillaria habit. Sepals flushed at the base with crimson, the petals to a much stronger degree, labellum stained with rose, and with a ray-like mask of brownish colour at its base. Staged by Messrs. Charlesworth and Co., Haywards Heath.

CYMBIDIUM VICTRIX (Venus × Alexanderi).—This elegant hybrid bore two erect spikes of large buff yellow flowers, the labellum having a brownish zone around the apex. Shown by Messrs. Sanders, St. Albans.

CULTURAL COMMENDATION.

ODONTIODA CORA VAR. PRINCESS (Oda. Coronation × Odm. eximium).—An excellent cultural result, in which the inflorescence consisted of nineteen large flowers, with well developed colouration. Staged by Messrs. Charlesworth and Co., Haywards Heath.

ODONTIODA WEST POINT BEAUTY (Oda. Bradshawiæ × Odm. eximium.)—A truly remarkable result of cultural ability was seen in this plant, the branched spike carried no fewer than seventy-six well developed flowers of purplish-rose colour. Shown by Messrs. Charlesworth and Co., Haywards Heath.

SUNDRIES

On either side of the long avenue leading from the Hospital entrance to the rock gardens, exhibits of horticultural sundries of every kind were packed tightly together. Along the main entrance as well, more garden requisites were displayed. It was interesting to compare the products of the various firms and to examine all their latest inventions.

Spraying and limewashing machines which were sound in the principle of their design and in material were exhibited by the makers, the "Four Oaks" Spraying Machine Company. The "Four Oaks" "Battle" pattern is one of the best spraying machines on the market for work on a large scale.

Messrs. C. H. Pugh, Limited, were showing "Atco" motor mowers of various sizes.

Tools, insecticides, fertilisers, syringes and all kinds of garden requisites were shown by Messrs. Smith and Ellis, Limited. A small hand sprayer exhibited by this firm has caused many enquiries. This pneumatic machine is called the "Con-o-mist" sprayer, and it is certainly easy to use and quite efficient.

Messrs. James Carter were exhibiting Royal Doulton flower bowls and vases as well as glass vases, and a great variety of sundries. Tools, knives, fertilisers, etc., were there in plenty.

Messrs. Ransomes, Sims and Jefferies, Limited, the great lawn mower firm, had a selection of their mowers.

Messrs. Samuel McGredy and Son, the Irish rose growers, had an exhibit of rose accessories: Fertilisers, insecticides and a fungicide called "Kuremil," prepared for the prevention and cure of mildew.

A sweet perfume came from the stand of Messrs. Allwood Brothers. Among packets of carnation seed and tins of carnation fertiliser were bottles of perfume made from this firm's own carnations.

Messrs. John Shaw and Sons were showing the "Governor" lawn mower both with and without an extra roller attached.

Messrs. Bakers had an exhibit of strong netting and supports for hard tennis court surrounds. This is a line in which they specialise.

Lawn mowers and rollers were shown by Messrs. A. Shanks and Sons, a firm who manufacture some of the most reliable and long-lasting of all lawn mowers. Every kind of lawn mower, including those driven by motor, were displayed.

Among the spraying machines, fertilisers, slug-killers and insecticides on the stand of the Stonehouse Works Company was a handy appliance for distributing fertilisers called the Stonehouse Duplex Distributor.

Messrs. Thomas Green and Son, Limited, had a collection of lawn mowers, and among them there could be found mowers to suit every type of lawn.

A patent and remarkably cheap pruner, known as Camp's "P.C." Pruner, which met with favour from many people, was exhibited by the makers, Messrs. Camp and Co.

Messrs. Abol, Limited, had an exhibit of all the famous "Abol" syringes, spraying machines and spraying mixtures.

Major C. Walker was exhibiting his fruit tree protectors suitable for wall fruit, bush tree fruit and fruit plantations.

Messrs. Robinson Brothers, Limited, were showing, among other sundries, "Carmona" Plant Food, "Velvas" lawn sand, "Multiple" worm-killer, watering cans, tools, syringes and spraying fluids.

Mr. J. Singleton was very busy selling his patent watering can attachment which does away with the need for a rose. The "Nuespray" attachment can be fitted to any size of can.

Mr. John Pinches was showing, besides weather-proof labels, plant-holders and bloom-protectors.

The Chase Continuous Cloche Company were showing vegetables and flowers which have been grown under their cloches. The plants were much in advance of those grown without protection. The firm was also showing a fruit-storing stand.

Hundreds of little plants in square "Fibrex" pots attracted much attention. They were exhibited by Mr. J. N. Harvey. In these pots transplanting difficulties are greatly reduced, as the plant is not removed from the pot but planted without disturbing the pot in which the roots are embedded.

Messrs. Woodworkers, Limited, had two most useful propagating frames which looked to be perfectly sound.

Several blocks of turf, showing the beneficial effects of a special fertiliser, were exhibited by the Key Fertiliser Company.

The House and Garden Sundries Company were exhibiting wall clips, fruit protectors and various horticultural requisites.

Messrs. Corry and Co., Limited, the makers of the well known Corry's white fly fumigant, had insecticides and manures.

A reagent for the conversion of straw, bracken or any garden rubbish into synthetic farmyard manure was exhibited by Messrs. Adco, Limited.

Heating apparatus interests chiefly the owners of large greenhouses; to them the exhibit of boilers manufactured by Messrs. Jones and Attwood, Limited, would appeal.

Vegetables and fruit fertilised by the plant food supplied by Messrs. Prentice Brothers were shown on the stand of this firm. Pure Ichthemic guano, "Tomorite," lawn sand, potato fertiliser, etc., were there.

"Katakilla," a special winter wash, hand sprays and a slug-killer were exhibited by Messrs. Cooper and Nephews.

Every imaginable horticultural requisite was exhibited by Messrs. Thomas Gunn, Limited.

The Willmott Rival Plant Stakes, patented by Mr. H. J. Greenwood, are among the quickest to fix and most invisible of any plant stake.

A cheap rustless and adjustable plant-holder, named the "Ideal," was exhibited by Mr. E. Sydney.

Messrs. Martineau and Smith had a large exhibit of spraying machines and syringes.

The "Diamond" extension ladders, which Messrs. Drew, Clark and Co. were exhibiting, have been reduced in price.

Pneumatic spraying machines were shown by Messrs. Holder-Harriden, Limited.

The J. P. Super Lawnmowers, Limited, were demonstrating the merits of adjustment of their mower by hand wheels; all the working parts being enclosed and running on ball bearings in an oil bath.

The Dryad Cane Furniture Company exhibited "Dryad" cane chairs and tables.

The Cooper-Stewart Engineering Company, Limited, were demonstrating the "Rain King" lawn sprinkler and the "2-Purpose" Rain King sprinkler.

Horse boots, sprinklers, spike rollers, lawn sand distributors, shoe-cleaning apparatus comprised the exhibit of Messrs. Pattisson and Co.

"The Sprayer of a Thousand Uses" was exhibited by the Eclipse Spraying Company.

Messrs. Dennis Brothers were exhibiting the motor lawn mower which gained an award of merit for its excellent work at the R.H.S. motor mower trials held recently.

The Acme Patent Ladder Company had an exhibit of ladders, steps, barrows and trestles.

The bird-boxes in the exhibit of Messrs. Arthur H. Moorton, Limited, were an interesting feature. Sundials, bird-baths and garden ornaments were also shown by this firm.

A varied and good exhibit of garden ornaments, paving both in stone and sand-faced brick, was staged by Messrs. Sanders and Co.

Garden tents, ornaments, garden chairs and other furniture were shown by Messrs. A. W. Gamage, Limited; Harrods, Limited; W. Wood and Son; Sutton and Sons; and Gaze's, who also showed hard tennis courts.

Messrs. Skinner, Board and Co. showed two "Wire-tension" greenhouses; D. Swain and Co., greenhouses, frames, etc.; and W. Duncan Tucker and Sons, Limited, greenhouses and frames.

Messrs. Charles P. Kinnell and Co., Limited, had a large exhibit of greenhouse heating apparatus, boilers of kinds such as the "Robin Hood," the "Bisson" and the "Rochford." They were also showing radiators for heating a winter garden.

A variety of ornaments in artificial stone were shown by Messrs. Pulham and Sons.

Mr. Ernest Dixon had a few teakwood garden chairs and tables by the side of his sunk garden.

Owing to lack of space, we are unable to complete the list of sundries until our next issue.

OFFICIAL LIST OF AWARDS

CHALLENGE CUPS.

Sherwood Cup, for the most meritorious group (excluding orchids): To Messrs. C. Engelmann, Limited.

"Daily Graphic" Cup, for the best rock garden: To Mr. G. G. Whitelegg.

Cain Cup, for the best exhibit by an amateur: To the Hon. Sir John Ward, K.C.V.O. (gardener, C. Beckett).

Orchid Challenge Cup, for the best exhibit of orchids by an amateur, on a space not exceeding 60 sq. ft. Only those may compete who employ not more than three assistants in orchid houses (including the head gardener): To H. T. Pitt, Esq. (gardener, F. W. Thurgood).

SPECIAL CUPS.

Allwood Carnation Bowl, for the best group of carnations exhibited by an amateur: To Sir William E. Cain, Bt. (Executors of the late).

Digitized by Google

Roses.—Gold medal: To Hicks, E. J. Silver cups: To Allen, A. J. and Co. Silver gilt flora medal: To Cutbush and Son, Limited. Silver-gilt Banksian medal: To Cant and Sons, B. R. Silver flora medal: To Cant and Co., F.; Paul and Son, Wm. (Chaplin). Silver Banksian medals: To Pemberton, J. H.; Prince, George.

Formal Gardens, etc.—Gold medal: To Wallace, R. and Co.; Carter and Co., J. Silver cups: To MacDonald, J.; Vernon Bros.; Winder, R. Silver-gilt flora medal: To Bakers, Limited; Cuthbert, R. and G.; Dixon, Ernest. Silver flora medals: To Wood and Son, Wm.; Cheal and Sons, Limited; Gaze and Son, Limited, W. H.; Johnstone Garden Contractors, Limited; Maxwell and Beale. Silver Banksian medals: To Horsecombe Quarries; Klinkert, J.

Tulips.—Gold medal: To Barr and Sons. Silver cups: To Dobbie and Co., Limited. Silver gilt flora medals: To Watts, W. A.; Longford, H. G. Silver-gilt Banksian medal: To Bath, Limited, R. H. Silver flora medals: To Pearson and Sons; Maytham Gardens. Silver Banksian medal: To Paul, E., and Co.

Carnations.—Gold medal and congratulations: To Engelmann, C., Limited. Gold medal: To Allwood Bros. Silver-gilt Banksian medal: To Low and Co., Stuart; Douglas, James. Silver flora medal and Allwood Cup: To Cain, Sir W. E., Bt. (Executors of the late). Silver Banksian medal: To Luxford and Co., Keith.

Fruit and Vegetables.—Gold medal: To Ward, Major the Hon. Sir John (gardener, C. Beckett); Gibbs, Hon. Vicary (gardener, E. Beckett). Silver cups: To Bunyard and Co., Limited; Laxton Bros. Silver Hogg medal: To Rivers and Son, Limited. Silver Knightian medal: To Sutton and Sons. Bronze Hogg medal: To Vickers, V. C. (gardener, W. Watkins).

Rock Gardens.—Gold medal: To Whitelegg, G. G. Silver cups: To Brook, H.; Pulham and Son. Silver-gilt flora medal: To Elliott, Limited, Clarence. Silver flora medal: To Cutbush and Son, Limited. Silver Banksian medal: To Hodsons, Limited; Jones and Ingwersen, Gavin.

Orchids.—Amateur Exhibits.—Gold medal: To Colman, Sir J., Bt. (gardener, J. Collier). Silver cup: To Pitt, H. T., Esq. (gardener, F. W. Thurgood). Silver-gilt Lindley medal. To Burrage, A. C., Esq.

Orchids.—Trade Exhibits.—Gold medal and congratulations: To Charlesworth and Co. Silver cups: To Cowan and Co.; Low and Co., Stuart. Silver-gilt flora medals: To Cypher and Sons, J.; Mansell and Hatcher. Silver-gilt Banksian medal: To Flory and Black. Silver flora medals: To Dixon, H.; Sanders,

Sweet Peas, etc.—Gold medal and congratulations: To Dobbie and Son, Limited. Silver-gilt Banksian medals: To Dickson and Sons, Limited, Alex.; Smith, S. Silver flora medal: To Thompson, Miss S. Silver Banksian medal: To Bolton and Son, R.

Alpine Plants, etc.—Gold medal and congratulations: To Aberconway, Lady and the Hon. H. D. MacLaren. Silver cups: To Oliver and Hunter. Silver-gilt flora medals: To Hemsley, H.; Rogers and Son, Limited, W. H.; Jones and Ingwersen, Gavin; Tucker and Sons, R.; Elliott, Limited, C.; Macwatt, Dr. J. Silver-gilt Banksian medals: To Bakers, Limited; Bowell and Skarratt; Prichard and Sons M.; Carter Page and Co., Limited; Maxwell and Beale; Prichard and Co; Scaplehorn, E.; Walters, W. H. Silver flora medals: To Backhouse Nurseries (York), Limited; Cheal and Sons, J.; Aldersey Horticultural College; Central Garden Supplies; Sheppards; Skelton and Kirby; Rogers, R. V. Silver Banksian medals: To Crow, Esq., G. H. (gardener, A. Tingley); Reuthe, G.; Hopkinson, Miss K. Bronze flora medal. To Dixon, E.

Shrubs.—Gold medal: To Wallace, R. W., and Co. Silver cups: To Cuthbert, R., and Co.; Reuthe, G.; Koster and Sons, M.; Hillier and Sons. Silver-gilt flora medal: To Waterer, Anthony (Executors of the late); Waterer, Sons and Crisp, Limited, J. Donard Nursery Co.; Notcutt, C. R.; Yokohama Nursery Co., Limited; Charlton and Sons, A.; Fromow and Sons, W.; Russell, Limited, L. R.; Jackman and Son, G. Silver-gilt Banksian Medals: To Cheal and Sons, J.; Cutbush and Son, Wm.; Stuart Low and Co.; Gill and Son, R. Silver flora medals: To Endtz, N. J., and Co.; Lewis, T.; Slocock, W. C.; Turner, C.; Watson and Sons, Limited, W.; Green, Limited, R. Silver Banksian medal: To Harrods, Limited. Bronze flora medal: To Whitelegg, G. G.

Herbaceous.—Gold medals: To Blackmore and Langdon; Bunyard and Co., G.; Carter, J., and Co.; Russell, Limited, L. R.; Sutton and Sons; Jones, H. J. Silver cups: Perry, Amos; Webb and Sons (Stourbridge); Brandt, Esq., H. B. (gardener, H. Cook). Silver-gilt flora medals: To Wood, F. G.; Cutbush and Son; Waterer, Sons and Crisp, J. Silver-gilt Banksian medals: To Ellison, H. N.; Ladhams, Limited, B.; Peed and Son, J.; Prichard and Sons, M.; Scaplehorn, E.; Storrie and Storrie; Watkins and Simpson; Artindale and Son, Wm.; Bees, Limited; Blackmore and Langdon; Carter Page and Co., Limited; Chalk Hill Nurseries; Dawkins, A.; de Goede Bros.; Orpington Nurseries Co.; Toogood and Sons, Limited. Silver flora medal: To Clarke, H.; Hewitt and Co., Limited; Jarman and Co.; Maytham Gardens; Miller, G. A.; Yandell, William; Smail and Co.; Wells, Junr., W. Silver Banksian medals: To Carlile, T.; Gibson and Co., G.; Godfrey and Son; Maytham Gardens; Reamsbottom and Co.; Rich and Co. Bronze flora medal: To Case, R. J.; Cheal and Sons, J.

SIMPLE GARDENING

ROSES UNDER GLASS AND IN POTS.

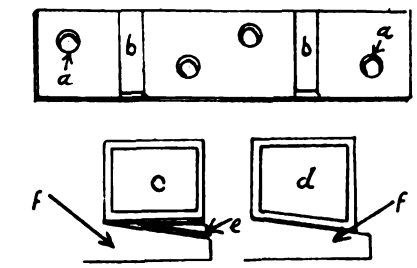
ROSES are grown very extensively under glass, both planted out and in pots, by nurserymen and growers for cut blooms and as small specimens in pots for market. Amateur cultivators also make efforts to grow the plants in this way—some very successfully, others with but partial success. Those who are just beginning to grow roses thus, and so lengthen the flowering period, may make mistakes. Usually, the plants are well cared for while they are making the new wood—tender shoots containing the flower buds—and during the actual flowering stage; but afterwards are often neglected. Of course, those plants growing in borders are permanent and must remain under glass throughout the summer months, but the pot-grown ones should be placed outside directly the flowers have faded. If retained under glass there will be a second crop of flowers; but the cultivator is not justified in keeping them in the house for this, except in seasons when blooms are needed for some special purpose. Abundance of air should be admitted to the permanent rose plants; any dying shoots and those very young and mildewed should be cut out, the branches well shaken to get rid of old leaves, then syringe thoroughly with "Abol" and, afterwards, with clean water. Keep down aphides—fumigate for this purpose—and so reap a good early autumn crop of clean flowers. By judicious pruning there will be a few blooms available nearly all through the summer. The pot plants should also be cleaned; then plunge the pots to their rims in ashes, leaves or soil on a cool base. Re-pot the plants early in July.

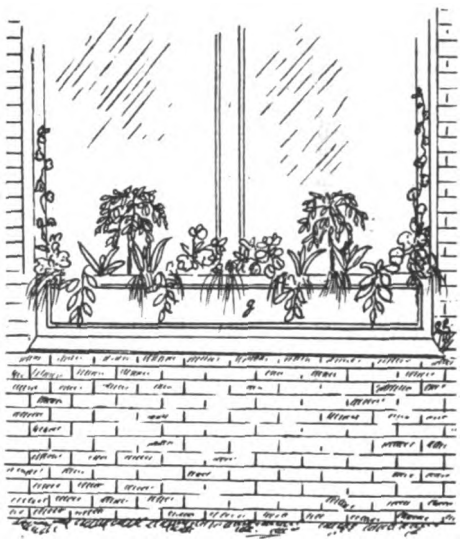
THINNING-OUT SEEDLINGS.

This is work that takes up much time, but it is a very necessary one if the slugs have not been too busy. They generally take the best seedlings or all of them. I thoroughly enjoy thinning-out healthy young plants and endeavour to begin the work at an early stage of their growth and strongly advise readers of THE GARDEN to do so. When the seedlings are small they possess only a few roots and so the majority can be drawn out without interfering with the roots of those left in the rows. Suppose we take, for example, a bed of carrots; if the thinning has been unduly delayed, the plants retained are much loosened in the soil, the carrot fly can easily do its worst, as we often see when the matured roots are lifted and their skins marred. Always look out for the isolated seedlings—those growing, perhaps, 1in. from a cluster of seedlings—and retain the isolated specimen in preference to one in the bunch. The same remark applies to turnips, beet, onions and annuals. Place a finger on the soil near the one to be left in the ground and gently press it to prevent that seedling being disturbed. When the work of thinning is finished, we possess the right number of seedlings in each row, and so we must take care of them and protect them from slugs. A few old ashes washed by rains, should be scattered round our most cherished annuals, as slugs do not crawl freely over sharp ashes. Water through a fine-rosed watering can to settle the soil round the seedlings left. The evening is the best time to do the work of thinning-out.

WINDOW BOXES.

These, well and tastefully filled, make a beautiful house still more beautiful, and even commonplace ones attractive. In certain positions the window boxes are sheltered, but, generally, they are exposed to cold and sometimes strong winds.– It is a mistake to place plants in a window box and the latter in the window





forthwith, except in certain cases and at mid-summer time. The best way is to get the plants established in the boxes during the latter part of May and then place the boxes in the windows about June 10th. Of course, I am referring to outside boxes. The latter, while the plants are being established in them, should be placed in frames or in cosy corners, where temporary shelter may be afforded during the night time and on very cold days. The old combination of scarlet zonal pelargoniums, white marguerite, daisies and blue lobelia is very satisfactory in many cases. But annuals may be used to great effect, and ferns and fuchsias, also begonias in boxes, placed in windows receiving very little sunshine. For hot positions, petunias, antirrhinums and nasturtiums, with Gazania splendens, are most satisfactory. Some holes, *a*, *a*, should be made in the bottom of each box, and cross pieces, *b*, *b*, attached to prevent warping. The window stones have a sloping surface, and if boxes are made square in shape, *c*, they should have wedges, *e*, under them. If the boxes are made to fit the stones, as shown at *d*, wedges are not required. Sections of stones shown at *f*, *f*, and the box in position at *g*.

TREATMENT OF SEEDLINGS OF PERENNIALS.

The treatment during their young stages of growth has much to do with the later successful flowering of the full-grown plants. With a few exceptions, hardy border perennials, to which I am now referring, grow freely enough, and so they are allowed to exist instead of being cared-for as valuable plants, which they really are. There is a vast difference between herbaceous borders properly attended to and those that are neglected. The amateur should select some nice open border in the garden and devote a few square yards to the seedlings and quite young stock. When the time comes to re-arrange the herbaceous border or to plant the new one, he will be glad that he did look after the youngsters. Take, for instance, the seedlings of the Michaelmas daisies; they are very interesting, and one never can tell beforehand how many gems one will cull from the collection. If the soil is poor and shallow, dig in some fresh loam, leaf-soil and rotted manure. Allow the soil to settle for a week or ten days before the young subjects are planted in neat rows and duly labelled. It is better to plant when the soil is dry than when it is wet and sticky; but a good watering should be given directly the work of planting is finished. Make the soil firm around the seedlings with the fingers while engaged in planting. Some kinds require shading a little, and, as the quarter is an open one, the necessary shading can be afforded by sticking in a few evergreen branches. Slugs do a lot of damage, especially to delphiniums, Lobelia cardinalis, lychnis, pyrethrums and dianthus. Fine, washed cinders are effective, also lime and soot judiciously used.

ANNUALS FOR LATE FLOWERING.

Half-hardy and hardy annuals are eagerly raised early in the season with a view to having an early display of flowers. If the slugs and other untoward circumstances permit, the display is usually forthcoming; but in many instances it is short-lived, and then seared plants or bare patches result. The usual early plants are now in need of thinning-out, so readers should sow more seeds now of the following, chiefly stocks, night-scented stock, clarkia elegans, godetias, Shirley and double-flowered poppies, lupins, mallows, mignonette, candytuft, marigold (pot) and dimorphotheca. A good method of sowing the seeds is as follows: if the seeds are to be sown in beds of mixed flowers, make circular shallow drills with a pointed stick, sow the seeds, cover and label. GEORGE GARNER.

GARDENERS: II—THE SPECIALIST

SPECIALIST gardeners appear in every course of life; some are born specialists, some are made specialists and some have specialisation thrust upon them. Many people laugh at the born specialist and strongly object to being forced to take an interest in seedlings or unflowered specimens of a plant they do not know; but the people who specialise in daffodils or rhododendrons are only the obvious specialists; there are hundreds of others working in the background to whom we owe most of the plants to be found in our gardens.

There are specialists who rarely enter a garden and yet have a great influence on modern gardens; there are the plant biologists and the plant pathologists and other members of the botanical fraternity. There are specialists who do nothing else but raise new sweet peas or new roses or some other garden flower; these sit in a seed farm or in a nursery and are only known by name to a chosen few. There are specialists who can work wonders with a cutting or a bud or a graft and who think nothing of making thousands of grafts in a month. Trade secrets, you may say about all of these. No, emphatically no. Tricks which can be learnt by anybody provided that he is prepared to go through the mill and spend years in learning how to do one job in two minutes, a job which would take an ordinary mortal an hour. These are the drones in the horticultural hive. They live and die unknown, but no one can deny that every garden owes a great debt to their labour. These are they who have specialisation thrust upon them. They must be specialists in order to make a living.

Made specialists are different. Either they garden or they work as ordinary gardeners. There is no necessity for them to specialise and yet long practice or nimble fingers or some little, and possibly easily acquired, knack has made them perfect in one particular thing. Climate or soil conditions may have a great deal to do with their special subject. A perfect soil for roses will usually end in making the gardener a specialist in roses. It makes him go beyond the actual needs of his job. He will read up the subject; he may try his own hand at making new varieties; at any rate, it will carry him beyond the knowledge possessed by the ordinary gardener.

The born specialist is unexplainable. A virus infects him; he has a craze for growing a certain genus or for cultivating a certain type of garden. So severe is this disease that one might say he is not a gardener at all. It is the collector's craze which may attack anyone who has a hobby for collecting anything, whether it be plants or stamps or policeman's batons. Often it is incurable, sometimes the attack slackens in its intensity, usually from a surfeit of good things or from lack of space. I may as well be frank and say that I suffered from a severe bout of rhododendronitis, but, although I like them as well as ever, the intensity of my passion waned when I found that several thousand acres would be necessary to grow every rhododendron in the way I should like to see them—in mass formation of anything from twelve to a hundred plants of each of the seven hundred species, apart from hybrids. I have given up collecting rhododendrons. I now pick and choose those which I think I like or which I consider will grow well in my garden. Consequently, I have room for other plants and my outlook has widened considerably.

There must be a great deal of the gambler in the born specialist, for he is never so happy as with a new find. However doubtful the description of a species or however small the chances of a masterpiece in a batch of hybrids, he will tend them as carefully as his greatest treasures, though it may be years before they flower. Born specialists are nothing if not courageous.

Lest I be considered a renegade I will admit that I would specialise again to-morrow, if I could discover some good-looking genus whose members were limited to twelve or so in number with an added guarantee that not more than two new hybrids and two new species were to be introduced every year. It is the unknown that terrifies me and although I confess to being a collector, it is very much a case of once bitten, twice shy.

And yet our gardens have a great deal for which to thank the born collector. Who else would there be to test and report on new species and new varieties, particularly of trees and shrubs? The botanic gardens can never grow them all, the ordinary gardener has not the requisite keenness, and there is too much risk attached for the nurseryman to attempt it, even if he had the staff and the space. Somebody has to do it, else horticulture would languish, so even the born specialist has his uses.

HYDRANGEAS

THE great variety of colour to be found in the new introductions of Hydrangea hortensis have made this class of greenhouse plant extremely popular in gardens, and rightly so, considering the comparative ease with which they may be cultivated. The flowers last a long time, and hence their value for the decoration of the conservatory and greenhouse.

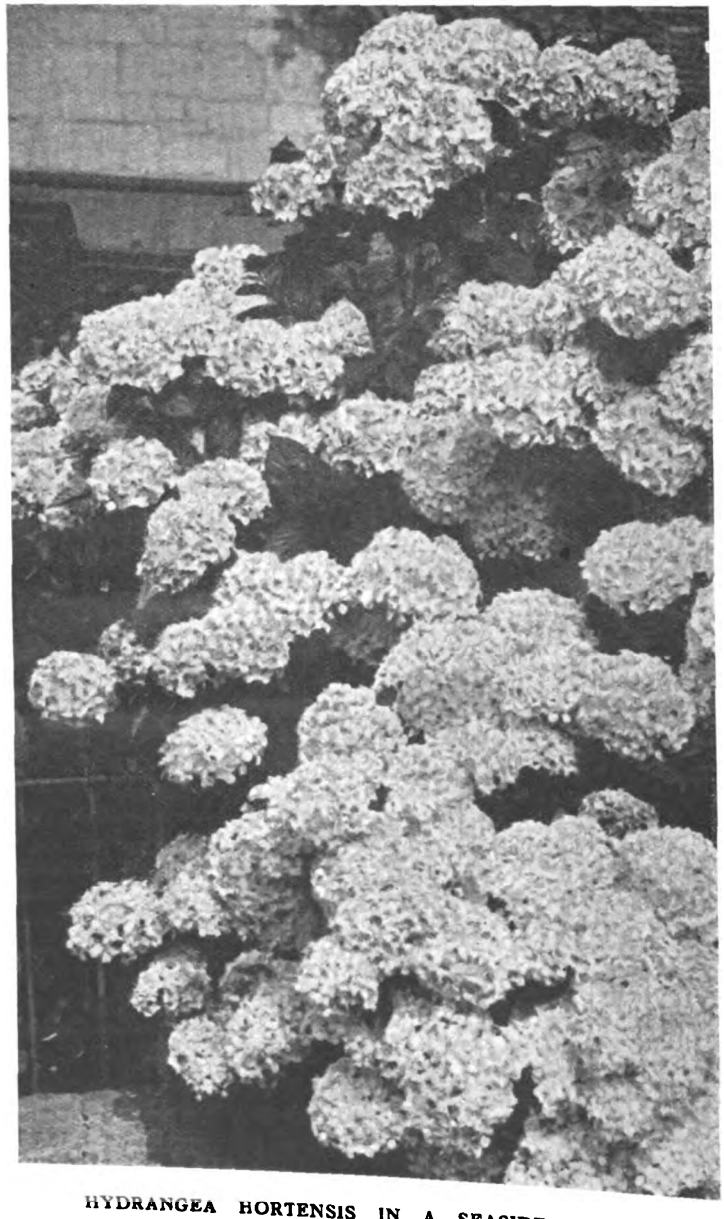
For house decoration they are also admirable, the flowers lasting considerably longer than many other flowering plants. Several nurserymen have of recent years made a speciality of hydrangeas, notably Mr. H. J. Jones of Lewisham. Magnificent groups have been exhibited from time to time at the Chelsea and other shows, which have impressed visitors, and especially gardeners, with the great advance in size of the flowers, the beauty of their colour, and variety. Some of them have received awards of merit from the R.H.S., testifying to their fine qualities.

Hydrangeas may be cultivated in various ways for different requirements. They may be grown with single stem, carrying a large head of bloom, in 48-size pots, or larger plants with several growths in 32 and 24-sized pots, up to specimen plants in 10in. and 12in. pots, according to requirements. Large specimens in tubs make a fine display during the summer months, when standing in conjunction with other plants on terrace walks, where they show to excellent advantage. For this purpose choose those of a strong, sturdy habit of growth.

Propagation may be effected by two methods—either by taking cuttings of the young side growths off the older plants in the spring, or by half-ripened growths during August and September. Personally, I prefer to propagate at both seasons, thereby ensuring a good stock of young plants. Where stock is plentiful, several cuttings may be rooted in each pot, and later again potted into a larger size, without division, thereby ensuring a larger flowering plant in the minimum space of time.

For autumn propagation, good strong shoots should be selected, preferably those which failed to flower during the summer months; in these shoots will be found a good plump terminal bud, which will, if all goes well, give a large head of flower in the following spring months.

The cuttings should be inserted singly in small pots—using fine light soil with a liberal amount of silver sand—well watered in, and placed in a warm close house till rooted, shading from strong sunshine. When the cuttings are rooted they must be at once inured to cooler treatment until they are eventually rested in a temperature of from 35° to 40° Fahr. during the winter months, affording free ventilation whenever the external conditions permit. Water must be used sparingly during the resting period, but excessive dryness at the root must be avoided in these young plants.



HYDRANGEA HORTENSIS IN A SEASIDE GARDEN.

An early peach house or vinery is a good place to start them gently into growth, potting them on into 48's as soon as growth is apparent; in this size they will flower, giving one large head or corymb of bloom, and will prove very popular for house decoration.

Give plenty of water and feed the plants during active growth, until the flowers begin to expand, when feeding must be gradually discontinued. Discriminate in the use of the shading, as the flowers will not stand much sunshine early in the season when grown under glass,

Plants two or more years old may be kept well on the dry side during the resting period, in cold houses or frames from which severe frost is excluded, and brought in in batches as required, to keep up a succession. In this manner hydrangeas may be had in flower from spring till September. Certain varieties respond to slight forcing more readily than others, notably that fine white variety, Mme. Mouillere. I have found this variety to differ somewhat from others of H. hortensis, in that it may be had in flower both earlier and later in the season by propagating at different times. Given a sufficient number of plants, it is possible to have this variety in flower eight or nine months of the year. From cuttings struck in August they have flowered in 60-size pots during November and on into December, giving nice useful heads of bloom. Again, from plants started in January they may be had in flower in April.

I have in my mind's eye a pair of specimen plants that were grown on from plants in 48's purchased in the summer of 1922; in the following May, 1923, they flowered splendidly in 24-size pots, having a dozen or more good heads each. Resting them, and again potting them on into 11in. pots, starting them in January in gentle heat, these plants in the following May carried, each, thirty to forty large heads of flower, pure white, averaging 3ft. high by 4ft. through, and being perfectly symmetrical in shape. I merely mention this as an illustration of what may be done in a year or so with hydrangeas.

Two very distinct and beautiful forms of blue varieties of hydrangea are Mariesii and involucrata. Both of these have fertile flowers in the centre of the corymb, with a row of sterile flowers round the outer edge, which considerably enhances their beauty.

Another distinct variety, seldom seen, is H. Sargentii, with flowers similar to the above, except that the very large corymbs are creamy white in colour. This species differs in many ways from H. hortensis. The growth is hard-wooded, erect in habit, with large leaves (not unlike those of a stove plant, Cyanophyllum magnificum), with a velvety sheen, and veined; the leaves will not bear exposure to the sun without being considerably scorched and disfigured, but grown

Digitized by Google

shaded intermediate house it forms both a unique and very decorative plant, in my opinion the foliage being far more beautiful than the flower. Anyone who has hitherto failed with this variety will find it to prove satisfactory grown in the manner described. Many varieties of hydrangeas are hardy, given suitable soil and positions, seeing that they come from various parts of the world—America, China, Japan. Of these, mention may be made of some of the most interesting: arborea grandiflora, quercifolia (the oak-leaf form), vestita, involucrata, paniculata grandiflora, and others. The last-named is largely used for forcing in pots, and requires to be pruned back annually, flowering as it does on the current season's growth, in large white panicles. It is also one of the best for outdoor cultivation: in this case the pruning should be done in March.

There is a climbing variety named scandens, suitable for walls and clothing the trunks of trees. It is self-supporting, after the manner of ivy, and bears white flowers. There is another variety of hydrangea I had almost forgotten to mention —cyanoclada, with jet black stems, which always proves interesting, either in or out of flower, on account of its uncommon colour, in a collection.

Hydrangeas will be found to thrive in the following compost: Three parts good fibrous loam, one part peat, one part old mushroom-bed manure, a little soot and some crushed charcoal, adding a 48-size pot of bone-meal to the bushel of soil: mix well several days previous to use, and pot moderately firmly.

Hydrangeas must have a season of rest. After flowering they may be placed on a bed of coal ashes, in full sunshine during the autumn months. Any pruning may then be done, at the same time potting on any plants requiring it. As the season advances, watering may gradually be decreased until the foliage falls, when they may be wintered in the cold houses or frames. The following list of good varieties of H. hortensis can be recommended: Mme. Mouillere, Lilie Mouillere, Germanie Mouillere, Parzival, La Marne, Brilliant, Triumph, Mariesii, Helge, Lorley, Krimhild, Mme. H. Hamar; these constitute a good dozen for pot culture.

AS DECORATIVE SHRUBS HYDRANGEAS ARE EXCELLENT BOTH FOR FOLIAGE AND FLORAL EFFECTS.

With reference to the colour of the blue in hydrangeas, what is needed are decided colours, such as an Oxford and a Cambridge blue. A good clear pink is far better than a muddled between colour, which is neither beautiful nor effective.

I. HAWKES.

GARDENS OF HEALING.—I

GARDENS of healing, that is, those given over to the cultivation of medicinal herbs, are rarities in Britain. On the Continent they are frequently found both in private and commercial grounds. Such gardens are both interesting and remunerative, and all owners of a bit of spare ground would derive much pleasure and profit if they turned it into a medicinal garden of plants with healing properties.

The work which requires the greatest care in this connection is that of drying the herbs. They should be handled as little and as lightly as possible and never crushed. Trays, such as apples are stored in, should be used. All plants are best dried in the sunshine, but if that is non-existent a room heated by pipes, such as a warm greenhouse, or close to a wall where the heat of the kitchen range is felt, or even a very slow, moderately heated oven will dry the plants efficiently. With very few exceptions all heat other than that of the sun should be slow.

The size of the health garden varies, of course, according to the amount of ground at the owner's disposal. It should be divided off by little paths, around and between the plots, in the manner of French kitchen gardens, in order that every part of the bed can be within reach of the gardener's hands, and thus the ground is never trodden on. Each plot should have a large, distinctly marked label at its top right-hand corner, and should be kept constantly hoed and entirely free from weeds.

ROMAN CAMOMILE (Anthemis nobilis).—Roman or double camomile is one of the most important of medicinal herbs. It is also one that requires the least care in cultivation. It will not grow in heavy land or in wet situations, but likes a hot, dry soil rich in *silica et voilà tout*. Camomile loses none of its properties by desiccation.

The stinking camomile (A. colutea), which is almost as ubiquitous as the common groundsel, possesses all the qualities of its rich aristocratic relation, but in a markedly less degree.

The healing virtues of A. nobilis are recognised and made use of all over the world, but in our country the plant is not so extensively grown as it ought to be, although it is in constant demand. The flowers cost 7s. 6d. per pound, and are obtained from the Continent, where every garden, large or small, private or commercial, has its camomile border or patch. In both North and South America large tracts of land are given over to the cultivation of this herb.

In France *tisane de camomile*, or camomile tea, is *de rigueur* after an indigestible meal, and it is used medicinally as a digestive, a tonic and a safe medicine for all intestinal and stomachic disorders, and also as a febrifuge.

This infusion is antiseptic, and its application quickly cleanses and heals all wounds, ulcers and running sores. For this purpose quarter to half an ounce of the dried flowers are steeped in a pint of boiling water and allowed to "draw" like tea. Camomile infusion should *never* be taken internally after it has been infused for over half an hour.

For children suffering from rickets or eczema hot baths in which half a dozen camomile heads have been thrown are both soothing and health giving.

Finally, camomile oil is invaluable for all rheumatic and internal pains if applied *externally*. It is obtained by allowing 3 oz. of the tops of the plant to simmer for two hours in a pint of olive oil.

ANGELICA ARCHANGELICA.—Nature we know grows plants for the cure of diseases

Digitized by Google

to which animals are subject, and eminent naturalists have recorded many instances of birds and beasts doctoring themselves and their offspring by eating various plants. A notable example is that of the partridge of North America, which gives her little ones the partridge berry to eat when they are out of sorts.

Dogs and cats, as everyone knows, have recourse to the beneficent virtues of couch grass when they feel unwell. It seems only logical to conclude that cures for man's bodily ills are to be found also in the vegetable world.

Angelica Archangelica, known also as the Root of the Holy Ghost, received these celestial names on account of its real or imaginary virtues. In very early times all its parts were considered efficacious against witchcraft and enchantments, and in the Middle Ages it was the sovereign remedy against poison, the plague and all infectious maladies. Nowadays it is used daily on the Continent for indigestion, general debility and chronic bronchitis. For external use the fresh leaves of the plant are crushed and applied as poultices in lung and chest diseases.

The roots of angelica should be dried rapidly and placed in air-tight receptacles. They will then retain their medicinal virtues for many years.

A delicious liqueur which is also a digestive, preserving all the virtues of the plant, is made in this way: 1 oz. of the freshly gathered stem of angelica is chopped up and steeped in 2 pints of good brandy during five days, 1 oz. of skinned bitter almonds reduced to a pulp being added. The liquid is then strained through fine muslin and a pint of liquid sugar added to it.

The natural habit of angelica being the banks of streams and ditches and shady woods, it is evident that the plant must be given a shady situation in the health garden. Seeds of angelica are sown in the spring, and as the plants are very large, they should be thinned out to at least a yard apart.

PIMPINELLA ANISUM (Aniseed).—The virtues of this umbellifera are analagous to those of the angelica and are found chiefly in the fruits of the plant, from which a very aromatic oil is extracted. A liqueur known in France as anisette is made by steeping pimpinella fruits in brandy for a month or more. This is constantly used for chronic indigestion and flatulence. A very pleasant tooth-powder which strengthens the gums and whitens the teeth is made by mixing powdered pimpinella seeds with equal parts of charcoal and cinchona bark.

Aniseed likes a rich, damp soil and a south aspect. Seeds should be planted in March, April or May and the plants thinned out to 18ins. apart.

VICTORIA SLADE.

SUMMER BEDDING

AT THIS SEASON OF THE YEAR THE SUGGESTIONS PUT FORWARD IN THIS ARTICLE SHOULD PROVE OF ASSISTANCE TO THOSE WHO MAY WISH TO GET AWAY FROM THE ORDINARY STEREOTYPED BEDDING OUT DESIGNS AND SUBJECTS.

DAME FASHION plays her part in gardening, and perhaps in no section has she proved herself such a fickle jade as in the furnishing of that part of the garden where beds are annually filled with spring and summer bedding plants. This applies more strongly to summer bedding than to spring bedding, owing, no doubt, to the greater variety of plants suitable for the former scheme. One has to go back many years when "carpet bedding" held sway, and owing, perhaps, to the novelty of the design rather than to its beauty, it arrested attention and aroused a feeling of curiosity. This in time changed to the massing and ribbon border fashion. Such plants as pelargoniums in variety, calceolarias, petunias, verbenas, lobelia and pyrethrum were used lavishly, and in many gardens the glasshouses were severely taxed to provide sufficient plants to meet the demand. This somewhat formal style changed after a considerable run of popularity to what may be termed the "mixed, or dot, system." This was done, and still is to a great extent, by using various dwarf-flowering or foliage plants for massing, with the addition of taller, graceful foliage and flowering plants, not too thickly, to break the stiffness. This system entailed much work and expense and has, of necessity, practically gone out of fashion.

ANTIRRHINUMS IN A PARTERRE.

In many large private gardens the section devoted to summer bedding has of late years been modified, or in any case plants are now used which are less expensive to prepare than was previously the case. In others, where the position of the beds permits it, roses and other hardy plants have been substituted. Though hardy perennials cannot, perhaps, be substituted which will give the same freedom and prolonged display of bloom as many of the typical bedding plants, many combinations of plants can easily be thought out which would give fairly satisfactory results. For instance, beds carpeted with either violas, nepetas, pinks or arabis could have such plants as astilbes, liliums, gladioli, galtonias, montbretias or campanulas planted among them. Beds also of pentstemons (pale pink) and Eryngium Oliverianum, Anchusa italica Dropmore variety and Œnothera biennis — Anchusa, Delphinium Bella Donna and Salvia patens — Potentilla Gibson's Scarlet, Sidalcea Listeri and montbretias or Lilium tigrinum—Violas, aquilegias and Veronica spicata—Phlox suffruticosa Victoria and Pentstemon Chester Scarlet or Middleton Gem would all bloom for the greater part of the summer and, of course, be economical to use.

That there is no falling off in public taste for typical summer bedding is, however, fairly certain. Evidence of this is that the sale of bedding plants has probably never been greater than it is to-day.

It is, fortunately, a trait of an English home, of whatever size, that there must be some flowers surrounding it during the summer. Plants to use and the scheme of planting should be governed somewhat by the design of the flower garden and its

Digitized by Google

proximity to the residence. The material also with which the residence is built should have more consideration than is sometimes given it. Who has not seen the dazzling scarlet Pelargonium Paul Crampel planted in front of one of the crude brick houses which are now springing up on all sides and shuddered at the sight? How much more pleasing would the effect be with flowers of light blue and lavender, such as Viola Maggie Mott, ageratum, Aster sinensis, heliotrope and Plumbago capensis. An effective plant, too, for such a position is that charming little Dahlia Little Othello, with its dark metallic foliage and crimson blossoms. This plant, which rarely exceeds 18ins. in height, is not as well known as it deserves to be. Lemur is similar. I prefer either of these varieties to the popular Coltness Gem, and I know many who have seen them agree with me.

The older red brick house which has been toned down with age should have the association of flowers of dull orange, apricot and salmon or coppery crimson. Suitable plants for providing these colours are readily found in the charming nemesias, begonias, antirrhinums and calliopsis. What a beautiful little annual the nemesia is with its wide range of colouring! I doubt if it has an equal as a dwarf annual, useful alike for beds and pots.

A white house, somewhat rare perhaps, may be surrounded by flowers of rather bright hues, such as vermilion, blue, bronze and amber. These colours are found in many plants. A few are antirrhinums, begonias, Delphinium Blue Butterfly, Salvia patens and cannas. The latter, especially the varieties with bronze foliage, are striking.

A grey stone building provides a setting for almost any colour scheme.

Even when the flower-beds are not sufficiently near the residence to affect the colour scheme, they are usually under continuous observation, as distinct from a seclusive garden. It is therefore necessary to use plants as far as possible which will provide a long season of blooming. Where the beds will be continuously viewed close to the eye, and particularly if not on a large scale, a soft harmonising effect will be better than that obtained by boldly contrasting colours. For real beauty delicate colours are undoubtedly best, such as shades of pink, mixtures of pink and white, light blue, straw-coloured yellow, apricots and salmons and soft tones of crimsons. Strong colours may be rich and showy in contrast, but are less beautiful and hardly in such good taste. Where, however, the scheme is a large one with long stretches of beds, strong contrasting colours toned down with graceful foliage plants would be best. Where a bed or group of beds is to be viewed from a distance, an effect should be aimed at which will appear full of expression. Some of the bright begonias, pelargoniums, salvias, antirrhinums and dahlias suggest themselves.

In arranging foliage plants with the flowers the colour of the foliage should be considered in proportion to the intensity or delicacy of the flowers with which they are mixed. The brighter the flowers the stronger should be the green of the foliage, and the more delicate a corresponding softness. The same proportion should be observed with regard to the habit of the foliage plant. A heavy, bold foliage plant, such as a ricinus, would be sadly out of place over a carpet of nemesias, whereas a few might be permissible over large-leaved begonias and ideal over a thin planting of a dwarf canna. Useful foliage plants are abutilons, eulalias, Grevillea robusta, Acacia lophantha, Gnaphalium microphyllum. When used, the object of such plants is to relieve, not to hide, the carpeting plants.

Many beautiful flowering plants may also be used with great effect as relief plants. Thoughts immediately turn to that delightful old plant Plumbago capensis, which greatly enhances a bed of blue verbenas or violas such as Maggie Mott. Lantanas are favourites of many, and can be grown in various shapes, such as pyramids or standards, and look well over a carpet of Verbena venosa or white antirrhinums. Plants can also be pegged down to form a carpet for the taller plants. Heliotrope is always popular and lends itself for use much in the same way as the lantana, and has the added charm of scent. Another plant of a more striking colour is Streptosolen Jamesonii. This makes an effective bed with a carpet of white or yellow violas. It may also be happily associated with warm apricot antirrhinums, orange begonias or Coreopsis grandiflora. A beautiful effect is obtained by a mixture of Delphinium Blue Butterfly and white antirrhinums.

TUBEROUS BEGONIAS AND FUCHSIAS ARE ADMIRABLE FOR BEDDING PURPOSES.

Few subjects are more attractive than Fuchsia Coralle. There are several similar varieties, all hybrids of Fuchsia triphylla. They are excellent for bedding, and if given a fairly rich soil and sufficient moisture make splendid plants which bloom profusely for months. A carpeting of a good white viola would intensify the pleasing coral colour of the fuchsia. Lobelia cardinalis rising through a carpet of the grey-leaved Cineraria maritima is striking. The use of the dainty grey-foliaged plant Leucophyton Brownii as a carpet and a few staked up as relief plants among pale pink begonias is an oft-repeated but always pleasing combination. Calceolaria amplexicaule is an old plant, but its pale lemon flowers are always permissible. It can be used in various ways, either as a tall plant among dwarf subjects, or it will be equally useful as a foil for taller flowering plants or foliage.

Frequent mention has been made of antirrhinums. The selection is endless in colour and in various types from dwarf to tall. They are probably used in greater numbers than any other class of plant.

The dwarf scarlet Dahlia Coltness Gem has largely superseded Pelargonium Paul Crampel as a bedding plant, and rumour has it that there are not enough plants to meet the demand this year. There are, however, many other good varieties. Mention has already been made of Little Othello and Lemur. Those partial to a small cactus dahlia should try René Cayeux. The plants rarely exceed more than 2ft. in height, the habit is graceful and the flowers a dazzling crimson scarlet. Marianne, a dwarf plant with warm apricot-coloured blooms, will be sure to please if planted in soil which is not rich. It is now classed as a camellia-flowered dahlia. Some of the specialists list quite a lot of varieties of the Mignon type, all of which are dwarf and ideal for bedding. For larger beds and taller effects up to 3ft., the popular miniature-flowered peony type cannot be too strongly recommended.

Ivy-leaved and Cape pelargoniums and many annuals not mentioned are excellent when used in the proper place.

These are only a few ideas and could be extended indefinitely. Summer bedding may not be regarded in such an important light as it was some years ago. Nevertheless, in carrying out a scheme, whether large or small, the aim should be to get an effect which will be bright but not gaudy, appealing yet restful, and the arrangement such that it represents a work of art.

ARTHUR J. COBB.

SWEET-SCENTED ALPINES

FRAGRANCE IS ONE OF THE MOST VALUED ASSETS IN THE ROCK GARDEN, AND A FEW OF THE ALPINE SUBJECTS MENTIONED IN THIS ARTICLE SHOULD BE INCLUDED FOR THEIR PERFUME AS WELL AS FOR THEIR BEAUTY OF FORM.

THE voice of the multitude is unanimous that a sweet perfume should weigh very largely in the estimate of all flowers; and the absence of scent, characteristic of most alpines, and nearly all high alpines, does a disservice to the rock garden. The fewer the rock plants that are scented, therefore, the more should they be singled out for mention and for attention to their cultivation. Yet, now that I have racked memory and books for alpines notable for their perfumes, their number is not really exiguous. On the hills Thymus Serpyllum charms by its yard-wide mats of large-headed floriferousness as well as by its scent, and the rock garden would gain by the inclusion of its numerous varieties—lemon, or caraway, or camphor, or just "thyme." On the hills one takes in wide-open lungfuls of honeyed breaths of Trifolium alpinum, and why not in the garden, be the clover never so humble? But of alpines more august than these my notebook has now many pages of names; and in the first instance I would write of those which fill the mountain-sides with their ubiquitous fragrance.

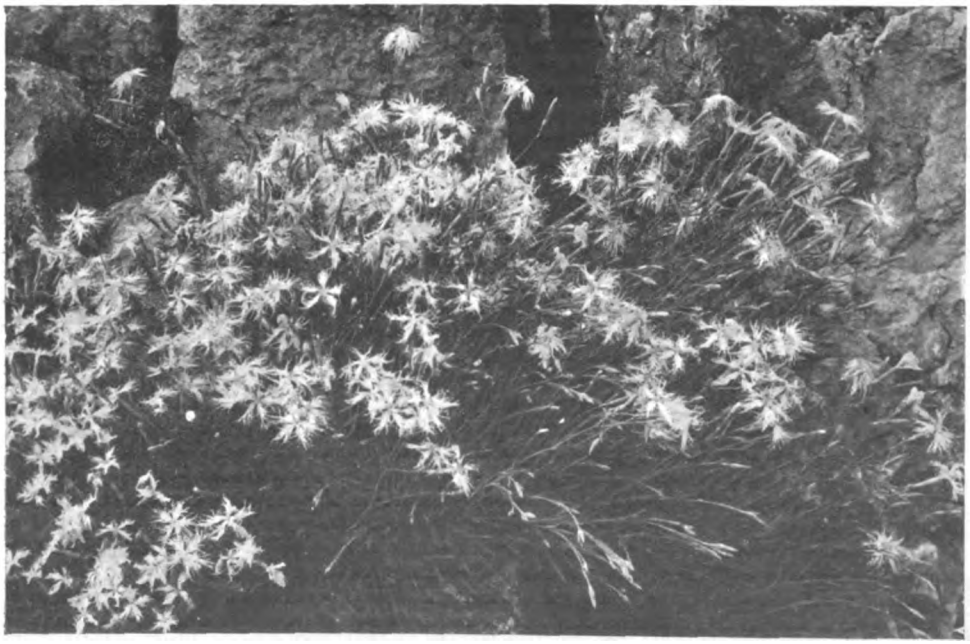
Two memories take first rank: one, the high upland pasture that lies immediately behind the Pordoi Hotel in the Dolomites at about 8,oooft.; the other, the stony sunburnt slope not much above sea level that rises from Torbole towards the sky-high peak of Monte Altissimo di Monte Baldo. Wherever you roam, the exquisite fragrance of Daphne striata haunts you on the one, and of Dianthus monspessulanus on the other; while on both, the nose in advance of the eye tells you that the daphne or pink are around—blessed the alpine that proclaims its vicinity by its perfume!

On the Pordoi and in the Val del Fain on the Bernina the daphne makes charming ground-hugging hummocks, and its colour when young is a good rose-pink. Strictures have been passed on striata, and panegyrics lavished on Cneorum; but sight and scent on the Pordoi make you sensible that you would not love the one so much did you not love the other—just as much. The rare rupestris, the less rare alpina and Blagayana, and the common but dull-flowered and lanky Mezereum are all of high value for their scent alone, while rupestris ranks among the most beautiful of all alpines.

Dianthus monspessulanus, on stony slopes above Torbole or rioting in fields along the Val di Ledro as poppies do at home—turning into pinks and poppies what was meant for corn—has close relationship with the well known D. superbus. But whereas superbus is a tall straggly single plant of woodlands (as in the woods of sils in the Engadine, most beautiful, second only to Misurina, of all alpine woods), monspessulanus forms tight tufts a foot or two square, a foot in height, in full sun on scree or field, with lavender blossoms, darkly mottled (or all white) equalling in number the garden pink. The higher form of monspessulanus, called D. m. Sternbergii, not more than 6ins. high, is found on the higher slopes of Monte Baldo and also just below the precipices at the back of the Faloria Hotel at Cortina, and again on the stony lawn in front of the hotel at Tre Croce, half-way between Cortina and Misurina. There is also a high alpine form of superbus, called speciosus. Of the exact relation between these forms I am unaware, and it is sufficient to say that DD. speciosus, superbus, Sternbergii, monspessulanus, squarrosus and, perhaps, plumarius, are subspecies of D. fimbriatus, the fringed pink. All are invaluable for their sweet pervading perfume, and whereas superbus fails of being truly perennial, the higher, dwarfer and neater species have no such adverse reports.

The valerians must be the last to be included at present. The tiny valerians—celtica, the ancient Nard, smelling of patchouli;

THE LARGE SPREADING MATS OF THYMUS SERPYLLUM CLOTHED WITH MYRIADS OF TINY SCENTED FLOWERS.



DIANTHUS SUPERBUS, QUAINTLY FRINGED AND DELICIOUSLY FRAGRANT, IS ONE OF THE MOST CHARMING OF SWEET-SCENTED ALPINES.

Digitized by Google

elongata; globulariæfolia; salinuca and tripteris, are valuable for their intense sweetness alone, their tight little spikes of dingy flowers reckoning not at all. The jewel is the almost stemless V. supina that unites inimitable fragrance with wide mats of distinct and clear pink flowers. Alas! that supina haunts the wild cauldrons that cleave the southern elevation of the Schlern, up from the Ischamin-thal near Bozen, where you mount the precipices by ladders and Baedeker warns you of "inconvenience to those subject to giddiness." If I had to ascend a precipice by a ladder, it is not Valeriana supina that I would be looking for; and as giddiness belikes me not, I regretfully conclude that supina is in no danger of extirpation by me and must continue to waste its sweetness on the mountain air. E. E. T.

TWO ORNAMENTAL PLANTS

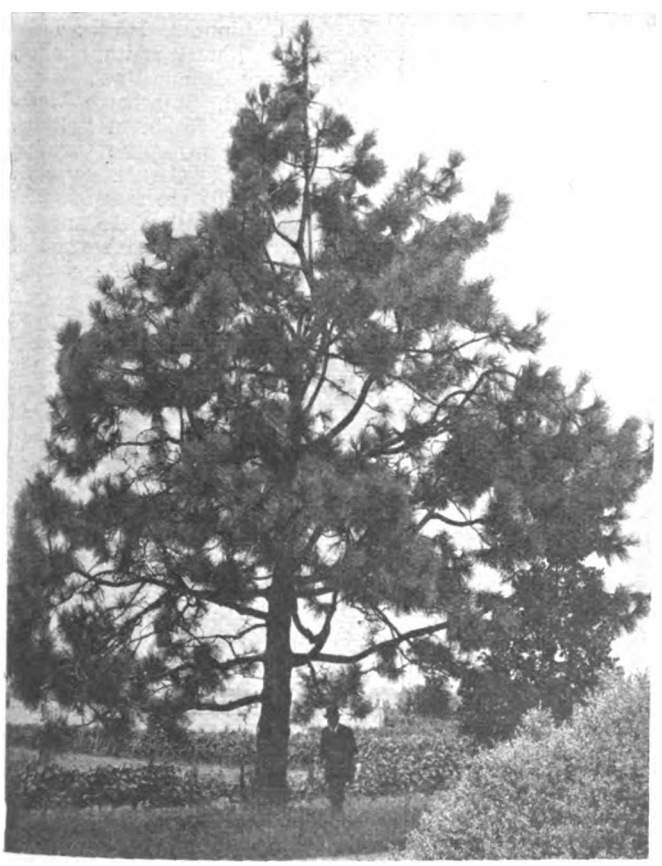
PINUS JEFFREYI.

THE Californian black pine, in its native home also called truckee or sapwood pine, according to Britton has rather often been planted on the Continent. One of the best specimens I have met with stands on the small island Scharfenberg at Tegel, near Berlin, in the once famous collection of Dr. Bolle. Quite a number of good plants can be seen in private gardens in western Germany, for instance, along the Rhine. It has been tried rather successfully as a forest tree in the same way as P. ponderosa, the bull pine, of which P. Jeffreyi is often regarded as only a variety. According to Jepson, the well known author of the Californian flora, P. Jeffreyi merges insensibly into ponderosa, but there may be intermediate forms of hybrid origin. For horticultural purposes it may well be regarded as a good species, differing from ponderosa in its distinctly glaucous young shoots, its hardly resinous buds, its somewhat stiffer pale bluish-green leaves, which measure only from 4ins. to 8½ins. in length, and in its larger, usually purplish cones which are up to 12ins. long. If one breaks a young shoot it smells strongly of oranges, while the young growth of ponderosa has a peculiar smell of turpentine. The illustration shows a fine plant of P. Jeffreyi from the late Mr. Allard's famous collection of conifers at La Maulévrie, near Angers, in France. The old gentleman, one of the keenest collectors and finest men I have ever met, is seen standing under the tree. He had brought together an exceedingly rich collection of broad-leaved evergreens, too. The arboretum belongs at present to the Institute Pasteur at Paris.

With its large cones P. Jeffreyi forms one of the most interesting species of the genus pinus. It has proved hardier on the Continent, as one might expect from its habitat. According to Britton it occurs on dry volcanic mountains from southern Oregon through Calfornia to lower Calfornia, often forming pure forests. In the most favourable situations it occasionally reaches a height of 230ft.

RUBUS BIFLORUS VAR. QUINQUEFLORUS.

Among our European representatives of the genus rubus there are, in spite of the enormous number of so-called species, very few distinct types. It is China, the dendrological paradise that sends us the most striking and ornamental types of this genus, too. Take, for instance, such semi-evergreen or evergreen species as R. Henryi (R. bambusarum), R. chroosepalus or R. flagelliflorus. But of a very different aspect are the deciduous R. Giraldianus and the one I wish to speak of at present, R. biflorus, in its Chinese variety, quinqueflorus. The illustration shows at once the striking effect of a vigorous plant. I took the photograph in the garden of Count Herbert Schaffgotsch at Purgstall, Lower Austria, where this keen and enthusiastic amateur has brought together a surprisingly rich collection of rare plants. I shall speak of his fine rock garden later on. Among the woody plants of his collection this Chinese raspberry is of a peculiar interest. The typical R. biflorus is a native of the Himalaya, and has already been introduced in 1818, but never became very well known, at least in the gardens of the Continent. In 1907 Wilson



THE CALIFORNIAN BLACK PINE, P. JEFFREYI.

A FINE CHINESE RASPBERRY, R. BIFLORUS QUINQUEFLORUS

Digitized by Google

made us acquainted with the Chinese form that seems to be a more vigorous and much hardier plant. Its strong shoots reach a height of more than 13ft., and are covered with a beautiful white waxy bloom, and armed with straight prickles. As Bean has already stated, during fall and winter a group of this raspberry makes one of the most striking plant pictures in the open air. There are two other Chinese species with similar white stems, R. lasiostylus and R. Giraldianus. The last one is a strong, beautiful plant too, but it has rather insignificant black fruits, while the fruits of R. biflorus are of a wonderful amber colour or almost golden yellow, and of an excellent taste. Bailey is right in speaking of the variety as of a promising fruit-bearing as well as ornamental plant.

CAMILLO SCHNEIDER.

WEEDLESS PATHS AND COURTYARDS

SOME forms of tidiness in the garden savour of fussy artificiality which jars upon the nerves of those who love the apparent freedom of natural effects, but surely none will venture to suggest that weedy paths may be tolerated. Among all the labours of garden control no task is more irksome and extravagant in its absorption of time and effort than the constant weeding of hard gravel drives or the crevices between the slabs of paved garden walks. Weed-killers should, therefore, have a special interest at this season when time can ill be spared for unprofitable labour.

Nervous fear of handling poisons has prejudiced some minds against these labour-saving preparations, but be it remembered many things are commonly used without the slightest compunction, not because they are harmless, but because less emphasis has been laid upon the danger accompanying their use than in the case of weed-killers. Complaint against reiterated warning of the baneful power of weed-killers would be unwise; to be forewarned is better than to err in ignorance, and the one thing essential to safety in the use of poisons is to be clearly informed of the possible results of careless handling. The frequently recommended alternative to poisonous weed-killer is to use common salt, but that is a very poor substitute, for although immediate contact with weeds enables the salt quickly to discolour and maybe actually kill them, as soon as rains wash the salt into the gravel chemical conversion begins, and soon the salt becomes plant food, which encourages a more robust growth of weeds.

Arsenical weed-killer poisons the weeds, and leaves the poison in the surface gravel, and for a long period not only seeds fail to germinate, but stout weeds are prevented from thrusting new growths through the surface.

One of the most persistent weeds that may break through a firmly constructed gravel drive is the "bell-bind," or wild convolvulus. The depth to which the roots penetrate into subsoil of practically any description, not even excepting solid chalk, makes it impossible to kill an established colony at a single operation, but close observation of a particular pathway laid on a chalk hillside conclusively proved that after killing the developed herbage the poisoned surface arrested the progress of subsequent growths, killing them within an inch of the surface for a period of six months after a single dressing with weed-killer. The second season growth of bell-bind was much later in making its appearance, when a prompt application of weed-killer stopped its progress for the rest of that season. Last year—the third season—July was reached before the first few weak growths showed through the surface, and this year May has arrived with no necessity at present to use weed-killer on that path. The value of these results becomes apparent when one attempts to estimate the amount of tedious labour which would have been involved during three whole seasons and part of the fourth in hand pulling the growth of bell-bind, which has its roots deep down in a great seam of chalk. Even unskilled garden labour is costly to-day, and unskilled weeding frequently proves to be a vexatious waste of money, while the amateur who entirely maintains even a small garden in spare time will find plenty to do apart from incessant path weeding.

Powerful brands of weed-killer made by well known chemists are readily available, and small quantities may be purchased in sealed canisters or cartons, in liquid or powder form, from local horticultural sundriesmen. Their prices vary according to their strength, but when considerable quantities are to be used it is more economical to buy the brands which will stand greatest dilution, because it means less carriage charges, and even though the prices quoted may be inclusive of delivery, it is well to remember there is no such thing as "free" delivery, since railway companies do not carry goods without payment. Herein lies an advantage of weed-killers sent out in powder form, and large users will be well advised to bear this in mind, but for small gardens the liquid has the advantage of being more easily prepared for use without delay, no risk being involved by even a brief period of standing to dissolve as is necessary with powder.

Any of the following names on a vessel of weed-killer will be sufficient guarantee of good quality: Abol Limited, Joseph Bentley, Limited, Corry and Co., McDougall and Robertson, Cooper and Nephews, G. H. Richards, Ltd., Tomlinson and Hayward, Limited, Morris, Little and Son, Limited, Mark Smith, Limited, The Briton Ferry Chemical and Manure Company, Limited, Stonehouse Works Company, Limited, Robinson Brothers, Limited, G. Harrison, Acme Chemical Company, Limited, Garden Supplies, Limited. All brands are sent out with plain directions regarding the strength at which to use, and the method of mixing, and these should be accurately followed.

Galvanised water cans are better than painted ones, because the acids usually peel off the paint. A fine rose on the can is better than a coarse one, because too rapid a flow will cause the liquid to run off the hard surface of the path to the lower level of the sides, resulting in uneven distribution and waste of strength.

The main points to observe are to avoid using it when the ground is very wet or when rain threatens, and to take care that the weed-killer does not reach growing edging plants, grass verges, roots of climbers or drains which connect with ponds. Thoroughly wash all utensils *immediately* after use, and store weed-killer under lock and key. For the benefit of those who will not use poisonous weed-killers some non-poisonous brands are obtainable, and although these will only stand about half the dilution the poisonous brands will do, they are every bit as capable of destroying weeds.

L. I. ATRIS.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

SIMPLE GARDENING

AUTUMN CAULIFLOWERS AND WINTER GREENS.

NEITHER cauliflowers nor winter greens generally, withstand severe checks without suffering more or less. I know how difficult it is for amateurs always to devote the necessary time to early and intermediate transplanting which is such a help in the due preparation of the plants prior to their final planting-out. Usually, the seeds are sown in poor soil in an open border; the resultant seedlings are allowed to grow, often to a height of 1ft., before they are violently pulled up, generally in a dry state, when many valuable roots are sacrificed, and replanted in dry, poor soil, too, during the hottest days of summer. There need not be any wonder at the appearance of "club-bing," at delay in the formation of healthy roots and new. Frequently the plants are "clubbed" in their seed-beds before they are permanently put out. Do not sow seeds in the same bed year after year; do not even transplant the resultant plants in the same nursery beds, and do not finally plant them in the same quarters. Be content to grow fewer plants and treat them very well; the results will be much more satisfactory. Now, possibly many readers will possess beds of seedling plants of cauliflowers and winter greens. Some, no doubt, do follow the good plan of intermediate transplanting. I would persuade those who have not done so to try it this year. It is beneficial where ground is vacant, but doubly so where it is absolutely necessary to keep the young plants somewhere till ground is cleared. There is great gain, as the plants possess plenty of roots and good balls of soil, and are not seriously checked when finally transplanted if ordinary care be taken.

SUMMER WATERING AND PLANT FEEDING.

Watering, according to position of garden, its soil and the available water supply, may be a light or a heavy burdensome occupation. The feeding of plants is not, in any case, as a little of it goes a long way if correctly carried out. Suppose we consider the greenhouse and conservatory plants first. It is a fact that many residents in towns and their suburbs are obliged to pot their plants in unsuitable compost—at least, in such a mixture that does not induce free root-action. The consequence is that numerous plants are unsatisfactory, and the inexperienced cultivator at once applies large doses of strong manures. This is, of course, wrong; while roots are few and, for a reasonable time after plants are re-potted, clear water only should be used, and very carefully, too, as in a too dry or too wet soil roots do not increase satisfactorily. The right time to apply a stimulant to a pot plant is directly the pot begins to fill with roots—when the latter begin to form a network round the outside portion of the ball of soil. I am not dealing with any special kinds of manure, as space will not permit of it, but in every case follow the instructions given with the manures and be under rather than over in measuring out the quantities. Fruits are mostly benefited if stimulants are applied when they are swelling, before, and after, the stones in them harden. Vegetables, too, when the growth is beginning to be very active and pods are swelling or hearts forming. Flowering plants in borders when the flower stems begin to form. The soil should always be moist.

THINNING HARDY FRUITS.

The finest specimens of apples and pears are generally grown on cordon-trained trees. These trees are restricted

to one or two main stems, and they are, as a rule, carefully watched and attended to during the summer months, while the ordinary bush, pyramid or standard tree is not. All cultivators do not possess cordons, but they may grow really fine fruits on bushes, espaliers and standards if they will thin out in good time the smaller specimens. Plums, peaches and apricots on walls should have first place in this work, as they will be more forward. The thinning should be done gradually, not all at one time. The fruits to retain on wall trees are those that are prominent and placed well away from the wall. At the final thinning plums should be left at 7ins. apart, apricots 9ins. and nectarines 9ins., peaches being allowed a little extra space. These distances are for the whole tree. It may be that more fruits will form on certain branches than on others. In such cases leave the fruits closer together to make up for the bare branches, and so secure the full crop for the tree as a whole. Pears are easily thinned, but apples are more difficult, because they grow in close clusters. The one retained should not be loosened when the surplus fruits are removed. The letter *a* shows the fruit to retain; *b*, *b*, *b*, the ones to pull off; *c* shows the best apple of the bunch; and *d* the ones to remove. Timely and judicious thinning results in such specimen fruits as the one shown at *e*.

GATHERING AND PACKING FLOWERS.

It is a pleasurable occupation preparing ground and growing flowering plants in it, and much more so gathering and sending, by post or train, some of the resultant flowers to friends and hospitals. Soon, now, our gardens will be overflowing with hardy flowers and, if we desire to cut and pack some of them, we should carry out the work in the right way. Roses, no doubt, followed closely by sweet peas, will claim general attention. The first named do not retain their freshness very long, neither do the sweet peas. It is useless cutting roses half-developed or fully so. They should be in that stage just showing the colour in the buds. I once wished to make a shower bouquet for a competition, using a particular rose. Not having sufficient, I bought some more in the bud stage—this being permitted by the rules—and exhibited the bouquet three days later, all the flowers being half and three parts developed. It was awarded first prize. Sweet peas should have at least one flower-bud on each stem and not all the buds fully developed. Annuals and spikes of herbaceous flowers should be in a state about three parts developed. I think the ideal time to cut the flowers is very early in the morning. The plants should be watered the previous evening, the spikes cut early the following morning and forthwith placed in water in a cool shed out of draughts. Use damp moss (not cut grass, as the latter heats) round the stems. Pack the flowers gently but firmly together in wooden boxes. Cover the flowers first with white, then with blue tissue paper. Have the stems moist, the flowers dry. GEORGE GARNER.

Gardens Open to the Public.—Aldenham House Gardens.—The Hon. Vicary Gibbs has again kindly consented to open the gardens at Aldenham House to the public during the Saturday afternoons of July, August and September, and the August Bank Holiday, on the same conditions as previous years, viz., that no dogs be admitted, and that children must be under the control of grown-up persons. On Saturday, July 18th, the Elstree Floral Fête will be held, when admission will only be by payment at the gates.

The Gardeners' Royal Benevolent Institution.—The Right Hon. Austen Chamberlain, M.P., has promised to preside at the eightieth anniversary festival dinner of this Institution at the Grocers' Hall, on Thursday, July 2nd next.

National Gladiolus Society.—The committee of this Society has arranged for their show to be held at the R.H.S. Hall, Vincent Square, on August 25th. Schedules can be obtained from Mr. A. Amos, 10, Bergholt Road, Colchester.

GARDENING OF THE MONTH

FLOWER GARDEN.

ANNUALS.—Thin out. Transplant further batches. Sow a few hardy annuals for autumn flowering. Water frequently. Stake carefully any that have thin, straggling growths. Pinch the points of clarkia, calendulas, godetias and helichrysums.

BEDDING.—Plant out at once and water frequently until established.

BIENNIALS.—Sow in prepared beds wallflowers, myosotis, sweet williams, Canterbury bells, aquilegias, etc.

BULBS.—Lift soon, plant out in wild garden or dry off and later store in boxes.

CHRYSANTHEMUMS.—Stake border varieties, keep them free from pests.

DAHLIAS.—Plant out during the first week of June.

HERBACEOUS BORDERS.—Weed and hoe regularly. Water, if necessary. Restrict growths of strong-growing perennials, such as asters. Stake all plants soon, especially gladioli and hollyhocks. Fill in gaps with annuals.

LUPINS.—Sow seed of Lupinus arboreus, or strike from cuttings. Insert short-jointed shoots in sandy soil in a cold frame.

PERENNIALS.—Strike from cuttings and sow seed in pans in frames or in the open ground.

PESTS.—Fumigate the soil with carbon bisulphide for ants. Keep down aphis and caterpillars by spraying with Abol or Katakilla. Watch for slugs and destroy.

POLYANTHUS.—Sow seed of the Munstead strain. Lift and divide plants after flowering. Plant out in well prepared beds in partial shade. Water frequently.

ROSES.—Water rose garden. Feed roses with liquid manure. If attacked by mildew, dust with flowers of sulphur. Spray with soft soap and tobacco water for aphis. Pull up suckers of bush roses. Tie up ramblers and climbers.

SWEET PEAS.—Feed weekly with liquid manure. Water, if dry. Keep the surface hoed.

HARDY FRUIT.

APPLES.—Spray with soft soap, quassia extract to keep down aphis.

APRICOTS.—Stop gross shoots. Prune back side growths to within 6ins. Do not stop the leaders. Thin the fruit, and net the trees. Do not let them suffer from drought. Apply liquid manure at intervals.

CHERRIES, DESSERT.—Shorten back side growths, net the trees.

CURRANTS.—Summer prune the side shoots. Keep down aphis. Net the bushes if possible. Burn all prunings.

FIGS.—Regulate growths and tie in shoots.

GOOSEBERRIES.—Thin shoots of dessert varieties. Cut off and burn shoots infected with gooseberry mildew. Gather a portion of the fruit.

PEACHES.—Stop gross shoots. Lay in young wood. Thin partially the fruit. Syringe to keep clean.

PEARS.—Summer prune the young shoots. Do not touch the leaders. Thin cordon pears partially when fruit swelling and pinch side shoots gradually. Syringe regularly to keep trees clean.

PLUMS, WALL.—Shorten back side growths, lay in young wood. Water with liquid manure occasionally.

RASPBERRIES.—Mulch with rotted manure.

RHUBARB.—Cut off flower spikes and cease pulling at end of month.

STRAWBERRIES.—Hoe, lay clean straw under plants and net, if not already done. Water when fruit swelling.

VINES.—Disbud freely. Leave well placed strong shoots. Stop side shoots two joints beyond the bunch.

VEGETABLES.

ASPARAGUS.—Do not cut after mid-June. Give a dressing of salt.

BEANS.—Stake runner beans. Make another sowing of dwarf and runner beans. Pinch tops of broad beans if aphis present.

CARDOONS AND CELERIAC.—Plant out now.

CAULIFLOWERS.—Plant out. Water those in permanent quarters.

CELERY.—Plant out now. Water for a week or two. Dust with soot.

CHICORY.—Sow early in the month.

CUCUMBERS.—Plant out another batch in frames. Keep frames closed for several days. Damp down and syringe regularly. Peg down and stop established cucumbers.

ENDIVE AND CORN SALAD.—Sow now for early supplies .

JERUSALEM ARTICHOKES.—Draw up soil round tubers.

LEEKS.—Hoe between the rows and plant out remainder.

MARROWS.—Plant out now and protect with hand lights until established.

ONIONS.—Dust with lime and sulphur or spray with Burgundy mixture, if attacked by mildew. Give a light dressing of nitrate of soda. Sow onion "sets" on poor soil. Spray with paraffin emulsion to ward off onion fly.

PEAS.—Sow Autocrat peas during the first week. Draw up soil round plants, give a light mulch of rotted manure, if possible.

POTATOES.—Earth up and leave a groove on top of the ridge. Spray with Bordeaux mixture as a preventive against potato blight.

SEAKALE.—Disbud, leaving one strong shoot only.

SEEDLINGS.—Plant out in showery weather, cabbages, early broccoli, leeks, kales, savoys, Brussel sprouts and tomatoes.

SPINACH.—Thin seedlings, and hoe. Sow at once New Zealand varieties.

SPINACH BEET.—Sow now.

TURNIPS.—Sow on shady border. Thin out seedlings. Dust with soot and lime to check turnip fly.

GENERAL.—Hoe regularly. Keep down all weeds. Thin beet, carrots, parsnips.

SHRUBS.

FLOWERING SHRUBS.—Prune, after flowering. Lightly fork through the shrubbery.

RHODODENDRONS.—Remove seed heads.

BOX EDGING.—Clip now.

SUCKERS.—Remove all from grafted trees, such as lilacs, Viburnum Carlesii, etc.

ROCK GARDEN.

AQUILEGIA GLANDULOSA.—Sow seeds in cold frames. Transfer to flowering quarters when quite young. Water regularly.

AUBRIETIA.—Sow seed in frames, in pots or pans, with ample drainage. Shade pans until germination takes place.

GENERAL.—Hoe, weed and keep surface loosened. Water liberally. Cut back rampant rock plants to prevent them over-running others. Propagate by cuttings such plants as aubrietia, arabis, alyssum, iberis, etc.

FLOWERS UNDER GLASS.

BOUVARDIAS.—Pot up young plants. Stop them at each second leaf. Syringe to keep down pests. Vaporise with sulphur to keep down mite. Shade if very hot.

CALANTHES.—Feed with liquid cow manure. Give a fair amount of heat. Shade slightly and give liberal supplies of water.

CALCEOLARIAS.—Sow seed of herbaceous varieties. Shade and cover with glass until after germination. Prick off into pans of light, rich soil, when large enough. Place in a frame in a cool position.

CARNATIONS.—Select healthy malmaison carnations for layering. Plant in cold frames and later layer in usual way. Lift and pot when rooted and store in a cold frame or greenhouse. Pinch points of tree carnations. Syringe daily. Stand outside in frames carnations which have finished flowering. Syringe to keep down red spider.

CINERARIAS.—Prick off into boxes and place in a frame in a shady situation.

CHRYSANTHEMUMS.—Water those standing outside. Stake and tie the plants. Give final potting at once if not already done. Leave room for top-dressing. Watch for leaf miner. Remove infested leaves and syringe with quassia extract. Stop late flowering bush varieties.

CYCLAMEN.—Place in a cold frame, shade and syringe. Sow seed in slight heat.

HUMEA ELEGANS.—Sow seed now in pans. Place in slight heat.

LILIUMS.—Stake and tie loosely. Feed.

MIGNONETTE.—Sow in a cold frame.

POINSETTIA.—Take cuttings with a heel. Select young shoots about 4ins. in length. Insert singly in pots and place in a warm propagating case. Shade and do not let the cuttings flag.

PRIMULAS.—Sow seed of P. kewensis, P. verticillata and P. floribunda in cold pit or greenhouse. Prick off and keep in frames for the summer.

ROSES.—Top-dress and stand outside on boards in full sun. Spray with potassium sulphide if mildew seen. If attacked by aphis, spray with quassia extract and soft soap or Abol.

STOCKS.—Sow, in a cold frame, Brompton stocks for winter flowering. Remove lights when germination has taken place.

GENERAL.—Prune flowering shrubs. Ventilate well, water twice daily and damp down the walks. Stand any suitable hard-wooded plants outside on boards or on an ash bed.

FRUITS AND VEGETABLES UNDER GLASS.

APRICOTS.—Pinch points of side growths. Syringe under leaves to keep down red spider.

FIGS.—Do not let these suffer from lack of water. Ventilate freely trees ripening fruit.

MELONS.—Top-dress mounds with rich compost. Maintain a warm atmosphere. Keep thrips and red spider in check. Admit air more freely when fruit ripening. Support fruit in nets.

ORCHARD HOUSE.—Give copious supplies of water to pot fruit. Feed with liquid manure when fruit set and give a dressing of some reliable fertiliser. Remove superfluous shoots and pinch side shoots to six or eight leaves, but do not touch the leader. Ventilate well and leave on a small amount of ventilation each night. Vaporise house directly aphis seen.

PEACHES AND NECTARINES.—Give more air. Give a good watering just as the fruit begins to show colour. Do not syringe when fruit begins to ripen, but continue to damp down occasionally to prevent an attack of red spider. Thin fruit and tie in young shoots.

VINES.—Water well before colouring. Prevent scorching. Thin late varieties. Do not thin the shoulder too much. Support upper arms with raffia. Pinch and regulate the shoots. Give plenty of air whenever possible.

CUCUMBERS.—Top-dress, feed with liquid manure. Clean out any exhausted plants, wash down house, remake mounds of soil. Plant out young cucumbers when soil warmed through. Damp down and syringe twice daily.

TOMATOES.—Top-dress, feed frequently with liquid manure. Pinch side growths. Tie up regularly. Ventilate night and day. Give a dusting of Clay's fertiliser at intervals. Fumigate with hydro-cyanic acid gas if white fly seen.

TULIP NOTES

Early Tulip De Wet.—This is an orange—or, perhaps, to be more accurate, a reddish-orange—sport from that fine tulip, Prince of Austria. My first introduction to it was in Amsterdam some years before the war, where it helped to decorate one of the specimen rooms at a large exhibition of women's work. Ever since then I have kept my eye upon it, and for a long time I have had it in my own garden. Familiarity has bred increasing appreciation, and I can now say that anyone who wishes to have one of the most beautiful, one of the sweetest and one of the most friendly of *all* early tulips in their garden must not forget to order De Wet. The flower is long shaped, and the orange ground of the petals is veined with red, which is more pronounced round the edges than in the centres.

Six days before writing these lines, a visitor pronounced it to be a sport of Prince of Austria by its scent. As to height, it is quite as tall as its sire. Advantage may be taken of this, if an early tulip bed is wanted, to introduce some Cardinal Rampollo, which, while being considerably dwarfer, has much the same colouring. To me a variation in height is more pleasing than a rigid uniformity.

Early Tulip Standard Silver.—Before the dawn of the twentieth century more striped varieties of tulips were to be found in our bulb lists than there were in 1924. I made it my business last year to try to get together a few of these old stagers. I wanted to show visitors to my garden what the "mania" tulips were like. They were all what we now call earlies; and what differentiates them from those with which we are now so familiar (*e.g.*, Yellow Prince, Prince of Austria and Cottage Maid), is that they were all striped. That these were the sort of thing that Petrus Hondius saw grown to excess (as he thought) in his neighbour's gardens there is no doubt. The first half of the seventeenth century was prolific in the production of both coloured and black and white flower pictures. In all of them there is the tell-tale leaf high up on the stem, which tells us they were earlies. Standard Royal Silver, or Standard Silver, or Silver Standard—for it has all these *aluses*—is undoubtedly one of the most beautiful of these striped early flowerers. The way the white and scarlet are combined, and its shapely pointed petals, give a peculiarly smart, well groomed appearance to the blooms. It has its counterpart in scarlet and gold, which is known as Standard Gold, but it is not so effective.

Other ancients are Arms of Leiden, Roi Pepin, Admiral Reinier, Globe de Rigaut and, of the edged type, Lac Bachuijen and Lac van Rijn. This edged type seems to have existed since the beginning of tulips in western Europe. It is distinguished by having some shade of mulberry red blooms with a distinct ivory white or cream edge to the petals. It seems to have been ignored in the eventful mania years 1635-37.

Mendel Tulips.—In a note in THE GARDEN a few weeks ago I promised to give my experience with these newcomers in the open ground. One year's trial under glass commended them as a distinct acquisition. It is the same with those outside. There are most beautiful shades among them, which are quite different from the colourings found among the earlies. I have one called April Queen, which is reminiscent of the pink cottage variety Sir Harry; and another, Early Beauty, a long flower of the softest rose with a little more than a suspicion of orange along the edges of the petals. Oranja and Salmoran are different shades of orange, and so on.

This is, as it were, the second lap. I must now wait and see what sort of an increase there will be when the bulbs are lifted. It makes the whole difference. No, or very poor, increase is more than a wet blanket on a bulb's prospects; it is a veritable extinguisher. Where are all those exquisite varieties that poor Walter Ware staged at the big Tulip Conference in London in May, 1915, and for which he was awarded a certificate of appreciation? Lady Love, perhaps the most charming of them all, practically makes no offsets. I bought a little stock of a very great beauty after the style of Eleanora many years ago, but I have now only a few more than when it first came to Whitewell. A tulip that emulates Peter Pan will find it does not share that person's popularity.

Tulipa persica (a small yellow species).—Try this cheap variety as a pot plant in a cold or very cool house. I never thought of such a thing, but twice this year in places wide apart I have seen it done with very satisfactory results. JOSEPH JACOB.

CORRESPONDENCE

WHERE WILL IT END?

SIR,—Why not take a leaf out of the Stud Book and follow in the footsteps of the pedigree stock-breeders? Why name immediately every new hybrid that is born? The first daughter of Mumtaz Mahal will be known for a year or two as Mumtaz Mahal filly, and will not have a name in her own right until registration papers have been taken out for her. A colt or filly may win races long before baptism. A horticultural stud book would be a universal work of reference. The quotation of the stud book number would be sufficient to identify and describe a plant. The *imprimatur* of the stud book would be prized by the hybridist and authoritative to all.—E. E. T.

BLACK CURRANTS.

SIR,—It is a pity that more people do not know as much about the Baldwin as does Mr. Copley, as evidenced by his letter on page 252 of THE GARDEN; but I should like to elaborate rather than contradict some of his remarks.

Baldwin is, as he states, generally the first of the black currants to bloom, but it actually suffers less from frost both at this time and later, than any other sort I know, so that if late frosts mar the prospects of a crop from the Baldwin, other varieties are still more badly damaged.

In my own opinion, cold winds are the worst enemy of the Baldwin and, indeed, of most black currants at blossoming time; but the shelter of a hedge or a few judiciously placed wattle hurdles is not difficult to provide in a garden and will often be found to work wonders in a bad year.

The blossoms of the Baldwin are so formed that pollination is exceptionally easy, a fact that, I believe, has a good deal to do with its astonishing cropping powers, a great deal of fertilisation being carried out by wind that would need the help of an insect in other varieties.

I think Mr. Copley rather defames the Baldwin *à propos* of its colour, other things being equal. I cannot recollect having had lower market returns for Baldwin than for other sorts; indeed, it is usually the other way about, owing to the better condition in which it arrives in the market.

I hope that Mr. Copley's opinion that Baldwin will never become really popular is incorrect; the insatiable demand of the jam-maker for Baldwin leads me to think that it is so.—A. H.

CAMPANULA LANATA.

SIR,—Some months ago, describing wild flowers in a Greek island, I wrote of this campanula as being of a "luminous campanula blue." I see Colonel Enever Todd sets beside this another description of the colour as "white, yellow or purplish." I think the campanula I found really was lanata. I saw it growing at Kew when I returned from Greece. But at Kew the flowers were of a yellowish or whitish colour, like the buds or half-opened flowers as I found them. I mention this in case someone who grows the plant may like to try imitating the conditions of its native habitat. Where I found it the plant grew only in complete shade, in cracks and ledges of vertical limestone cliff. Against the rosy grey of the rock the big Canterbury bell flowers shone with a surprising brilliance.—A PAINTER.

ROSA HEMISPHÆRICA.

SIR,—In a recent article in THE GARDEN the introduction of the old double yellow rose (Rosa hemisphærica) was ascribed to "Celsius," a typographical error for Clusius that one may hope was obvious. For the story, which Clusius tells in the "Rariorum Plantarum Historia," of his first acquaintance with the rose in a toy garden of cut paper that he saw at Vienna, is well known. But since writing of this rose I find that Joret in "La Rose dans l'Antiquitée et au Moyen Age," states that Claude Mollet, in his "Théâtre des Plans et Jardinages," 1563, refers to R. hemisphærica a few years before Clusius published his description of it. I have not had an opportunity of verifying the reference. It is a pity that this fine old rose is rather too tender for most parts of this country, but it is still in cultivation here and I believe that there is an old specimen in a garden near Woking, while at least one of our rose growers lists it in his catalogue.—F. A. H., *Chesham Bois.*

VIBURNUM BITCHUENENSE.

SIR,—One of your correspondents stated just lately that Viburnum bitchuenense was much superior to V. Carlesii, the flowers being larger, and pinker before opening. Messrs. Hillier and Sons of Winchester quote V. bitchuenense, and here is their reply to my enquiry: "The above plant (V. bitchuenense) is a poor thing, flowers very thin and not showy, and we would think it advisable for you to procure a better variety." Does your correspondent think that either he, or Messrs. Hillier and Sons, have got an incorrectly named variety, or can he have compared the V. bitchuenense with the inferior variety of V. Carlesii—for I have been told that there are two varieties of this latter plant in commerce, one much inferior to the other as regards size and waxiness of the flowers. I should be glad to know where he procured the V. bitchuenense, and if he can throw any light on the matter. V. Carlesii is such an exquisite thing that anything superior would be a tremendous acquisition.—A. L. B.

A BOTANICAL DICTIONARY.

SIR,—Mr. C. F. Gray's suggestion of a dictionary of botanical Latin is a valuable one. As a newcomer among gardeners, I find it very difficult to remember distinguishing Latin terms, because as a general rule I have not the foggiest idea what they mean. So many plants are "paniculata," "rupestris," "pulchellum," "latifolia," "canescens," but not knowing what these terms mean they convey nothing to me. In other words, a great many of us know and use these names purely parrot-fashion and not intelligently. — GWENDOLYN ANLEY, *Woking*.

SIR,—As a regular subscriber to THE GARDEN, may I say how very useful such a botanical dictionary as C. F. Gray, Bourneville, proposes would be to many. In my opinion there should be no illustrations, nothing which would prevent its being bought by any employee, and it should have a clear "Introductory Explanation." Would it be possible to get the Fellows of the Royal Horticultural Society to guarantee a sufficient sum to bring out a book which would be of universal use. I would like to underline the words of the writer, "It should be quite a small pocket volume, also quite small in price."—EDITH W. HUTH, *Wokingham*.

SIR,—I was very interested in reading C. F. Gray's letter dealing with the pronunciation of botanical names. Even such everyday names as cyclamen and schizanthus are seldom pronounced alike. The reason, of course, is very obvious. A boy, when he commences work in a garden, naturally picks up the pronunciation of plant names from the head or under gardeners, and invariably continues to use the pronunciation given to the plants, whether right or wrong. As time goes on he hears plant names pronounced differently and is at a loss to know which is proper. Apart from the confusion this causes, a lot of interest in plants is lost, because, how can a man interest himself in a plant the name of which he is afraid to pronounce? Nothing annoys me more than to come across a plant name I cannot pronounce, which I am sorry to say often does occur. One looks in vain for a pronouncing dictionary of plant names at a price a working gardener can afford to pay. The cultural side of the plant gives the gardener plenty to think about, as climate, soils, etc., play a large part in success or failure, but pronunciation would be the same in all parts, if a Standard Pronouncing Dictionary could be brought out.—F. C. KING, *Milnthorpe*.

ERYTHRINA CRISTA-GALLI.

SIR,—*Re* Mr. Coutt's remarks on the coral plant, Erythrina Crista-galli, as a suitable plant for the greenhouse, it may be interesting to say that it is practically hardy in Devon and Cornwall if but a covering of cinder-ash or similar material be placed over the rootstock from November to early April. This plant stood out for near half a century to my knowledge at Bicton under a south wall, flowering profusely each year, proving a most interesting plant to all visitors.—J. MAYNE.

ON MANURES.

SIR,—A very interesting article in THE GARDEN recently discussed the preparation of mixed manures for horticulturists, and favourably mentioned many of the better articles on the market. That discussion was extremely valuable in so far as it gave the opinions of the users of mixed manures. The writer hopes that a few words of "inside information" will not only supplement the general knowledge of the subject of manuring but will also bind consumers and producers in closer ties of friendship and of mutual trust. The writer, with several years of scientific and practical experience of this subject, would strongly emphasise the fact that one cannot know too much about the type of soil, crops, previous manurial treatment and even climatic conditions in helping an enquirer to obtain the finest possible results. The writer has often given advice on the actual mixing of manures and submitted actual samples. Now, in manuring, the baser or less soluble manures are essential in opening up heavy soils and giving body to light soils, but no one ought to have to pay for base manures which are not available to crops as manures. In other words, only the most finely ground base manures are worth much, and these, in many cases, are extremely valuable. Quick-acting manures are very necessary, but one can imagine the crops rendering small thanks for splendid dinners for a week or two and starvation after a few days of rain. Thus the man who knows his job makes a carefully calculated mixture of both classes of manures, and practical experience invariably supports him. In agriculture the noble progress of the last decade was largely the outcome of the long period and investments of our forefathers in slow-acting manures. To avoid waste of money to the less enquiring men certain principles must be known. Acid soils need lime and alkaline manures where possible. This involves reducing superphosphates or dissolved bones, sulphate of ammonia and natural manures, or substituting bones, basic slag, nitrate of soda, etc. Alkaline soils are rare, but they can stand the above acid manures. We repeatedly find a deficiency of lime in soils submitted, although excess lime is too hungry for manures to be profitable. As to general principles of manuring crops, it may be that, briefly stated, leafy crops desire nitrogen, seeds desire phosphates and starchy crops (bulbs, roots, etc.) potash. But *all* plants require some of each. Individual crops have marked peculiarities, with the result that the subject is full of pitfalls for the amateur. Manufacturers produce standard mixtures for flowers, fruit, market gardening, and special ones for tomatoes, potatoes, vines, roses, chrysanthemums, lawns, etc., and these, from reliable firms, are excellent and economical.—GEO. WALWORTH, *West Bromwich*.

SUNDRIES AT CHELSEA SHOW

(*Continued from page* 320.)

Messrs. G. Hayward and Co. were exhibiting greenhouses, portable hand-lights and heating apparatus.

The Paramount Furnishing Company had very comfortable garden chairs and also tables to match. These were made of sea grass, which does not creak, has a certain amount of give in it, and is very durable.

A small group of inexpensive garden furniture was exhibited by Messrs. T. Syer and Co.

The words "Say it with flowers" bedecked the stand of the Florists' Telegraph Delivery Association, which has a membership of 3,000 florists in all parts of the world. This Association undertakes to deliver fresh flowers to almost any place at home or abroad, however distant it may be.

The Padworth Industries had some solid and well made garden chairs and seats.

Really good fibrous turf loam is often hard to get, but Mr. A. B. Johnston had samples of good quality loam on his stand.

A general exhibit of sundries was shown by Messrs. R. Melhuish, Limited. Fruit protectors, lawn mowers, tools, syringes and plant foods of all kinds were for sale.

Mr. J. Haws was exhibiting a selection of his famous watering cans.

The Godiva Engineering Company were demonstrating the working of their motor mower and grass edge cutter.

Messrs. George Monro, Limited, the Covent Garden salesmen, had a varied exhibit of sundries. Baskets, china bowls, tools and fertilisers were shown.

The gardening gloves shown and made by Miss A. Everitt should, by their appearance, be very durable.

Messrs. George Fowler Lee and Co., Ltd., were showing fruit and vegetable preserving appliances.

The South Metropolitan Gas Company had an exhibit of sulphate of ammonia, a wood preservative and disinfectants.

The Radium Fertiliser Company were exhibiting their patent fertiliser, with which many people have had good results.

Mr. C. A. Jardine was demonstrating the cutting powers of the super-secateur which he has invented.

Good quality is the keynote of every implement manufactured by the Wilkinson Sword Company. A large selection of grape scissors, pruning and budding knives, flower scissors and secateurs were on view at this stand.

A gay and artistic effect was produced by the exhibit of coloured bowls and chairs shown by the London Gardens.

Bird-baths, sundials and garden ornaments in various shapes and designs and made of artificial stone were shown by Messrs. Kelly and Co., Limited.

Messrs. H. Scott and Sons exhibited fertilisers, fruit tree washes, plant stakes, barrows and samples of peat and loam.

All the equipment necessary for successful bee-keeping was exhibited by Messrs. E. H. Taylor, Limited, the bee specialists. A multi-tray cabinet for storing fruit was also shown on this stand.

The New Cross Timber Company had an exhibit of rustic garden furniture, arches, fences, etc.

Messrs. A. Smellie and Co. had several useful and improved implements among their large assortment of sundries.

In a case on the exhibit of Messrs. C. T. Overton and Sons bees were busily working. Hives, combs and all the necessary oddments for bee-keeping were being shown.

Mr. Walter Unwin exhibited garden furniture of rustic design, also loam and leaf-soil.

Mr. William Sinton was showing polished oak plant tubs and vases which were well made. "Citadel" chairs were also shown.

A selection of folding tables was shown by Messrs. Abbott Brothers. These tables are very light, but yet strong.

A collection of hand-made baskets and leather goods was shown by the "Not Forgotten Association." All the goods on this stand were made by disabled soldiers who are still in hospital, many of them being permanently disabled.

Messrs. T. H. Webster and Son were showing to the public labels and the "Cascade" nozzle.

Trucks, ladders of all lengths and wheelbarrows were shown by Mr. H. C. Slingsby.

Lord Roberts' Memorial Workshops had an exhibit of garden furniture, baskets, etc.

Messrs. Holtzapffel and Co., Limited, exhibited garden tools of high quality which were hand forged from the best steel.

Mrs. Torkington was showing garden labels and indelible ink with which to inscribe them.

Messrs. Castle's Shipbreaking Company, Limited, had a good exhibit of garden furniture.

In our report of Mr. Reginald Winder's formal garden at Chelsea Show, an unfortunate printer's error occurred relating to the paragraph dealing with berberis and double-flowered gorse. This paragraph did not refer to Mr. Winder's garden.

GARDENERS: III—WOMEN

FOR centuries the British Isles has been famous, not only for its gardens, but also for the gardeners it produces. Thus has been evolved a craft that has an immense tradition behind, with its consequent feeling of *esprit de corps*. All famous gardens have been man made, and it is only within the past few years that women have seriously taken up gardening. Quite apart from the manual work attached to horticulture, many of the great qualities of our gardeners in the past have been attained because they have been trained in big gardens, where they have been through the mill in every kind of gardening. Their entire training has been practical. It is true that those who have learned something of the theoretical side of the subject have probably risen higher than the man with no theoretical background, but anything of the theory of gardening that they may possess has been learnt on their own initiative.

The woman who wishes to take up gardening for a living starts with this great handicap, that she has never been through the mill in a great private garden. For obvious reasons it is difficult for a woman to obtain the necessary early training in a private situation, so she has had to fall back either on a nursery or on a horticultural college. In a nursery she will probably learn only one branch of horticulture, and however skilled she may be in this branch, she will lack a general horticultural education. In a horticultural college there is too much theory and too little practice. Far be it from me to belittle the excellent training given by these colleges, but their very nature makes it difficult for them to complete what they have started. Most of them take in pupils who to begin with do not know a cabbage from a watercress. Owing to the numbers of students a great deal of the teaching has to be by rule of thumb, and individual effort counts for little. A course may take one or two or three years, and so a definite period has to be set aside in which to learn propagation, and another planting, and so on. In fact, it is teaching gardening by time-table: gardening, a trade where time counts for nothing and the longer a man lives the more he finds he has to learn.

This applies both to male and female students, but the female is the more handicapped, for a male can always begin or finish his training in a garden, which a woman cannot always do. The consequence of this rush of learning is that women know either too much or too little of gardening. Theoretically they often know more than a man-gardener; in practice it is the opposite. This handicap is a great pity, for in some garden work they are far superior to men. Wherever neatness of handiwork is required, such as in pricking off seedlings, they are pre-eminently superior. They are usually more tidy than a man and they have more imagination and so are frequently better designers of a garden or arrangers of colour schemes. But these assets do not make a thorough gardener and so their present utility in a garden is limited. The great blessing of gardening as a profession is its never ending variety, but if you are limited to one particular job, because you are expert at it alone, this makes even the pleasantest occupation become purely mechanical in time.

Unless some scheme can be devised by which a woman can get a general groundwork for at least a year *before* entering college, I see no great future for women as professional gardeners.

Apart from the professional side, there are thousands of women who have taken up gardening as a hobby. Many of them have become extremely proficient gardeners, but the majority of them are only interested in the result. They leave the why and the wherefore of a plant's growth to a male relation or to their gardener and so are extremely ignorant about the fundamentals of gardening. They can talk glibly about the beauty of this or that, but if you ask them if it is propagated by division or cuttings or layers, they either make a guess or look at you in blank amazement. But even they possess certain qualities in which they excel. They frequently have that undefinable factor, an "eye" for a plant. Their judgment is frequently superior to that of a man, if they can keep their keenness in check; they almost always have a better idea of colour and of the general planning of a garden.

Although it is difficult to find a man and a woman who can run a garden in perfect harmony, yet there is little doubt that intelligent team work makes the best gardens. Each possesses something which the other lacks, and so, theoretically, co-operation should achieve the best results. E. H. M. C.

RHODODENDRON RACEMOSUM & ITS ALLIES

BY H. F. TAGG.

IN THIS ARTICLE THE CHIEF CHARACTERISTICS OF A FEW MEMBERS IN A CLOSE CYCLE OF RELATIONSHIP ARE CLEARLY DESCRIBED, AND IT SHOULD PROVE OF ASSISTANCE TO THOSE WHO ARE IN DIFFICULTIES OVER POINTS OF NOMENCLATURE.

THE explorations of Mr. George Forrest and Mr. Kingdon Ward have added to cultivation three species of Rhododendron which, like R. racemosum, bear freely, in April, fasicles of small rose-coloured or white and pink-tinted flowers.

The three species are: R. mollicomum, Balf. f. et. W. W. Sm.; R. pubescens, Balf. f. et Forrest; and R. hemitrichotum, Balf. f. et Forrest.

R. racemosum has been in cultivation for some thirty years and as it is easily propagated, it is now fairly common in gardens. Discovered by Delavay in 1882, it was first raised from seed in Paris in 1889. In 1892 it was introduced to cultivation in Britain by Messrs. Veitch. Forrest gathered it in 1904 in Yunnan and it was thus one of the earlier re-introductions of Yunnan Rhododendrons made by that explorer. It was also collected in western Szechuan, where it is rare, by Wilson, in 1908. Since 1904 numerous gatherings have been made by Forrest and Ward in Yunnan, some of which appear to be better garden plants than that originally introduced.

R. mollicomum was found by Forrest in 1913-14 on the mountain slopes of the Chungtien Plateau and north-east of the Yangtze Bend. There are specimens in the Herbarium of the Edinburgh Royal Botanic Garden of plants which flowered at Caerhays Castle in 1922, raised from Forrest's seed under the type number Forrest 10347. This is the earliest record I have of its flowering in this country, but it is very probable that Forrest's No. 10347 flowered in cultivation at an earlier date.

In 1921 Mr. Kingdon Ward gathered three specimens, to which he gave the numbers 3952, 3952A, 3953. The herbarium specimens are respectively R. racemosum, R. mollicomum, and R. pubescens. These were gathered east of the Yangtze Bend and the serial sequence of the numbers suggests that the plants were growing close together. From seed sown under the number 3952 there have been raised both R. mollicomum and R. pubescens, and from 3952A, R. pubescens.

R. pubescens flowered last year at Headfort Gardens, Kells, Co. Meath; this year at Tower Court, Ascot, at Edinburgh, and at Caerhays Castle, Cornwall, under the number Ward 3952. The species was first found by Forrest in 1918 on the slopes of the Muli Mountains (Forrest, No. 16812).

R. hemitrichotum was found by Forrest in 1918 (Forrest, No. 16250), on the slopes of the Muli Mountains, and in 1921 Ward gathered it under the numbers 4050 and 4994. I have no record of it having flowered in cultivation until this year, when, under the Forrest type number, it flowered at Caerhays Castle, and under the Ward numbers quoted, it flowered at Tower Court and at Edinburgh. It should be noted that not all the plants growing under the quoted Ward numbers are typical R. hemitrichotum. Some appear to be forms of R. racemosum.

Features common to the four species are: Shrubs freely branched, twiggy and of scrub habit, with small leaves, pubescent, hairy or waxy below. Flowering buds, each bearing fasicles of two to four flowers, borne in the axils of foliage leaves on the upper parts of the shoots. Flowers small, with short tube (long in R. mollicomum), lobes five, lepidote outside and hairy within at the throat of the tube. Stamens ten, puberulous to hairy at base. Peltate scales present on stem, leaf (upper and under surfaces), pedicel, calyx, corolla and ovary.

Characters which distinguish typical plants of the species are:

(*a*) Species with leaves grey-white below.

1.—R. racemosum.—Leaves elliptic, oval or obovate, about 1½ins. long, ¾in. broad. Leaf upper surface not puberulous in typical forms. Calyx lobes not ciliate. Ovary lepidote, not puberulous.

2.—R. hemitrichotum.—Leaves narrowly oblong or lanceolate, about ¾in. long, ¼in. broad. Leaf upper surface densely and persistently puberulous with short, soft white hairs. Calyx lobes ciliate. Ovary lepidote and puberulous all over.

(*b*) Species with leaves pale green below, puberulous or bristly.

3.—R. mollicomum.—Leaves narrowly oblong or oblong-obovate, about 1in. long, ¼in. broad, puberulous above and below, not bristly. Calyx crateriform, lepidote and puberulous, not ciliate. Corolla oblique, tube slightly curved, longer than the lobes. Style puberulous at the base for about one third of its length.

4.—R. pubescens.—Leaves narrowly oblong-lanceolate, about 1in. long, ¼in. broad, pilose and bristly above and below. Calyx setulose-ciliate at the margin. Corolla-tube not longer than the lobes. Style glabrous.

In R. racemosum and R. hemitrichotum the leaf under surface is covered with minute wax-covered pegs. These give to the under surface the grey-white colour. In both species hairs are absent from the under surface, but peltate scales are present, sunk in small pits in the epidermis. In R. hemitrichotum the young stem, pedicel and the upper surface of the leaf is clothed with short soft white hairs. These are absent in typical R. racemosum, but there are forms that are more or less puberulous on stem and leaf upper surface. The leaf shape and size are distinctive in typical forms, but in cultivation there are forms intermediate between R. racemosum and R. hemitrichotum. They may be hybrids. Typically the ovary of R. racemosum is covered with scales, but hairs are absent. In the forms with puberulous foliage, hairs may be present on the upper part of the lepidote ovary.

R. mollicomum has a soft, puberulous hairiness on the leaf upper surface and on the under surface also. A wax covering is absent and from R. hemitrichotum it is distinguished also by the absence from the latter of hairs on the underside of the leaf. R. mollicomum is distinct from the other three species in its bilateral corolla, with relatively long tube. In the other species the corolla tube is wide and short and the flowers are almost regular. Moreover, the style, glabrous in R. hemitrichotum and R. pubescens, is conspicuously hairy at the base in R. mollicomum.

The leaves of R. pubescens are clothed above and below with soft, short hairs, and with longer bristle-like hairs also. The presence of the latter on foliage and stems distinguishes this species from the other three. From R. mollicomum, its nearest ally, it is distinguished also by its glabrous style and ciliate calyx. On the type plants the leaves are about 1in. long, lanceolate or oblanceolate, but young plants in cultivation show variation in the size and shape of the foliage, generally speaking the leaves are larger and may be as much as 1¾ins. long. The flower colour and to some extent the flower shape of this species, convey a suggestion of "apple blossom" on a small scale.

All are essentially scrub plants from open areas, although odd gatherings of each have been made in thicket or open forest. As they come from the same areas as R. racemosum it is probable that cultural treatment that suits R. racemosum will suit the others also, and it will most likely be found that, as with R. racemosum, the best effects in gardens will be got when plants are grown in clumps or masses. Indeed, there are few species of the genus, of shrub or bush habit, that do not lend themselves to this treatment with happy results.

The species here described should make excellent rock garden plants grouped on sites suitable for small shrubs. I think, also, that they will be found suitable for banks and slopes where other forms of the genus fail for want of soil moisture. This is a speculation only. We know too little about them in cultivation to be able to indicate with any certainty the conditions that will suit them best, but it can be said with certainty that they are all xerophytes. They have those morphological features which we generally associate

Digitized by Google

with conditions of physical or physiological drought. The narrow leaves with thick cuticle and hairy, scaley and waxy covering, and the tendency of the leaf margin to curl over and protect the lower transpiration surface, are adaptations which impede loss of water from the leaf surfaces. Such adaptations are characteristic of plants growing in dry situations, and where atmospheric factors tend to dry the plants quickly. They are also found in plants growing in situations where soil factors render the quick uptake of water by the roots difficult, although the soil may not be physically dry. These conditions are met with on unretentive soils—sandy, gravelly or stony—and on peaty moors, where, in spite of a physical wetness, absorption of water by the plant is difficult owing to the presence of humus acids. The wet peat, to the plant, is physiologically dry.

In this connection it is interesting to note what collectors say about the situations in which their various gatherings of specimens were made.

For R. hemitrichotum we are given by Forrest such situations as "open rocky pasture," "dry open meadows and rocky slopes," "dry rocky slopes amongst scrub," "open thickets." Ward says of his 4050, "In dry oak forest on steep slopes, much better and flowers more freely as a small shrub (1ft. to 2ft.) on open sheltered slopes in the scrub belt."

R. mollicomum has been gathered "in open scrub," "in open situations among scrub," "on margins of pine forest," "in open thickets in dry situations," "on dry slopes."

R. pubescens was gathered by Forrest "in thickets amongst scrub," and "amongst scrub on dry rocky slopes."

R. racemosum in its many forms has been gathered in more diverse situations. We have it from areas with field notes, such as "open scrub," "open dry stony situations," "open situations on downs," "open mountain pastures," etc. As with the other three species it has been gathered in the more open forest formations, such as "mixed open oak and pine forests" and "open situations on the margins of pine forest." R. racemosum is recorded also from "open boggy situations" and "peaty boggy ground in open situations." As already explained, peaty bogs are physiologically dry. This occurrence of R. racemosum on such physically diverse soils as "dry stony situations" and "peaty bogs," has a parallel in the distribution of some of our native heaths. Some species of Erica and Calluna vulgaris are essentially moorland and peat-soil denizens in the north and west, but in the south and south-east the same species occur on dry, gravelly or sandy "heaths" and in dry patches in open mixed woodland.

Other Rhododendrons related to the four here discussed are: R. spiciferum, R. scabrifolium, R. virgatum and R. oleifolium.

R. spiciferum is a near relative of R. pubescens and may be regarded as the southern representative of the latter species. It comes from the district of Yunnan-fu. R. spiciferum is a more asperous plant than R. pubescens. In many features it is an intermediate species between the narrow leaved, bristly, but not asperous R. pubescens, and the much broader-leaved plant, R. scabrifolium, with its marked foliar asperities.

R. virgatum comes from Sikkim and Bhutan. R. oleifolium is the Chinese representative of R. virgatum. It should be noted here that in cultivation there are forms of R. racemosum, raised, I believe, from Wilson's seed, passing under the name R. oleifolium. They are not that species as described by Franchet. I assume that those writers who refer to R. oleifolium as hardly to be distinguished from R. racemosum, have in mind some of these forms of R. racemosum growing under the name R. oleifolium. True R. oleifolium is distinct from R. racemosum.

The name R. sino-virgatum was provisionally suggested by the late Sir Isaac Bayley Balfour for Forrest's early gatherings of R. oleifolium. This was before he had seen the type of R. oleifolium. After he had seen it he recognised that Forrest's gatherings were the same species as Franchet's R. oleifolium. The name R. sino-virgatum was never published, but by correspondence and the exchange of plants the name has got into use in some gardens. Plants in cultivation under the name are R. oleifolium, Franch.

A CLOSE ALLIANCE.

JUNE WORK AMONG CHRYSANTHEMUMS

THIS ARTICLE, FULL OF CULTURAL DETAILS, COMES AS A TIMELY REMINDER TO THOSE WHO WISH TO SUCCEED WITH "CHRYSANTHS" IN THE AUTUMN MONTHS

WHETHER the purpose in view is to furnish the greenhouse or conservatory, to enter the competitive arena of the November shows, or to ensure a bountiful supply of decorative flowers for cutting, June is an important as well as a busy month for the chrysanthemum grower. The plants are outside, not necessarily because the weather is so glorious that they will thoroughly enjoy every hour of night and day, but because, however rough the wind may be, however dreary the wet day, cruel the hailstorm or chilly the damp night air, the time of the year has come when a glass roof overhead will work havoc with chrysanthemums, drawing up the stems like attenuated rubber tubing, softening the foliage and then scorching it during the first hour of sunshine, and encouraging the rapid development of gnawing and sucking pests and fungoid diseases. Yet there are chrysanthemums to be found under glass in pits, and even in greenhouses, while the month of June drops its days one by one; it happens thus every year, and every year some chrysanthemums which ought to have been lusty, robust plants struggle through a painful, sickly existence.

SUMMER QUARTERS.

Southern growers may have got a good many plants into their flowering pots by June, but even so it is unwise to have them so early in their summer quarters; they should be given a brief spell under the shelter of the cosiest wall or, at any rate, in some place where winds do not punish them. By mid-June, however, it should, in all but notoriously rough quarters, be the aim to get the plants well out in the open, still contriving by some means to ward off the harsher winds, by the erection of a temporary screen if no permanent windbreak exists. Bear in mind that, generally speaking, it is not north winds that trouble British gardens in the summer months. In many cases, a garden that is well protected on the northern side suffers a great deal from strong south-westerly winds in summer.

Chrysanthemums must have air, light and sun, but they do not want roasting in July and August by standing on the southern side of a 10ft. brick wall.

It is unwise doggedly to determine to get all plants into flowering pots by a certain date. All varieties do not grow alike, and late struck cuttings are obviously not ready for final potting so early as those rooted in January and February. More harm than good will accrue from prematurely potting a plant in a 10in. pot which has not comfortably filled its 6in. pot, for the large body of soil does not, as novices are prone to imagine, encourage rapid growth. Of course, it is equally unwise to leave a plant to become badly pot-bound in any intermediary stage. Southerners can start potting about the end of May and finish by the end of June, while Northern growers should commence and finish ten days or a fortnight later. Plants for mid-winter decoration or cutting may be potted all through July.

A WONDERFUL PLANT FOR A FIVE-INCH POT.

STAKING.

Plants should be staked with at least one permanent full-sized stake as soon as potted up. Subsidiary stakes may be inserted round the edge of the pot at a later date, but the first main stake should be close to the main stem of the plant, and it is bad policy to begin with a 2ft. stick and then have to substitute it finally with a stout 5ft. or 6ft. cane, for such a task can rarely be accomplished without injury to roots or foliage, and frequently means limbs of brittle plants being broken.

Never be satisfied with one tie, but be liberal with raffia, so long as the ties are neatly placed and hidden by foliage. The raffia should be strong, and should first be tightly tied to the stake and then looped round the stem. Take care that the point of contact is midway between two leaf-joints, not resting upon an axil. Draw the ends of the loop until the raffia just touches the stem, then tie the knot. Allow no stem to be drawn from its natural position, and, above all, do not wind raffia round a stem to prevent its swelling in a natural manner.

Where a broad path runs north and south through a garden, the chrysanthemums may be placed in a single row along the side of the path. Allow all the room possible between the plants, and, at any rate, do not permit the foliage of one plant to touch another. The pots should stand on two battens with space between to admit of the free passage of water from the drainage holes and to prevent worms gaining access to the root-run. Some method must be adopted to prevent plants being blown over, and probably the best plan will be to run a taut, strong cable wire the whole length of the row, strained to firm uprights driven well into the ground and stayed at the foot. The tops of the stakes can be tied to this wire, and the plants will be safe. Circumstances do not always conform to our most ardent desires, and it may be necessary to run more than one row of plants, and these from east to west instead of north to south. So make the best of what cannot be avoided: and that will be done by keeping the rows as wide apart as possible, and placing the dwarf plants on the southern side, so that they are not shaded by the taller ones.

WATERING.

There may be nothing new to tell about watering, but there are a few points that, apparently, require eternal reiteration—they are so perpetually disregarded. A 10in. pot should have almost 2ins. of water-space to enable the whole body of soil to be moistened properly. If it can possibly be avoided, do not water with fresh-drawn tap water; even a few hours' exposure to sun in a broad, open-topped tank is of appreciable benefit. Whenever a plant has become so dry that the edges of the soil part from the pot, the plant ought at once to be freed from the supporting wire and immersed for half an hour in a tank. This is laborious work, but no other method is fully satisfactory. Some growers are immensely fond of daily overhead syringing: it certainly is a means of keeping the foliage clean, but it undoubtedly softens both foliage and stems, and that is not good for the plants. When plants get smothered with dust, a drenching sufficiently forceful to clean the leaves is necessary, but the water used should be tepid—indeed, almost warm. Apart from such a necessity, it is preferable to rely upon flooding the standing-ground on hot evenings, and occasionally to spray with an insecticide.

Digitized by Google

PESTS AND DISEASES.

Pests and diseases must have no peace. A nicotine wash is most effective as an insecticide, and sulphide of potassium is the best all-round fungicide for the rusts and mildews that worry unhealthy chrysanthemums; but bear in mind that the presence of fungus on chrysanthemums is evidence of erratic culture. Admittedly a few varieties are inherently susceptible to disease; they are the weaklings of the tribe, and are only tolerated because of exceptional beauty of their flowers. These, however, are not varieties for novices, but rather for experts who have little need of tuition.

FEEDING.

The common and usually common-sense maxim in regard to feeding plants is: Do not begin until buds are set; and some quite good growers adhere to this principle with chrysanthemums. There are two points, however, in regard to these particular plants which must not be lost sight of, especially by the exhibitor. A chrysanthemum makes a great deal of very substantial growth before it sets buds, and the plants have to be watered so frequently and so liberally that whatever nourishment there may be in the soil becomes excessively diluted, and to a considerable extent washed away through the drainage. Therefore the stems and foliage require nourishment, for without sturdy stems and big leathery leaves well built blooms are unobtainable.

The nature of the feeding in the early stages should differ from the later diet. Sulphate of potash is an excellent chemical food for stimulating strong, substantial foliage. Sulphate of ammonia and nitrate of soda both induce soft, flabby growth. Their only real utility is to give a fillip to a laggard plant, but the potash builds solid substance in leaf and stem. Soot water improves colour in the leaves; it is a moot point whether it really does more than that, but even this is useful, especially where some check has caused a pale, starved appearance in the leaves. Sheep manure is good for early feeding in liquid form, and it is better to ring the changes between the three than to begin with and adhere to any one kind of food. Weak and often is the golden rule in feeding. After buds are set a good proprietary chrysanthemum fertiliser should become the staple diet, still with an occasional change to a liquid animal manure.

PINCHING.

The exhibitor will have completed his "stopping" by the time this article appears in print, for April and May sees most of this work finished, although for mid-winter flowering a good deal later will be the time for final stopping. Pinching, however, is a task which must be carried out throughout the summer, as it involves not only reducing the "breaks" which are to be carried on, but pinching all the tiny young growths which break from the axils of the leaves, and which only inflict heavy labour upon the plant to supply them with nourishment that the important growths require. The proper method is to do a little pinching every day, never allowing a useless growth to become too strong to be cleanly removed by pressure of the thumbnail. Be always careful not to break or spoil a main leaf, for every one of these has its own functions to perform for the benefit of the plant. Disbudding is another matter, but belongs to a later period than this article is intended to cover.

A. J. MACSELF.

WELL-GROWN PLANTS OF CHRYSANTHEMUM SIR EDWARD LETCHWORTH.

GARDENS OF HEALING.—II

THE FOUR FLOWERS.

AMONG the many common plants whose healing properties are universally recognised in France there are four which are especially sought after. These are known as *Les Quatre Fleurs*. They are Papaver Rhœas, Verbascum Thapsus, Malva sylvestris and Viola tricolor. The petals and other parts of these plants are employed separately as medicines, but they are more usually mixed in equal quantities and used as *La Tisane des Quatre Fleurs*.

PAPAVER RHŒAS (the common red poppy; Fr. Coquelicot).—The narcotic properties of the poppy family are well known to everyone. They exist in the essences of the petals, which must be dried *very rapidly* and stored in a dry place. Opium is extracted from Papaver somniferum and should, of course, be only administered by professional people under doctors' orders; but an infusion of the capsules of P. Rhœas (three or four to a pint of milk) induces calm, refreshing sleep and quickly soothes toothache or neuralgia if applied *externally*. This is done by steeping a piece of flannel in the infusion until it is soaked and then wrapping it round the patient's head. This is applied to tiny children in France to induce natural sleep, and in cases of acute bronchitis, lung trouble and whooping cough a dose of infused poppy petals is given under doctor's orders. Dried poppy petals cost from 25 to 30 francs a kilo in France. The plants are very plentiful, but it takes a long time to collect a kilo of petals.

VERBASCUM THAPSUS (great mullein; Fr. Bouillon blanc) is still much used in some country districts in Britain. It is the plant *par excellence* for chest complaints, an ointment being made from its flowers which is undoubtedly of great value. On the Continent it has a great repute, not only for the above maladies, but also as a cure for all rheumatic and gouty disorders. For this purpose the root of the mullein is dried and cut into rounds, which are made into a decoction which is taken three times a day. A gentle laxative and a blood purifier is made from the flowers of this plant Its leaves boiled in milk are used in France to cure phlebitis and to heal cuts and burns.

Verbascum Thapsus is a magnificent plant, and 1½yds. should be allowed between the plants for the full development of the branches. The flowers should be gathered and dried *in the sunshine* and handled as little as possible. They must be stored in a dry place.

MALVA SYLVESTRIS (common mallow; Fr. mauve).—The seed vessels of the common mallow are wholesome and allay irritation owing to the mucilage they contain. This "stickiness" is what make them so beloved of English and French children as "cheeses," or *petits formageons*. The whole plant cures colds and coughs and produces expectoration. For colic and internal complaints the soothing properties of its leaves are used. An infusion of these is a sovereign remedy for dysentery not only on the Continent, but also in Egypt, where it

Digitized by Google

grows abundantly and where in Arab houses the whole plant is highly prized as a vegetable and is cooked like spinach. To allay irritation in rash diseases or to stop tickling in the throat an infusion of mallow leaves is used. Poultices made from the fresh root are applied to boils and gatherings, and a *very* hot one quickly relieves the pain of violent gout.

VIOLA TRICOLOR (pansy).—"Tisane des Pensées" is a popular and much-used remedy in France for all skin diseases. For several weeks a cupful is taken three times a day. Dried pansy leaves reduced to powder are put in the food of French infants who are inclined to eczema. The fresh leaves are a laxative and when dried are used to allay feverishness from whatever causes it arises. Pansy roots reduced to powder are beneficial for emetic purposes.

The petals of these four plants mixed in equal quantities form a household medicine in France which can be safely given to anyone. It is laxative, soothing, a blood purifier (hence it is anti-rheumatic), a preventive of coughs and colds, and allays feverishness. It is easily made at home, and is an absolutely safe remedy. It is astonishing that so efficacious a medicine is unknown in England.

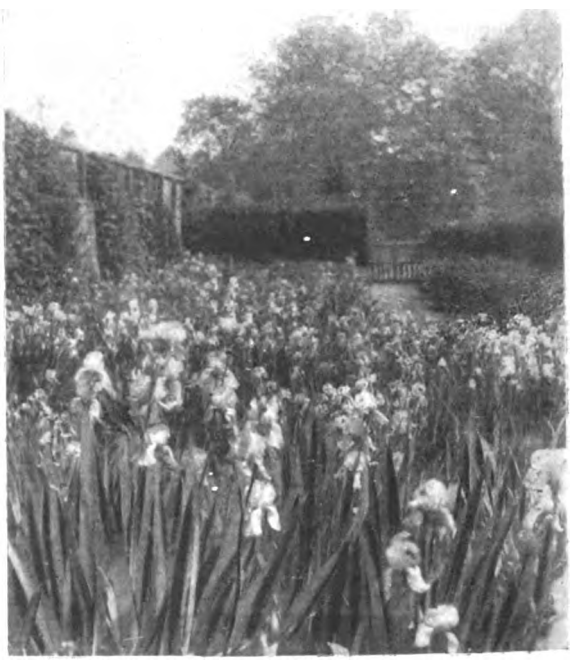
VICTORIA SLADE.

FRAGRANCE IN THE SUMMER GARDEN

SUMMER with its increasing light and heat is so full of flower perfume that when one begins to consider it, the impression is apt to be rather a medley, but a little more leisure will suffice to disentangle this and one of the first things to emerge is the garden pink. Would that we could cull afresh one's first impression of this generous flower. That one might once again gather and inhale one's first breath of this inimitable perfume. That, alas! is beyond our powers, but we may renew the pleasure annually and, having renewed it, retain it for many weeks by growing as wide a range as possible of the varied species and varieties that possess this gift. The pink is a plant that has fluctuated in popular favour and recent years have seen many remarkable fresh developments, but, when one casts back to forgotten years, one discovers variety after variety, now lost to cultivation.

Old volumes of the *Botanical Magazine* will reveal some astonishing mathematically marked and coloured varieties, and one cannot but help wishing that once again these might come to life and reveal whether they too were notable for distinct perfume. It is certain, however, that our present day varieties are not lacking in this respect and, right up from the lowliest of alpine forms, such as fragrans, to the lordly carnation itself, we may follow a perfumed pathway of tremendous attraction. And what magnificent garden plants they are too! How generously and gorgeously they flower with an inimitable wealth of colour and a habit that leaves nothing to be desired, while even in the depth of winter they still furnish a splendid touch of colour by reason of their evergreen and ever-grey leafage.

Everyone who seeks perfume in his or her garden will be certain to make the most of the old-fashioned deep red clove carnation, probably the sweetest of all and the most powerful too, but July and August provide such a welter of their gorgeous blooms in such a variety of colours that it is almost impossible to particularise. Of course they have rivals,



A FINE BORDER OF JUNE-FLOWERING IRISES.

and the mention of the word "lily" will focus the attention upon another race of plants that are famous throughout the world for the vigour and distinction of their perfume. All through the summer days, from the time when the first bloom of candidum expands, right up to those cooling autumn evenings when the latest blooms of speciosum are flourishing, a procession of delightfully perfumed lilies is with us, though this probably reaches the zenith of its power in August when the wonderful auratum is carrying its immense head of giant blooms. This is essentially an outdoor flower, for, if it is cut and brought into the house, the strength of the odour is apt to prove overpowering, but, in the open air, diluted by the warm atmosphere, one's sense of smell is pleasantly tickled.

Earlier in the season the place occupied by the lily in late summer is filled by the iris, and all through May and part of June the garden that is planted with a rich store of these is painted with vivid splotches of colour, some notable for the rich depth of their brilliance, others æsthetic in their quaintness, while others are just simple delicate tones that blend and harmonise with anything and everything. It is a wise gardener, indeed, who places his chief reliance on these "selfs," leavened by a few of the more unusual and striking kinds. Almost all irises have the grace of perfume, a remark that is true both of the tuberous and bulbous rooted forms. Among the latter the Spanish varieties are pre-eminent, and one would be hard

PEONIES ARE INVALUABLE IN THE SUMMER GARDEN.

Digitized by Google

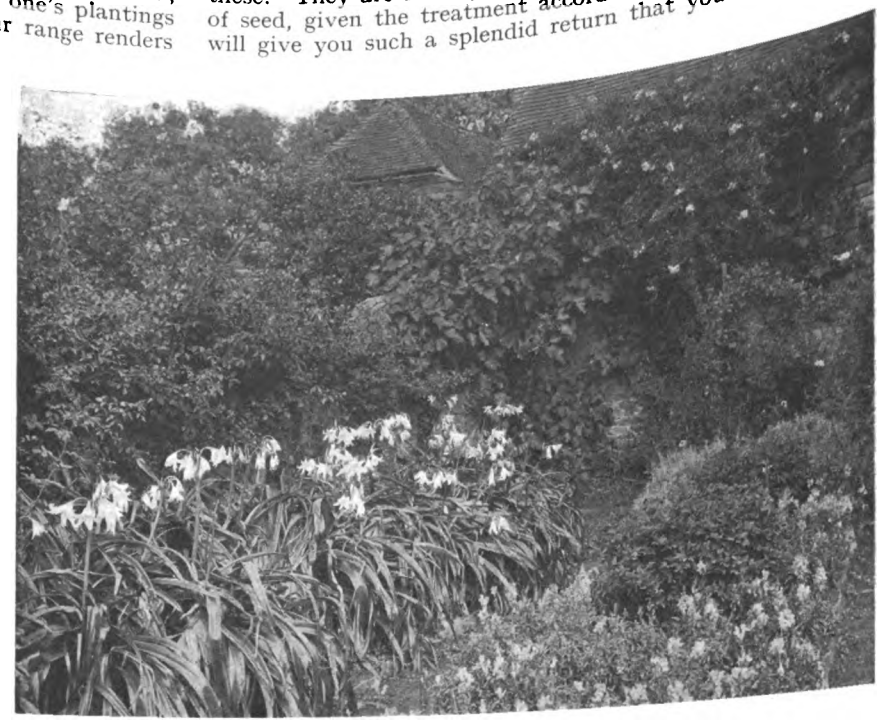
to make choice of a more beautiful race for extensive planting. They are useful alike in the large or small garden; it is only a question of adjusting the scale of one's plantings to suit the area at command, while the colour range renders it easy to choose varieties which are suitable for every conceivable requirement.

Mention has been made of the germanica section as particularly fragrant and, to these, we may add all the pallida class, while a similar label may be attached to I. florentina. The flowers of this are white slightly tinged with blue; while the falls are distinctly marked by a bright golden beard. I. Monnieri is very distinct, with handsomely formed bright golden flowers that are powerfully scented. Among the lesser known iris is sambucina, a very vigorous grower, running to 3½ft. The flowers are yellow with brownish-violet rays and veins, and a bright yellow beard, the whole strongly perfumed after the manner of the elder blossom. An old-fashioned flower, that looks like recapturing some measure of its former popularity, is the rocket. This in its best and double form rather resembles the stock, with white or deep purple flowers in early summer. These double varieties are readily increased by means of cuttings, though it will sometimes be found possible to divide older plants. Cedronella cana is worth noting as an aromatic plant that is quite effective in the borders and bears crimson purple flowers.

In late summer and autumn, the herbaceous phloxes make a display that for sheer gorgeous effect cannot be equalled, while they fill all the air with a perceptible perfume that becomes stronger and stronger as the sun becomes hotter. Indoors, where they are used as cut flowers, one is indeed aware of this, while the fragrance never becomes so strong as to be unpleasant. Especially choice for well drained and well sheltered borders are the crinums, a bold genus of lily-like plants with handsome deep green strap-like foliage and large umbels of pink or white flowers which are deliciously fragrant. These flowers are funnel-shaped and widely expanded at the mouth and no fears need be entertained as to their hardiness, over the southern half of England at any rate, while, farther north, a covering of straw is sufficient to ensure their safety on all but the coldest soils.

One does not meet the libertias so often as one could wish, but they are grand summer flowers and possess a fragrance that is all their own. There are two varieties, the dwarf and the tall, L. magellanica and L. ixoides. The former does not exceed 18ins. in height, with pure white flowers arranged in heads and packed very closely together; the latter somewhat resembles an iris in habit, reaching a height of 3ft. or 4ft. with heads of white flowers which are made more conspicuous by the mass of yellow stamens at the centre. The dwarf variety is much the better of the two and provides excellent material for cutting. For broad edgings, Calamintha alpina is a splendid subject that is useful in every way. Not only is the whole plant aromatic, but it forms a close mat of leafage and bears charming sprays of violet flowers that are in evidence through almost the entire summer. One of its chief points is that it provides an ideal setting for other flowers, a fact that is strikingly emphasised by associating with sweet williams. The soft hues of the calamintha serve to emphasise the glory and brilliance of the heads of sweet william and one procures, too, a combination of perfumes, the aromatic qualities of the calamintha with the sweetness of the sweet william heads.

Verbenas are another glory of the summer garden, and, both on the score of perfume and brilliant show, it would be very difficult indeed to discover anything that would outclass these. They are so easy to manage, too, and a mixed packet of seed, given the treatment accorded to half hardy annuals, will give you such a splendid return that your love for their



FOR WELL-SHELTERED CORNERS THE CRINUMS WITH THEIR HANDSOME FOLIAGE AND CLUSTERS OF WHITISH TO PINK FLOWERS ARE ESPECIALLY SUITABLE.

VERBENAS HAVE A CHARM ALL THEIR OWN IN THE SUMMER GARDEN.

special fragrance is likely to deepen and you will repeat the sowing year after year. Among the commoner plants, Centranthus ruber is a sturdy specimen that will begin to flower early and continue late, indeed, it is seldom that one will go to the plants during the summer months and fail to find a lavish display of the honey-scented reddish sprays that are so effective. This is just the plant for out-of-the-way places where the soil is shallow or poor in quality, for, where found as a wilding, it is generally on the steep face of a cliff, railway banks or some other similar position, and no one would be likely to complain of its flowering under these conditions.

Peonies vie with the rose in deliciously delicate fragrance, while the best varieties are not one whit inferior in the charm and delicacy of their petal formation. This is a flower that

Digitized by Google

conquers all who love a garden, whether their love originates in admiration of beauty of form or of colour, fragrance or daintiness or any other charm that flowers can provide. Passing from their splendid size and handsome leafage to the most modest flowers, do not let us forget the violet—grown entirely outdoors and allowed to flower just when it will. By all means have your frames for winter supplies, cover some plants with a handlight, if you wish, but do not omit some well grown clumps of the finer kinds, tucked in here and there in the general borders and allowed to peep forth their delicious double and single flowers, as and when they will. It is astonishing at what varied seasons they will do this, as though to serve as a reminder that other days and other seasons are coming or have passed. In winter they are heralds of the coming spring. In summer they are lovely waifs, born out of due season and therefore commanding our respect. In autumn they are a reminder that even the fairest may be deceived and that like conditions may provoke a response when things are not what they seem. In spring they are just their own true delightful selves, brimming over with the message that now, indeed, has new life returned to the sleeping earth. Upon only one point must one be careful with these outdoor grown plants, they must be well watered and syringed or red spider will seize upon and utterly ruin them during the heat of July and August.

Another important family of plants for the lover of fragrant flowers is that of the lupins. These have provided us with many a startling surprise of recent years, so that our old friends, the typical blue and white forms (that, it must be admitted), used to shed their unopened buds rather badly, seem a very long way away. But it is quite one thing to add or mix colours and quite another to produce scent, though this is what has happened in the case of the Six Hills hybrids. These have every shade of colour that the most inventive mind could imagine, as well as a perfume that carries for some distance round the plants.

Dictamnus fraxinella makes a double appeal, for not only does the plant exude a strongly perfumed resinous oil and therefore come within the scope of our present thoughts, but it is also a very showy border plant. The height reached is between 1ft. and 2ft., so that it must not be placed too far back in the border, while it flowers in early summer in long terminal spikes of light purple flowers. It is sometimes called the Burning Bush from the fact that if a match is struck near the plant in the evening of a hot day, the gaseous vapour will take fire, but it seems to be a fact that, in this country, at any rate, we do not get sufficient warmth for this to be possible. Apart from that, however, it is a useful and showy plant that makes a great display on the margin of the shrubbery; there is also a white variety. Monarda didyma—Cambridge Scarlet—is worthy of high praise, both for its whorls of scarlet flower which make such a brilliant show in the garden and also its distinctive honey-like perfume that is not too powerful. It will literally "grow anywhere," but merits good soil, as this enables it to reach its fullest stature and thus make the most imposing display.

One must, however, conclude somewhere, and this already lengthy note may be brought to a fitting conclusion by mention of Malva moschata, the musk mallow. In this instance it is the leaves that are responsible for the famous musk odour. It loves a well drained and chalky soil and, when happy, reaches a height of 2½ft. The flower spikes, which appear in summer, are pale rose coloured and very showy, for the individual flowers of which it is composed often measure nearly 2ins. across.

H. W. CANNING-WRIGHT.

TREES OVERHANGING GARDENS

LOPPING RIGHTS AND RESPONSIBILITIES.

ADJOINING OWNERS AND OCCUPIERS

THE lopping of overhanging trees belonging to adjoining owners and occupiers is a subject upon which many words have been spoken and many friendships broken. To the most peaceable of neighbours the question has been, and no doubt will continue to be, a frequent cause of irritation and trouble. The ordinary individual knows little or nothing of the actual law in these matters, and, if acquainted with one side of the subject, fails to understand another, so that any step taken is as likely to be the wrong as the right one.

AN APPLE TREE CASE.

This was clearly demonstrated quite lately. The Plaintiff had his apple trees growing within a few feet of the boundary running between his own land and the property of the Defendant. These trees bore a popular class of apple, and the branches of the trees overhung the Defendant's land, to his great annoyance apparently, for he maintained that he was justified in taking action. But the Defendant claimed that not only could he lop off the offending branches, which he, in fact, did, but that he was further entitled to pick off the apples growing on these branches, and this he also proceeded to do. The quantity thus picked ran into some bushels, which the Defendant subsequently sold. The Plaintiff then started proceedings against him for conversion, in the County Court. The judge of that Court held that, while a nuisance may be removed, a person is not entitled in appropriating and converting to his own use or benefit that which caused the nuisance, and judgment was, therefore, given in favour of the Plaintiff.

THE HIGHEST AUTHORITY.

But the Defendant was not satisfied with this decision of law and appealed against the finding. From the judgment given in the case in the High Court some useful object lessons are to be gathered, if the important points which are relevant are carefully taken into account. Some sides of the whole question were, in fact, closely examined a good many years ago by our highest legal tribunal—the House of Lords. In the case then considered some rather large and old trees overhung the Respondent's land and had so done for more than twenty years. The Respondent gave no notice to the Appellant, and did not trespass on his property, but he cut off a number of the branches to the boundary line. It is an accepted principle of the law that a person shall not go upon the land of another to remove a nuisance, unless it be a matter of necessity, until he has taken the step of giving the other person reasonable and proper notice. The reason of this is that such an act is an interference with the soil of that other person, and this amounts to a trespass in the eyes of the law. It is true that this was a point which did not primarily emerge from the House of Lords case, where the leading question was whether or not a notice was necessary before the overhanging branches were removed. But the House of Lords decision is valuable because it settled the law that such a notice was not required. The House of Lords, however, had the further question before them as to whether or not the Appellant had acquired any right which arose from the length of time the trees had overhung the Respondent's soil. Their opinion on this point was that it was impossible to say that the Appellant had acquired a right to the land over which the trees were hanging, or to their overhanging, either under the Statute of Limitations or under the ordinary law of prescription The House of Lords took the view that if a person can manage to get rid of the interference or encroachment of overhanging branches, without committing a trespass upon his neighbour's land, or entering upon it, this act clearly can be done, and that the right can be asserted whenever it is deemed proper to exercise it, while no notice or previous communication is required in such a case. But the question was not considered, for the purposes of a decision, whether this rule was one which would necessarily apply to the cases of trees so young that the owner might remove them intact, if he chose to lift them, or to shrubs capable of being transplanted, although it was recognised that this question was worthy of examination. In the case of recent date, already mentioned, this well established case in the House of Lords was, of course, referred to.

DECISION IN RECENT CASE.

In the recent case, if it had depended upon the nuisance created by the overhanging branches, the Defendant was obviously entitled to abate this nuisance, but his right was restricted to this. It

Digitized by Google

ance, and did not justify him in further, in this particular appropriating to himself either the offending branches when cut off, or the fruit which was on them. This was the Plaintiff's property before being severed, and the High Court held that it remained so afterwards. In deciding for the Plaintiff the Court took the view that he had the right to possession of his property, but did not indicate the means by which they thought the Plaintiff, in such a case, could have properly enforced this right, if the Defendant had, in fact, merely severed the branches and done nothing more. But the Defendant had appropriated the property to his own use by selling it, and consequently conversion arose. Had he simply cut down the branches it would appear, however, that the Plaintiff could have recovered his property by proper legal proceedings, if delivery, upon request, had been refused. As it was, the Plaintiff was entitled to the value of the property. It may be added that the Court considered the same principle applied to apples which might have fallen, or have been blown off, when they were on the Defendant's land.

A LAWYER.

THE ENEMIES OF THE STRAWBERRY

OWING to their habit of growth, strawberries are peculiarly exposed to the attacks of the various hungry enemies living in and upon the soil beneath them, as well as to damage from such foes as invade fruit trees and bushes.

Slugs, millipedes, eelworms, wireworms, and other grubs, as well as surface caterpillars, attack root, leaf and stem. Mice and frogs can approach the fruit without difficulty, while from above it is equally discernible to birds and other winged assailants. Even the flower suffers from the epicurean tastes of one marauder —the beautiful rose chafer, whose grub thrives upon the roots.

It is well if these same roots are at first numerous and healthy; for the grubs of the cockchafer, rose chafer, click beetle (better known as the true wireworm) and crane fly (leather jacket), as well as the millepede or false wireworm, will one and all find a satisfactory living upon them should these pests reach their vicinity.

Hence, if any manure or earth has to be added to the strawberry bed, it is advisable to make sure that it is free from injurious creatures—by such methods as frequent turning to expose it to the researches of the birds, the admixture of nitrate of soda and soot to make it unhealthy for intruders, or watering with a solution of salt for the same purpose.

The grubs of the cockchafer and rose chafer are much alike, the principal difference being that the rose chafer grub has a brown spot on each side of the segment or ring next its head.

THE LARVA AND ADULT OF THE ROSE CHAFER.

Both of these grubs feed upon strawberry roots. They are peculiar in shape, having a tough-skinned body, the tail end of which is permanently bent underneath it. The eggs are laid in clusters in summer, in earth or old manure heaps, and are best dealt with by digging, followed by hand-picking or birds.

The cockchafer is a heavy-looking insect with brown corrugated wings, two species of which are well known as the May bug or June bee.

The rose chafer is a handsome beetle, green above and copper coloured beneath, with a pinkish tinge. Its grub measures about 1¼ins.

The wireworm is a grub of a different calibre. As its name denotes, it is of a wiry appearance, thin in proportion to its length. It has six very small legs and is orange in tint. It is supposed by gardeners to feed on almost every kind of root, with the exception of mustard, which it cannot tolerate and which is sometimes grown and dug into the earth as a preventive against its mischievous practices. It lives from three to five years in the larval stage, then pupates and hatches into a click beetle, so called from the noise made in recovering its feet after having fallen on its back.

The millipede, or false wireworm, is not an insect and does not change its form, except to become longer and larger. Its legs are very numerous and look like hairs and it may be known by these and by its habit of coiling like a watch spring when touched.

The body of the leather jacket is softer, with a tough skin of dull brownish grey. It feeds on the roots of grass and other plants in a very destructive fashion. The eggs are laid in summer and early autumn, hatching in a couple of weeks to the grubs, which feed till the next spring or beginning of summer, when they pupate.

From June onward the pupæ, one by one, work themselves partly out of the ground and hatch into the crane that fly, we know so well as "Daddy-long-legs." As the grubs thrive in wet soil, infected areas should be well drained and, when possible, thoroughly dug over, when starlings and other birds will generally search out the grubs very thoroughly.

In dealing with grubs and millepedes the surrounding soil should be dressed with something harmless to the plant whose health is in question, and injurious to the foes likely to attack it. Among these remedies lime, or nitrate of soda, and soot may be used with care, or land may be prepared for planting by using stronger applications. If large quantities of Vaporite be used some months must elapse before planting is safe.

The leaves of the strawberry suffer from the onslaughts of a variety of foes. Among these slugs are very prominent. The habits of these unassuming but voracious pests are largely nocturnal and a good addition to any remedial measures will be to examine the beds after nightfall, with the help of a torch, and the accompaniment of a pail of insecticide wherein to drop the bodies of the intruders. Soot and lime left on the surface round and between the plants are most useful, but the straw which is placed between the rows before the fruiting season forms a dangerous harbourage for these little foes and one difficult to keep free from them.

The strawberry snail (Helia rufescens), is another insidious enemy which also feeds upon the iris and violet and may infect the strawberry from such sources. The egg of rufescens should be sought in late autumn and may probably be found beneath the surface of the soil.

Many strawberry leaves are dappled with brown spots, which are the work of the fungus Sphærella fragaria. In mild attacks this does not greatly affect the fruit-bearing capacity of the plant, but in the autumn it is better to clear away all dead leaves, cutting off those affected; also to examine

LEAF SPOTS CAUSED BY SPHÆRELLA FRAGARIA.

the plants in spring to see that they are practically clear.

For strawberry mildew (Sphærotheca castagnei Humuli), which is white and attacks the under surface of the leaves, causing them to curl, a fungicide should be applied before the fruit is formed, if the condition be recognised early enough, both to save the possibility of the fungus attacking the fruit and to guard against any danger from poisonous applications.

Sulphide of potassium in the proportion of about two teaspoonfuls of the powder to a gallon of water is a useful fungicide needing careful mixing, using a small quantity of water at first, with the remainder added by degrees or the powder may float on the surface.

Leaf and stem are sometimes infested by eelworms of several species which injure the health of the plant, and sometimes cause the disease known as "cauliflower," a thickening and amalgamation of stem, leaf and flower, only to be met by consignment to the fire of the plant (or at least the part) affected. The length of the eelworm is but a twenty-fifth of an inch or under; its presence being judged by abnormal growth of leaf or flower buds. The infection for this pest is from the soil and remedies are the same as for grubs.

The blossoms of all outdoor fruit undergo some uncertainty as to whether they will be able to escape accident and damage from frost, but some, the strawberry among them, are subject to another mischance, the ravages of certain insects which have acquired a taste for their stamens. The rose chafer acts as a burglar to the strawberry blossom, robbing it of the anthers

Digitized by Google

on which its fertilisation depends, and leaving its fructification to chance and the roving bee.

The fruit itself is eagerly sought by birds, but very largely to allay their thirst. If owners of strawberry beds will have flower-pot saucers filled with water constantly renewed, placed either among the fruiting plants, or very near them and plainly to be seen, they will find it makes a very great difference to the loss of fruit through birds, as it is often thirst and not hunger which occasions their depredations.

Mice are troublesome sometimes, but chiefly in eating off the achenes, or seeds, which decorate the outside of the fruit. Cats and traps are, naturally, the remedies for such raids; but, unfortunately, the ground beetle Harpalus has the same habit and is not so easily dealt with. For it, jars may be sunk in the earth and filled with sugared water in which a few small pieces of meat are floating. It should, however, be remembered that the ground beetle lives on caterpillars and other insects and so should not be disturbed unless really troublesome.

If the plants are not properly supplied with straw, millipedes may attack the fruit, eat out a hollow, and curl themselves inside, a most objectionable proceeding. M. L. BROOKE.

NOTES FROM CONTRIBUTORS

PRUNUS SUBHIRTELLA AUTUMNALIS

A VERY delightful and perfectly hardy plant is the so-called autumn-flowering cherry, with its wealth of pink, semi-double flowers. As a rule it is a much branched bush anywhere from 8ft. to 15ft. tall, with slender, ascending, wide-spreading branches; occasionally it is a small tree. In the park at the old eighth century capital of Nara in Japan I have a note of a tree 20ft. tall, with spreading branches and a well developed trunk 2ft. in girth, which in the early days of December, 1914, was gay with flowers. But the plant does not always flower in the autumn. Sometimes it flowers in the spring, and is then called in Japan the Yaye-higan—that is, the double-flowered spring cherry. The more usual name applied to it, however, Jugatsu-zakura, which means the tenth month (October) flowering cherry. From what I learned from Japanese horticulturists, it is apparent that when this cherry is well covered with flowers in the spring the flowers are few in the autumn and *vice versa*. It is evidently a very precocious plant that does not obey the ordinary rules as applied to flowering seasons. With its elegant habit and wealth of charming pink blossoms it is truly a delightful plant. Since its own flowers are semi-double the autumn cherry rarely produces fruit, but it may be propagated from cuttings and also by grafting on seedlings of the rosebud cherry (Prunus subhirtella pendula).

A comparatively recent comer to Western gardens, it has been long cultivated in Japan, where the accompanying photograph was taken in the spring of 1914.—E. H. WILSON, *Arnold Arboretum, Harvard University*.

A DOUBLE FLOWERED CHERRY FROM JAPAN.

CLIVIAS.

THESE evergreen flowering plants appear to be increasing in popularity every year, and, like the vallota, this is probably due to the fact that when not in bloom they possess a certain value for indoor decoration. Those who grow clivias know very well that they are not over particular as to quality of soil, but they do best when treated in a generous fashion, and, given a compost of fibrous loam and leaf-mould with charcoal added, they will go—and are often allowed to go—years without being re-potted. It is unwise, however, not to shift them occasionally, as if left too long separation, or division of the roots, becomes well nigh impossible. With the advent of February they commence to grow and bloom, and from May onwards until early autumn, it is scarcely possible to give them too much water. Clivias will give a good account of themselves in any temperate house, and really require nothing in the way of heat, beyond being kept from frost. The first flowers, which usually open early in February, are paler in colour than those which appear a month or so later, the reason being that sun has an effect on the intensity of tint in subsequent blossoms. Of the three species—nobilis, Gardeni and miniata—the last seems to be still as popular as any; certainly it is more often seen, but we have numerous hybrids, some of which are very charming. Where it is desired to increase the stock of clivias, it is best done, I find, by off-shoots or division—more readily, indeed, than by the slow method of raising plants from seed, hence the advisability not to permit plants to become conglomerated at the roots, which spells trouble sooner or later.—W. LINDERS LEA.

ŒNOTHERA MARGINATA.

NOMINALLY an easy plant to cultivate, there is yet a wonderful diversity of experience respecting this inexpressibly beautiful flower. It has ways of its own, foibles we are apt to call them, but it is far from easy to discover what they are and how to humour them. Some appear to experience no difficulty with the plant, others find it short-lived; some think it easy in its demands, and others are of opinion that it is rather too delicate for our climatic conditions. But Œ. marginata is such a lovely flower and has such transcendent attractions that there are few who see it who are not eager to possess it.

What the end may be it is difficult to tell, even if the most approved methods are followed in its treatment. The writer has known many plants of this exquisite Evening Primrose in many gardens, and has grown not a few himself, but, in the long run, he has come to the conclusion that it is not usually a long-liver unless it can be left greatly to its own devices and allowed to send out its suckers to find "fresh fields and pastures new," and thus keep itself vigorous and robust. When such giants among plantsmen as the late Mr. Reginald Farrer have written it down as "delicate," one may venture to say this much at least. The finest plant I ever had was growing at the base of a sunny part of the rock garden, and was bounded on the south-west by a very narrow gravel path. This plant flourished admirably and flowered well for some years, and then started to send out suckers to the other side of the narrow path. This seemed to afford an excellent opportunity for propagation, so the suckers were taken off and planted in pots. The following spring the old plant had disappeared, dying, probably, from exhaustion. The methods of propagation, by means of the suckers and cuttings, are quite good; but if the former plan is accompanied by the loss of a fine mature plant, one cannot but regret the result. A good plant is of rare beauty, with its handsome leaves, its low, trailing growth and its wondrous, lustrous white flowers of great size and marvellous charm. The blooms open in the afternoon with virgin purity and gradually change in colour, remaining open all night and appearing in the morning a delicate rose colour, but shorn of their loveliness of the evening before. Undoubtedly, a light, sandy soil is best for this delightful evening primrose, and I consider that it should be made rather firm and that some porous stones should be about its roots as well.

A flower of such gracious beauty is well worth any effort to cultivate successfully, and even its possession for a year or two will leave a fragrant memory which will linger with us for many years.—S. ARNOTT.

SIMPLE GARDENING

COLD FRAMES IN SUMMER.

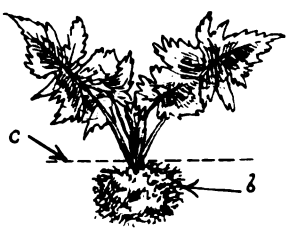
THESE may be regarded as miniature greenhouses by those persons interested in plants generally but who do not possess a real greenhouse. Those who enjoy the latter usually make good use of the garden frame too. The cold frame may be looked upon as the feeder of the greenhouse, as the small streams are protected which act as feeders of our canals. Personally, I always enjoy growing such plants as primulas, cyclamen, cinerarias and calceolarias in a frame or frames placed to face due north during the summer months. For the benefit of these and other plants that like cool conditions, a nice bed of old, clean ashes is essential. When a cold frame faces due north with the high back to the south, there is not the same need for shading as when the frame faces south. The plants really have more light in the north aspect because the glass lights need not be heavily shaded on the hottest days. Now, as to placing the plants in the frames. The calceolarias should be right at the back, where least sunshine penetrates, but all the other kinds should be equally disposed in rows from front to back—to the calceolarias if the latter are grown. If plants are not grown, then some vegetables and salads may be cultivated, the foremost being frame cucumbers. A novice should try a few plants of ridge cucumbers in a cold frame, as it is wonderful how well they succeed in it. Make a narrow pit along the front of a frame, inside, fill with good compost, firm it and plant several tomatoes, training them to long stakes 1ft. from the ground. Very good crops may be grown. Fill the cold frames in summer. Do not allow them to remain empty and, probably, harbouring weeds.

OVERCROWDING PLANTS: OVER-CROPPING FRUITS.

We often err in leaving too many plants in pots, pans or borders, or too many fruits on the branches, because we have them and do not like to lose any. This happens even when we know that the results will be unsatisfactory. A noted grape-grower, in long ago days, said he could never bring himself to the decision to thin out adequately both bunches and berries without a struggle with his feelings. "The best thing to do," he said, "is to bring in one of the labourers and tell him to cut out so many bunches, and then leave him to the task," but even this course required courage, which he did not possess. Probably annuals are left by us generally in the most overcrowded state of any plants in our gardens. Sweet peas, culinary peas, beans and root crops come a close second. If we thin out while the plants are small, we do the right thing and rarely miss them, whereas if they are left to form a jungle, we do not know which are the best to leave, and the best of them at this advanced stage are poor, rendered so by undue overcrowding. In our greenhouse we may have two hundred plants, but there is, really, only proper space for one hundred, which, if given fair play, would make the bravest display in the end. The properly thinned bunch of grapes looks rather a poor specimen, but in a month's time it is splendid. It is not often that we trouble about thinning out our hardy fruits, but it sometimes proves very beneficial. We should, when reducing numbers, realise in our minds what the fully grown specimens should be like.

PROPAGATING DOUBLE-FLOWERED PRIMULAS.

The Chinese double-flowered variety is still grown in many gardens where pure white flowers are required over a long period for nosegays in winter and spring, and pyramids of snowy blossom, rising from a cushion-like base, are appreciated in the warm greenhouse.



But I find that numerous new cultivators are at a loss as to how they should treat the old plants when the flowering stage is past—in June. Seeds are not sown, but layers are rooted almost after the way of layers of border carnations. The old plants should be placed in a cold frame on a bed of ashes, preferably in a frame facing due north, or in one on the north side of a wall or fence. Sufficient water should be given just to maintain the freshness of the leaves, not more. Very carefully clear away any faded basal leaf-stalks and weeds. Then mix sandy loam, leaf-soil and sand in equal quantities and fill up the pot with the compost, piling it high enough to bury the base of the side shoots and lower part of the parent plant. Do not destroy any side shoots at the base when cleaning old plants. Cover the new soil with green moss and maintain the latter in a moist state. When the side shoots possess roots, detach them and pot into small pots, then shift to larger ones in due course, adding a little dried cow-dung to the compost. The letters *a*, *a*, point to the young basal side shoots; *b*, rooted side shoot; dotted line *c*, depth to pot.

AUBRIETIAS, PRIMROSES, VIOLAS.

The aubrietias have, in particular, been very beautiful this year and delighted the hearts of rock gardeners especially. Some amateur cultivators think the only means of increasing the number of plants is by division or the insertion of cuttings. Of course, the neat division of nice fresh clumps is a good way, and succeeds, but seeds may also be sown now and a good batch of healthy young plants secured in time for planting in due season. The aubrietia will grow in any rockery position, but best in one facing south, east or west, although the colours of flowers in northern aspects are generally very deep. The seeds should be sown in pans or pots in preference to boxes, filled with a good open compost. Although the plants will grow in any ordinary garden soil, for the benefit of the seedlings I like to add some tiny lumps of old mortar and some pounded bricks, also old ones. The drainage should be sound, as the young plants do not thrive in a sour soil. The seeds are small, so it is advisable to prepare a level, smooth surface, to scatter the seeds thinly and barely cover them, but press the surface a little to embed them into the soil. Cover with glass and paper and keep the seed vessel out of the direct rays of the sun for a time. Primrose seeds should be sown just the same as those of the polyanthus, and the resultant seedlings should be transplanted at an early stage in a cool, prepared bed. At this season I like such beds better than dry boxes. We all know how lovely violas are, especially those of choice strains. It is to these I now refer. Turn an ordinary garden frame towards the north, make up a nice bed of loam in it, sow the seeds thinly in shallow drills and do not shade, let in all the north light and treat the young plants well. GEORGE GARNER.

Presentation to the Rt. Hon. Sir Herbert Maxwell.—At a dinner given in honour of Sir Herbert Maxwell, Lord Lieutenant of Wigtownshire, at Newton Stewart, on the 16th ult., the occasion was taken to offer him tokens of esteem and affectionate regard from every corner of Galloway. As our readers know, it is given to few gardeners to "ruminate in print," so gracefully, and withal to such practical effect, as Sir Herbert Maxwell. His writings are the outcome of a gardening experience extending over more than half a century, and though the climate of his ancestral home on the shores of Luce Bay is so mild and humid as to enable Sir Herbert to grow many sub-tropical plants, denied to less fortunate folk, the latter can seldom read what Sir Herbert has to say about his garden and the many friends in it without deriving therefrom something of practical instruction as well as much refreshment for the mind.

NAMING OF NEW ROSES

[The following has been sent in by a correspondent and is a translation of an article in the French publication, *Les Amis des Roses* (the official journal of the French Rose Society).—ED.]

WE are pleased to inform our readers of an interesting communication which we have received from Mr. Nicolas, the sympathetic secretary of the American Rose Society. We take this opportunity of expressing our sympathy to this American society, and offer our best wishes for its prosperity. Furthermore, we recommend our members themselves to become adherents of this grouping. (See our reports.)

The aims of the Registration Service of the American Rose Society are :

1. To prevent the use of a name already given to a preceding rose.
2. To simplify names and avoid superfluous titles.

We cannot do better than quote Mr. Nicolas :

" As the name of a rose cannot be patented, our service makes up for this deficiency. Naturally, we have no legal authority to prevent a grower from naming a rose as he likes, but he could not take part in the competitions and exhibitions organised by the A.R.S.

" When a name is put before us, we immediately advise your Society, and the National Rose Society of England, as well as the Australian Society and the Nos Jugunt Rosae of the Pays-Bas. A period of three months is allowed to make the necessary investigations.

" The recent regrettable confusions demonstrate the necessity for an *entente*. Nowadays the rose is international, and needs to be protected. In fact, when two flowers bear the same name, they cannot enjoy a great popularity by reason of the inevitable confusion. Buyers hold back because they fear they will receive a yellow rose when they want a red one, or *vice versa*.

" Another aim of the A.R.S. service is the adoption of names which are as simple and short as possible and easily pronounced in all languages. Names which are too long are an obstacle to the popularity of the rose. It is thus that those two remarkable roses from all points of view, Souvenir de Claudius et de Georges Pernet, are known here under the names of C. and G. Pernet.

" As to that equally interesting variety, Souvenir du Capitaine Fernand Japy, it will be difficult for this to penetrate into America solely on account of its long name."

The Société Français des Rosieristes can but associate itself with this request. The Society will be pleased to give the American Rose Society all possible information when the occasion arises. In acting thus we shall serve a double end : we can in this way express our friendship for the United States, and we can equally render a service to professional rosarians by drawing their attention to the need for brief and concise names.

BOOK REVIEWS

THE publication of the fifth edition of the third volume of Schlich's " Manual of Forestry " (Schlich's " Manual of Forestry," Vol. III. Forest Management, including Mensuration and Valuation, by Sir Wm. Schlich, F.R.S. Fifth edition, viii + 383 pages. London, Bradbury, Agnew and Co., 1925. Price 20s.), is a sure indication of the merits of the book, and of the importance of the subjects treated, which comprise Mensuration, Valuation and Management. The text has been in a great measure rewritten, and a considerable amount of new matter has been added. The production of the new edition has been no easy task, and Sir William Schlich must be congratulated on his crowning effort of a long life spent, first in the interests of Indian and later of British forestry. The book is a wonderful achievement for a man of eighty-five years of age.

This particular volume of the " Manual of Forestry " has been often considered too difficult for the ordinary landowner or the working forester to grasp and master ; and no doubt the array of numerous formulæ, graphs and tables, have a deterrent look. Nevertheless, the mathematics involved are not of a very advanced character, and the technical terms employed are readily understood. All arts and trades which involve money value, compound interest, exact measures of products, and the like, do necessitate the use of applied mathematics, and the owner of woodlands and the skilled forester cannot ignore this study, except at the risk of financial loss. It must be remembered that an accurate knowledge of the volume of growing timber, its location, and its rate of production, is essential if a forest property is to be managed by ordinary business methods.

The first part of the book, Forest Mensuration, deals with the determination (to a fair degree of accuracy), of the dimensions, volume and rate of growth of single trees, and of woods and sample plots. Various methods of measuring standing and felled timber are described, and illustrations are given of the instruments that are used in this work. Particularly noteworthy is the section treating of the measurement of growing woods. The latest methods are included, such as the volume-curve method, Block's method of forming groups, the form-quotient or Swedish method, and the method used by the British Forestry Commissioners in connection with permanent sample plots. The preparation of yield tables for different trees is carefully explained. Yield tables have, up to the present, been compiled only for the more important species, and give the volume and number of trees per acre, their height and diameter, thinnings, rate of growth, etc., for different ages from youth to maturity, and for different classes of soil. Formerly we were dependent on German yield tables, but the Forestry Commission has begun to study the conditions of tree growth in the climate of these islands, and has already published yield tables for European larch, Scots pine and European spruce, which are based on measurements taken in a large number of adequately stocked sample plots situated all over Great Britain. Yield tables are necessary in all countries, where systematic management of forests is aimed at.

Part II is devoted to Forest Valuation, and is mainly actuarial, showing how the financial results of forestry may be determined. This part has been entirely re-written, and is up-to-date, the examples being taken from British money tables. These are calculated on the basis of the measurements recorded in Forestry Commission Bulletin No. 3.

The third part of the volume deals with increment, rotation, age classes, normal stock and normal yield. These are important subjects to study in the case of a large forest property, where the main object is economic and what is known as " sustained yield," is desirable. By this term is meant that the amount of timber felled each year is equal or approximately equal. This ensures a constant market, and secures to the owner a steady annual income. It affords constant employment year after year to a regular number of workmen, who can be properly instructed. The importance of these chapters in the book to officers administrating state-owned forests, is evident.

The fourth part of the book is concerned with the preparation of forest working plans, which are essential for the proper management of all woodland estates and large forest properties. This part has been greatly improved and enlarged in the present edition. The volume concludes with six appendices, of which three are tables of round and quarter-girth measurements and of compound interest. Appendix IV gives abstracts from British and Continental yield tables. Appendices V and VI are examples of two working plans. —A. HENRY.

ONE need not be deeply versed in mycology to enjoy the story of those strange plants, the fungi, as presented in this attractive volume, " The Romance of the Fungus World," by R. T. and F. W. Rolfe (Chapman and Hall, 12s. 6d.), for the " fungi " of which the authors have most to say are just those common, yet curious, vegetables, of various forms and dyes, which, in meadow and in woodland, spring up in a night and which from childhood days one has grown accustomed to call by certain names, conscious often, if not always, of a passing shiver or a loathsome feeling. Think of toadstool or puddockstool ; and has not " fungus " itself an evil smell about it ? Whether it be the philology of these names and others, such as morel, mushroom and truffle, or the gastronomic value of the articles they represent, of which we wish to learn, we shall find something to help us within the pages of the book. In a few chapters which make interesting and pleasant reading, dealing with what may be called fungus-lore, the authors have brought together many literary and historical references from sources that are seldom quoted in the general run of mycological works. From early superstitions concerning " fairy rings " and " witches' brooms," we are introduced to the more modern but equally mythical mushrooms of the moon, monstrous coralline growths, possessing strange properties.

Fascinating as the mushroom of romance may be, it must give place to the mushroom in reality, and from the fungus of legend the authors pass to consider the fungus as it actually exists, its structure, mode of life and its place in the realm of nature ; and to these aspects of their theme they devote the greater part of the volume. The characteristic family features of the larger British fungi are clearly and concisely given, together with appropriate text-figures. The physiology of the group, so different from ordinary green plants, is also discussed, since it gives the fungi a very special place in the general economy of things. As disease producers, both in plants and animals, not excluding man himself, they are responsible for much damage ; nor do they leave alone the works of man. Yet the fungi are not without their uses. In medicine and in industry they play their part, while as food plants they deserve more attention than they have received, at least in this country. In France, Germany, Italy and Japan, as well as in other countries, the mushroom trade is officially recognised, and in certain districts it amounts to a considerable and profitable industry.

CURRENT WORK in the HERBACEOUS BORDER

THE advent of June usually shows the early summer border at its best, and the climatic conditions this year and last have been such that a particularly good display may be found in most gardens. The success of these borders should by no means encourage the gardener to rest on his laurels, however, with regard to the main display which will come in July, August and September.

These later borders should be kept scrupulously clear of weeds, for almost all herbaceous plants are gross feeders, and

THE BROAD DRIFT OF BLOOM IN A SUMMER BORDER.

the best made of borders will scarcely find adequate nourishment for plants and weeds. Small grass weeds, uprooted last month and left to shrivel on the surface, will be found to have formed fresh roots, and unless these weeds are promptly dealt with several barrow loads will have to be removed where one or two emptyings of a fair sized trug should suffice. Do not look at the consequences of neglect solely from the point of view of wasted labour, on the " stitch in time " principle, but stop to consider the plant food of which the neglected border has been robbed. Good gardeners, working on light and hungry soils and not content with the natural garniture of weeds usually to be found in late autumn in the kitchen garden, sow a catch-crop to use up, as far as possible, the feeding elements ready for immediate digestion, so that, the leaching rains of winter past, these available plant foods may be restored to the ground simply by digging in the catch-crop. The value of the process consists entirely in the restoration of the nitrates and other essential soil ingredients by burying the crop of otherwise uneconomic material; judge then of the loss which is likely to accrue to a permanent border if an equal or greater bulk of vegetation is removed altogether.

Beyond early and careful weeding, current work in the border will consist of staking, hoeing, feeding, the combating of insect and fungoid pests, and, if necessary, mulching. Staking, when it becomes due, is urgent. Very few people like to see a forest of stakes towering above the plants (some dahlia enthusiasts seem to be an exception to the rule !), but a delphinium, for instance, once it starts to " run " to flower, may extend anything from 1ft. to 2ft. in a single week. The gardener with the seeing eye will know just when this rapid extension is due, and will place his stakes in position at the appropriate moment. In the case of a reasonably sheltered border, stout bamboo canes, 4ft. tall, will be ample to stay even really well grown delphiniums, but in exposed situations, strong hardwood stakes, at least 6ft. tall, will be called for. The hollyhock, as usually grown, requires similar support, while many of the taller mulleins (verbascum), are self-supporting, unless, indeed, the plants are spindly through over-thick planting. That these stakes should be so inserted that they will be as inconspicuous as possible when growth is completed, goes without saying; and this, in practice, usually means placing the stake *behind* the plant to be secured, but where damage, when it occurs, always follows wind from some particular quarter, the stakes should be placed to windward, and pains be taken to conceal them, as growth takes place, by training shoots to mask them.

The staking of plants of slighter growth requires a little more subtlety of thought than many otherwise good gardeners appear to possess. Delphiniums of the Belladonna set look truly pitiable when carefully trained up formal stakes, and such kinds as Erigeron speciosum, though stouter in growth, look little better when forced to grow erect. The erigeron is an untidy plant and any attempt to make it imitate the smug " maximum daisies " is foredoomed to failure. Let us, rather, grow it in bold drifts, using short, rather stout hazel or maple brash partially to support the plants farthest from the eye, leaving those towards the front of the border to tumble at will over pinks, alyssum or other spring flowers which may form a front edging. Some plants, such as the single and double forms of Gypsophila paniculata, may be sustained satisfactorily on the " bundling " principle—that is, by the use of one stick towards the centre of the plant and encompassing strings at intervals, but care must be taken not to secure the growths for too great a distance from the ground. In the case of phloxes, which have had the growths suitably thinned, a fairly slender stake to each spike is a not unreasonable proposition, and Michaelmas daisies, grown on the now favoured single-stem principle, will receive the same treatment. As a general rule, however, the staking of plants in the front half of the border may be most satisfactorily arranged by the free use of feathered brash of the kind we commonly use for annual climbers, such as the sweet pea. The light tips of these feathered stakes will come in useful, equally with the stouter bases, and very little raffia should be required. Where tying is necessary, the material used should be soft in texture and be twisted several times, so that stems may expand without being constricted or even severed by the tie. This is particularly necessary with stout-growing kinds, such as the delphinium.

The day is not far distant when the use of the hoe in the herbaceous border will become impracticable for this season; until that day arrives, use this essential tool very freely, striving always to get a fine surface tilth which, while aerating the soil, will help, later on, to retain soil moisture. Should a dry spell threaten, a mulch of more than half-decayed manure, or even of rough leaf-mould or lawn clippings will prove beneficial,

Digitized by Google

and in any case, its use can do no harm. The delphinium, in particular, appreciates frequent dressings of "fat" material, from which the nourishment will percolate to the roots.

A border thoroughly well made within the last three years should produce a wealth of blossom without summer feeding, but the grosser kinds, particularly phloxes and delphiniums, repay attention, and occasional doses of weak solutions of sheep or hen manure, or of soot water, help very considerably. These should, if possible, be applied after soaking rain, otherwise a preliminary soaking with rain-water, or its equivalent, is necessary.

The sprayer will be in fairly constant use now in the rose garden and any aphides on herbaceous plants should present little difficulty. The fortnightly use of Burgundy mixture or a special fungicide, is necessary in many districts if hollyhocks are to be successful, and Burgundy mixture is also reasonably effective against mildew on the delphinium. The only sure preventive of this, however, is to shun, or, if necessary, discard varieties subject to this plague. Diseased growths of most herbaceous plants should be removed forthwith, before the mischief can spread. These should be burned so that there is no chance of infection to other plants. R. V. G. W.

STAR AND MIGNON DAHLIAS

AMONG DECORATIVE FLOWERS, THE DAHLIAS, MORE ESPECIALLY THE STAR AND MIGNON FORMS, STAND OUT AS PRE-EMINENT FOR USE IN BEDS AND BORDERS. WITH THEIR LONG PERIOD OF BLOOMING AND BRIGHT WARM COLOURINGS THEY ARE INVALUABLE.

DURING the last few years great progress has been made in the cultivation of dahlias. All the older varieties have been improved upon and new varieties have made their appearance. Among the latter are two forms of outstanding merit in the progress of horticulture, the star and mignon dahlias. Their peculiarities are quite distinct, inasmuch as the star dahlias attain a height of 4ft. generally and the mignon dahlias only 18ins., but they both share the same distinction of being something different from other kinds.

The star dahlia was raised and first introduced by Messrs. J. Cheal and Sons, Limited, and the first variety was known as Crawley Star. The flower is a fine clear pink. This was the forerunner of a collection which has rapidly become popular, and is well worth growing in every garden. They are very free-flowering and carry their blooms on long, stiff stems, which make them very useful as cut flowers for house decoration.

The star dahlias are more self-supporting than the large-flowered varieties. Three 4ft. canes are adequate support in the most exposed places, and one cane in the centre in sheltered positions. They have also another asset, they do not encourage earwigs, which have always been a drawback in the good cultivation of the older varieties. The varieties are now too numerous to be detailed. Each variety has been chosen for its distinct colouring and shape of flower, also for the good form and habit of the plant. The selection that now exists affords a wide choice for every taste.

Some of the varieties of outstanding merit are Haslemere Star, introduced in 1924, which has very clear rose pink flowers borne on long, stiff stems. This variety has been recommended for trial at Wisley.

Horsham Star is another 1924 introduction with coppery rose-coloured flowers turning to mauve in the centre, which produces a very pleasant effect.

STAR DAHLIAS AT MUNSTEAD WOOD.

Some of the earlier varieties are Bronze Star, which is true to its name, the flowers are a rich bronze, turning darker towards the centre; Cuckfield Star, yellow with a pleasing tint of pink; Primrose Star, a fine clear primrose yellow, the flowers produced in great profusion; Southern Star produces a charming colour scheme of crimson, apricot and purple; White Star, a lovely pure white, the petals conspicuously shown off by orange-coloured stamens; Yellow Star, a delightful yellow, which has become popular owing to its clear colouring.

The mignon dahlias are absolutely a class on their own, and, as their name signifies, their dwarf nature, their usefulness as bedding plants or for the edging of borders is unique. They are not fastidious as to soil, and do not require any stakes for support. The most important point in their culture is to keep the old flower-stalks picked off. Failing this, they soon cease to flower. There is a wide range of colour among the numerous varieties, and it is difficult to choose between them. Some of the favourites are Albion, pure white; Benbow, crimson; the well known Coltness Gem, crimson-scarlet; Daphne, maroon; Dazzler, a fine orange-scarlet; Janet, bright orange; Kathleen, a deep apricot; Louise, delicate primrose, very effective and very popular.

The star and mignon dahlias require the same treatment as other varieties. They should be planted out about the first week in June. A little soot or lime put round each plant as a protection against slugs is advisable, also liberal watering and syringing after a hot day will help the plants during the growing season. On light soils mulching will be beneficial in dry weather. The star dahlias should be planted from 3ft. to 4ft. apart and the mignons from 15ins. to 18ins. Neither of these varieties require thinning or pinching, and both provide an excellent splash of colour in the later months of the year. R. C. J.

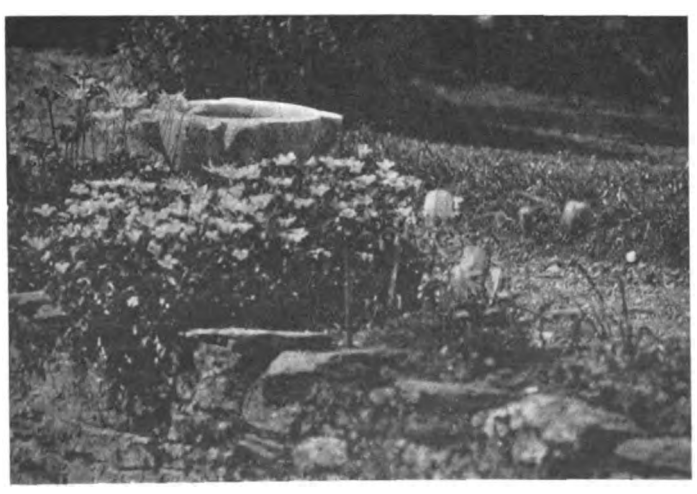
MY ROCK WALL

A GARDENER S PLAYTHING

MOST gardeners have some little corner of the garden which they regard rather in the light of a toy. For some it is a little rock garden, for others a small pond. The object of such a corner is to have a place on which to waste a lot of time and lavish any amount of care. The result is usually something very fascinating. Each plant takes on a personality of its own and is on very intimate terms with the gardener, who must, of course, be an amateur, no professional gardener could possibly afford the time involved to cherish and fuss all the little plants.

My little corner is a rock wall. It is only some 15ft. long and rather more than a foot wide. It runs along a little path by the side of the lawn and is only raised a few inches above the path on this side, but on the other there is a drop of from 1½ft. to some 3ft. to the drive, which slopes rather steeply downwards. My wall is made of flat country stone roughly cemented together with mortar. Along the top of the wall a shallow trench but a few inches deep is left, edged with stone and filled with good sifted soil. The drainage is thus perfect, and most of the common rock plants revel in their quarters and flourish amazingly. I have nothing uncommon or rare on my wall, and yet there is always something of interest on it. It is my endeavour to keep it gay with flowers from end to end from early spring to latest autumn. "How is this possible in so restricted a space?" you will ask. The method is very simple. Certain plants which dislike being moved have to remain on my wall all the year round, and do their best to beautify it with their graceful foliage or neat habit of growth. Others flower and are then carefully removed, and something else is popped into their place. It is really a most amusing game. The earliest flowers of all are those on the neat little cushions of Saxifraga apiculata, which have been a continual joy to me throughout the winter. The buds appear early in February, and by the end of the month the small green mounds look quite gay studded with their yellow flowers. Following closely on their heels a few chionodoxas and scillas open their little blue bells. Then a common little pink mossy saxifrage ventures out. But in the meantime the soil has been stirring at the other end of the wall and the little dark red leaves of the Apennine anemone can be observed pushing through with the buds pointing downwards and almost indistinguishable from them. Before you can turn round these have grown up into a bold clump with a show of lovely blue flowers. This encourages Saxifraga Wallacei to come into bloom, contrasting well with the blue of the anemone, which, alas! is already on the wane. This brings us to the first of May and the fritillaries have opened their snaky heads. Saxifraga apiculata has now been removed to summer quarters, and a charming little pink daisy, Dresden China, in full bloom, has filled the vacant niche on my wall. For weeks the buds of Gentiana acaulis have been slowly forming, protected by a little penthouse made from a couple of old half-plates, for this plant dislikes the continual rains of our English winters. It is a long time to wait for the first streak of colour to develop into the wonderful blue cups, reminding me of the Alps, where it grows so luxuriantly on apparently nothing but stones.



THE WALL IN EARLY SPRING, WITH SAXIFRAGA WALLACEI AND THE APENNINE ANEMONE.

SEMPERVIVUMS NESTLING AMONG THE CRAGS IN THE ANNEXE.

Next come two or three saxifrages of the London pride group, but not the London pride itself, as this is far too vigorous for my wall. These are the dainty little plants cuneifolia, primuloides and umbrosa minor. Quite common things, but each one with its own charm and grace. So many rock gardeners scorn to grow such common things, but I never could understand why. A lovely great hummock of thrift is now thrusting out its dark pink buds. No doubt its tap root has gone right down through the stones of my wall. After the saxifrages have had their day the campanula family carries on towards midsummer, when those lovers of the sun, the rock roses, give me a brave splash of colour. Only single ones are allowed on my wall, rather unruly members, they are inclined to want all the room for themselves, ousting the other plants growing near them. They have to be placed near a mossy mound of Saxifraga serratifolia, which is quite capable of looking after itself. They are useful, however, for their foliage remains throughout the winter to clothe the wall.

The year is brought to a close by the stonecrops, of which several fill in odd corners. Sedum elegans with its nice reddish foliage is a particular favourite of mine. It looks well all the year round and best when it throws up its yellow flowers, which contrast so well with the leaves. It has a very charming way of popping up between the stones where you least expect to see it. In the gap left by Anemone apennina, when this has died away, a seedling viola of some choice colour will go on flowering into the late autumn.

My wall has a continuation, a sort of annexe, on which the houseleeks in great variety fill the spaces between the granite and glistening quartz peaks. When grown like this they provide one with a source of interest which is never ending. Here are to be found those with the silky white threads spread from point to point of the little rosettes like a spider's web. It is a matter of common observation that this web is much more pronounced on the new growth in early summer. It is produced by the plant as a shield to ward off the intense heat of the alpine sun which might otherwise damage the tender young leaves. Here are also to be found quite sturdy rosettes of a glaucous green with pretty reddish brown tips, medium-sized rosettes, with the leaves beautifully curved outwards and those with the leaves tightly pressed together to form a compact ball—in fact, forms of almost infinite variety and colour. It is difficult to credit that they are all cousins of our common houseleek.

One of these sempervivums is sufficiently interesting to call for special mention. This usually goes by the name of "hen and chickens," from its habit of throwing off minute rotund rosettes which roll away from the parent plant to form

Digitized by Google

the nucleus of a new cluster elsewhere, the future generation looking after itself in a most independent manner. In such quarters as my wall affords these plants are only too ready to throw up flower-spikes terminating in a cluster of dull pinkish stars, which are all very similar and to me uninteresting. They are produced, however, in rather a fascinating manner. One of the rosettes of a group slowly lengthens out until the stem is formed, the leaves of the rosette going to clothe this stem. Buds then make their appearance at the top, which duly open and then die away. But now comes the tragedy. Where the flower was is now a dead rosette. When this is removed a nasty gap is left in the neat cluster, requiring time to heal the wound.

Though my walls are made of flat country stone, just because it happened to be there, there is no necessity to use stone. Bricks would do just as well, provided they were not too well put together or too elegant-looking. Of course, they would not have to be pointed. Old bricks would really be the best to use for this purpose. The old red colour might be even more effective than my grey stone. EDWARD CAHEN.

COTTAGE GARDENS

IN going about the country one often comes in contact with cottage gardens where many old-time flowering plants and shrubs find a home, and which convey the idea of their having been long established. The general arrangements of these gardens are such as to leave no shadow of doubt that they were not designed of late years, but were the outcome of work of earlier days; indeed, the impression which remains in the memory is that, apparently, the design and formation of the gardens which satisfied and pleased one generation was accepted by the next without any radical change being effected. You can scarcely fail to recognise such places when once you see them, as there is about them an old-time atmosphere—a sense of repose and quiet—that impels you to pause and admire, because they are something different from what is found in modern gardens. Some of these gardens may yet be met with, and not infrequently they are found in outlying villages, off the beaten track, as in the West Country under the shadow of the Cotswold or Mendip Hills. My mind reverts to one I visited years ago. It was partly surrounded by a yew hedge, the density of which indicated its antiquity, but good sense had been shown in that it was not too high to obscure vision of the road. The house itself, a stone structure, stood some distance back, so that most of the garden was visible from the windows. Stone, evidently of local origin, had been freely used in the formation of paths, for the edging of walks, and in building low walls. The great artist, Time, had weathered the stones in varying tints of amber and brown, and had also left its mark on the once grey tiles on the roof of the house. In a corner of the garden was a well, the only source of water supply, which had never been known to fail, built up about a yard above ground level, and lined with the same kind of hard stone. Covering the approach to the well, and visible for quite a long way down, polypodium ferns grew in profusion between the niches. Here and there the dense yew hedge had been cut in, leaving recesses for stout oak seats—nests for rest on summer days. One was not surprised to find box employed for edging certain beds on the lawn and some of the borders, but its regularity demonstrated that the shears had been used periodically, so much, indeed, that it was neat to a fault. My visit was in late spring, when laburnums were commencing to hang their trails of gold, and before the last of the flowering currants had disappeared. The borders attracted me greatly, as in them were clumps of crown imperials, of orange globe trolliuses and, what in these days one does not often see, Fair Maids of France (Ranunculus aconitifolius). Fading foliage of crocuses and snowdrops indicated where, earlier on, in company with chionodoxas and winter aconites, the first days of the year had been ushered in with beauty. In the self-same borders, the older type of Columbine alpina grew side by side with tree and herbaceous peonies; the thick coppery green shoots and leaves of the latter plainly spoke of roots having been undisturbed for years. Of lilies there were few, notably groups of white Madonna, whose peerless blossoms at the time of their opening were enshrined by a background of dark fir. But there were other oft-called lilies in those borders that were at home—day lilies, for instance, like the hemerocallises, Peruvian lilies in alstrœmerias, and those brilliant flaming spikes of autumnal days, torch lilies—the tritomas—which added glamour to the garden in the time of fast-falling leaves.

SWEET LAVENDER IN AN OLD-FASHIONED COTTAGE SETTING.

I noted clumps of delphiniums, that were called by the owner of the garden by their older name, larkspurs, and dielytras and campanulas with pinks and rockets were given places of honour.

Here were hedges of sweet briar, bushes of lavender and rosemary, and thymes and other herbs in variety. Some of the bushes were of a size as to leave no doubt of their having reached a good age, and, to account for this, one could not help thinking that not only the soil, but the clear, unvitiated atmosphere of the countryside explained the vigorous growth. Of creeping and climbing plants there was a limited number. The garden arch, with rambler roses, was not to be seen, but round the doorway and over the walls of the house not occupied by branches of Victoria plums, white and yellow jasmines and a wistaria clambered. The porch itself was clothed with honeysuckle. It was a garden that tempted one to linger, because among the plants and flowers found growing within its enclosure one became conscious of a subtle charm—nay, it was even more than this, for it was typical of an old and fast disappearing style of an English garden, about which, as you reluctantly left it, you could not help saying, "How very nice it all is." W. LINDERS LEA.

THE CANADIAN KEW

BY GEORGE SIMPSON.

CANADA abroad, especially in Great Britain, is thought of as a land of illimitable spaces and fertile plains, "the granary of the world," and not particularly as a land of fruit and flowers. Yet Canada, by reason of the wide range of its climatic and atmospheric conditions, is singularly adapted to the cultivation of a great variety of fruiting and flowering plants. Commercial horticulture has established itself upon a firm basis in such widely separated regions as the Annopolis Valley of Nova Scotia, the Niagara district of Ontario and the Okanagan country in British Columbia, not to mention numerous other localities where fruit-growing is carried on profitably.

Thanks to the exertions of voluntary societies, ornamental gardening is making rapid advances in urban and rural Canada, especially in the provinces of Ontario and British Columbia. The proportions to which this steadily growing movement has attained will be appreciated when it is stated that the membership of the Ontario Horticultural Association, a federation of local horticultural societies, has reached a total of almost sixty thousand adult amateur gardeners—this in one province only. Governments, provincial and federal, have taken note of the movement and are supporting it, not only by direct money grants, but by the maintenance of botanical and horticultural gardens and of horticultural teaching in universities, colleges and schools.

Chief among the agencies for the dissemination of horticultural knowledge is the Horticultural Division of the Dominion Experimental Farms, and it is at the Central Experimental Farm at Ottawa that we have what we sometimes call our Canadian Kew. Research and experimentation in subjects having commercial applications are carried on by staffs of experts, but our concern here is with decorative gardening as it appeals to the average private gardener seeking to improve his home surroundings, to indulge a hobby or pursue a speciality. In the academic sense gardening is not taught, but its practicable phases are illustrated in the extensive plantings within the horticultural limits as distinguished from the purely agricultural areas of the farm and also in the well stocked arboretum. The general gardener will be instructed by examples of well arranged perennial borders containing the principal varieties of hardy herbaceous plants suitable to Eastern Canada; summer-flowering annuals in effective groupings and especially by the great variety of hardy flowering shrubs and trees that thrive under the somewhat trying conditions encountered in the Ottawa Valley.

The specialist will find available for study and comparison most complete collections of Iris germanica and hybrid herbaceous peonies. These outstanding plants are especially adapted to Canadian conditions; they are largely planted in private gardens, a society has recently been organised to proclaim their merits and promote their cultivation, and they are honoured, like the rose, by being made the subjects of special shows.

The rose, too—principally the hybrid tea and Pernetiana—has its devotees, and at the Farm will be found almost everything worth while and some things not at all worth while, because the Farm takes the risk of trying out unknown varieties, thus saving the individual that trouble and expense. Roses originated by the principal growers in England and Ireland are planted in large numbers and it is astonishing how quickly the great majority adjust themselves to the changed conditions of their new home, proving that the rose is not only a hardy, but an exceedingly adaptable plant. Even the teas, with careful winter protection, come through, but the casualties in this class are great. The Farm is looked to for information not only in regard to the growing of roses, but also in regard to methods of winter protection, because it is only the rugosas and other hardy species that will survive the winter without covering. No attempt is made to prevent the rose bushes freezing, but the aim is to keep them dry and to restrain growth in the spring until weather conditions are such that it may proceed without interruption. All feasible methods of protection are experimented with and the results published for the information of rose growers. The two plans that have proved most successful are (1) laying the rose flat, covering with dry leaves and placing over all a roof made of two boards nailed or hinged to shed water, or (2) covering the recumbent bushes with dry leaves, and over this placing evergreen boughs to check winds and hold the snow; because, after all, snow is nature's own protecting material and is effective provided it comes in quantity before a hard frost and remains until settled conditions return in spring. But the snowfall may not come until after severe freezing weather in December and following its disappearance in March a cold spell may do irreparable damage to the new growth. Hence the necessity for artificial protection.

A BORDER OF SUMMER FLOWERING ANNUALS.

THE IRIS WALK AT THE EXPERIMENTAL FARM.

The cult of the gladiolus—perfectly suited to Canadian summer conditions—is hard pressed in the effort to keep pace with the rapid multiplication of varieties. Thousands are grown at the Farm under conditions that facilitate comparison; and, that the information derived from these plantings may be distributed as far afield as possible, educational exhibits of cut blooms are staged at the principal agricultural, horticultural and industrial shows.

Does the home gardener contemplate the planting of a hedge? Many specimen hedges, deciduous and evergreen, are placed side by side, clipped and tended, ready for inspection, each disclosing some point of superiority or suggesting its suitability for a special use or position.

Digitized by Google

A good deal of original work is being done in plant hybridisation, and some outstanding results have been obtained, notably in the production of the roses Mary Arnott and Agnes, the chrysanthemum J. R. Booth, an enormous yellow bloom, and a dozen or more greatly improved varieties of geraniums. The extensive conservatories stage a chrysanthemum show in November that attracts visitors in thousands and does much to acquaint the non-gardening public with the horticultural resources of the Farm.

To many the most interesting part of the Farm is the arboretum, where are collected the principal native and exotic trees and shrubs hardy in Eastern Canada. These are the survivors which have stood the test and can be recommended to Canadian planters with assurance; but, in the almost forty years of the Farm's existence, everything that gave promise of success has been tried—many shrubs and climbers that are accepted as commonplace in the gardens of England—and there have been casualties without number. Failures and successes have been noted and the printed record is at once a warning and an encouragement, because it shows what to plant and what to avoid. In the arboretum there is a perennial border half a mile long containing a fairly complete collection of indigenous and foreign hardy plants, and including less known dwarf perennials suitable for the edging and the rock garden. Many of these dwarfs are grown from seed obtained from abroad, because the Botanical Division which has charge of the arboretum maintains a correspondence and seed exchange with the great botanic gardens of the world.

Obviously, results obtained at Ottawa, where winter temperatures drop—very occasionally—to 20° below zero or lower and where summer temperatures rise—also very occasionally—to above 90°, would have little or no meaning for the gardener at Victoria, British Columbia, where conditions similar to those in the South of England prevail and where the early spring bulbs come into bloom in February, while the gardens in Eastern Canada slumber on under their protecting mantle of snow. Nor would these results be applicable to the severe conditions of the prairie regions, where winter temperatures are sometimes low and the snow covering light. Because of these climatic variations some thirty branch farms, stations and sub-stations, have been established in different parts of the country and at nearly all of them horticultural work is carried on and demonstration plantings are maintained. An interesting detail in connection with this local and specialised experimentation is the work that has been done at Sidney, British Columbia, to demonstrate the practicability of bulb production on a commercial scale on the Pacific Coast and particularly on Vancouver Island. Darwin tulip bulbs of high quality have been grown showing that the question is economic rather than cultural. The mildness of the climate has made it possible for the Sidney farm to draw upon the world for its unique collection of flowering plants and shrubs, including many semi-tropical varieties that could not survive in other parts of the country. Rhododendrons and ericaceous plants generally do well here and roses yield their blooms in continuous succession from May to December. On Vancouver Island the English gardener is perfectly at home.

A FINE DISPLAY OF BLOOM IN THE CHRYSANTHEMUM HOUSE IN NOVEMBER.

GARDENS OF HEALING.—III

THE Health Garden can be beautiful as well as useful and interesting, for many of our flower favourites have an honoured place among the plants endowed with beneficent qualities. In fact, something of everything can be included in the medical garden. If a field were set apart for the purpose, trees and vegetables with healing properties, as well as herbs, fruits, flowers and some plants which we now designate as weeds could be included.

LILIUM CANDIDUM.

Much care is given to the cultivation of the Madonna lily on the Continent for its beauty and also for its medicinal properties. Nothing is perfect here below, and the Madonna lily has its faults. Its scent, alluring and delicious in the garden, is harmful in a room and gives rise to severe headaches and even syncope. The petals should be handled lightly, collected as soon as the flowers expand, and dried slowly *in the dark*. They are then steeped in brandy for a week or two. This decoction is used to heal cuts and bruises and to stop excessive bleeding of the former. The bulbs are dug up in the late autumn and stored in sand in a dry cellar. They are mixed with lard and boiled in milk, or cooked on ashes and applied as hot poultices for chest complaints and to assuage all violent pains.

PRIMULA VULGARIS.

Stuffy colds in the head are quickly relieved by primrose roots gathered during the winter, dried and reduced to powder and then mixed with honey or boiled in wine. Chronic headaches may be treated with the same medicine.

Infusions are made both with primrose leaves and flowers. The former allays feverishness and the latter is used extensively in France for biliousness, indigestion and nervous disorders, such as St. Vitus' dance, epilepsy and palpitations.

Boiled primrose leaves applied when very hot speedily relieve rheumatism.

CONVALLARIA MAJALIS.

The rhizome of the lily of the valley is used in pharmacy as an emetic, and an infusion of the flowers (1oz. to a pint of water) is a valuable lotion for inflamed eyes or for earache. A snuff made from the powdered flowers relieves headaches.

VIOLA ODORATA.

The sweet-scented violet is one of the most wonderful of plant healers, and seems to be coming into its own again even in England, where we so greatly ignore the virtues of our native plants. It is amazing that its properties are known only to the few.

Some eminent medical men do not deny that an infusion of violet leaves is a great aid in lessening the pain of that distressing malady, cancer. Cases have been known where, in its early stages, that disease has been arrested by applications of violet leaves. In Ireland everyone knows this, and violet leaves are universally used for this complaint. Quite recently I have been told of undoubted benefit being derived from this simple remedy in a case where the disease was far advanced. On the Continent, too, such poultices are used, not only in cancer cases but to cure sores, bruises and inflammation.

An infusion made from violet flowers is a soothing drink. It is a remedy for colds, coughs and bronchitis, and stays irritation in rash diseases. This is in use in many country places in Britain.

In Arabia and Egypt, crystallised violets are served with coffee as an aid to digestion.

One of the choicest wines of the ancient Romans was made from violet petals, and both they and the Greeks wound wreaths of violet leaves round their heads as a cure for severe headaches.

VICTORIA SLADE.

Digitized by Google

IRISES AT VINCENT SQUARE

THE beautiful collections of irises were the predominating feature at the fortnightly meeting of the Royal Horticultural Society at Vincent Square Hall on June 9th and 10th last. Peonies were noted as the main item in the syllabus, but these were conspicuous by their almost total absence save for a few exhibits. It is certainly strange why this flower is not grown more in this country than it is. In America, widespread interest is taken in its cultivation; horticultural friends over there are doing their utmost to kindle our enthusiasm, but apparently to no avail. The Show was a representative one and presented a magnificent blaze of colour, such as only early summer and the glorious weather of the preceding days can produce.

Messrs. Kelway's name is well known throughout the horticultural world, and more especially in connection with peonies. They fully lived up to their high reputation by the exhibit which they put up. The large blooms of almost all shades provided a vivid splash of colour. Among the single-flowered varieties we noted R. W. Marsh, with petals of a fine colour of bright chocolate-crimson; Victor Hugo, with fair-sized handsome blooms well carried on good stems. The spreading petals were of a rich deep blood crimson shade. While in the choice double-flowered forms we found Lady Stradbroke, with huge heads composed of soft pink petals; Kelway's Rosemary, of a soft rosy pink shade with a tuft of lighter petals in the centre and with a haunting fragrance. This is a most attractive variety. Another sweetly scented variety was Helen Glover, whose many rather short petals of a light rose, almost flesh-coloured, shade give the flower a characteristic appearance.

Another fine exhibit was that staged by Mr. K. Gifford, Hornchurch. This consisted of sprays of Pæonia albiflora grandiflora in vases. The blooms were large and handsome, fully 6ins. across. The appearance of the flowers is enhanced by the large cluster of golden stamens in the centre of each, which stand out like a miniature pin-cushion. It presented a most striking appearance when seen in the mass.

Mr. J. C. Allgrove was also showing a few species and varieties, such as Pæonia Delavayii and Veitchii, both characterised by their dissected foliage and small yet nevertheless handsome flowers. Pæonia The Bride was also shown and attracted considerable attention. They were shown off to advantage by the huge spikes of Eremurus robustus Magnificent, which acted as a fine background to Mr. Allgrove's stand.

Irises formed the chief exhibits. Magnificent collections were shown by a number of firms, and the tall spikes of bloom in blue, purple and yellows greatly added to the floral display. From these groups the garden value of the iris could be well appreciated. Some of the newer varieties, especially those not yet named, were singularly beautiful. The texture of the petals, the general shape and form of the flowers, as well as the colouring, was remarkable compared with the garden iris of twenty years ago.

Messrs. Wallace had an excellent exhibit of some of the finest varieties grown in their iris fields at Tunbridge Wells. Souvenir de Mme. Gaudichau, with large violet standards and velvety purple falls, was one of the most striking of the neglecta section. Lent A. Williamson was a variety of great size, with flowers formed of soft lavender standards and velvety purple falls, on which bright golden beards made a pleasant contrast. Pioneer, one of the best reddish purple irises raised recently, had a bright golden beard on the glowing purple falls, and is a variety of vigorous growth. Queen Caterina, a pale lavender-violet self; Shekinah, a lemon-yellow; and the beautiful variety, Ambassadeur, with its reddish-violet standards and velvety brown falls; Gold Crest, Sindjkhat and Leonato, are only a few of the handsome irises exhibited by Messrs. Wallace. This firm were also showing Prospero, Dora Longden, Gules and Roseway.

Among the collection of irises from the Orpington Nurseries were some interesting varieties—Evadne, a sweetly scented rose-red self, was a well branched variety Harmony, a rich violet blue self; Gabriel, with clear lavender standards, and falls of light violet-blue, deeper at the haft, stood out from among the rest. Asia was a distinct iris, strong in growth, with suffused and reticulated lavender standards and light purple falls heavily reticulated at the haft. Imperator, Red Admiral, Zulu and Tenebrae were much admired; while Quaker Lady and Fro appealed to many.

Many noteworthy varieties were shown by Messrs. G. Bunyard and Co., and considerable care in culture must have been expended to produce such perfect specimens. It was difficult to choose a representative list from such a fine collection, but among them were Monsignor, a tall bearded iris with satiny violet standards and crimson-purple falls; Mdlle. Schwartz; Tristram, with clear white standards and deep rich purple falls heavily veined; and Ed. Michel, a wine-red self. Souvenir de Mme. Gaudichau Ambassadeur, Ann Page, Crusader, Dalila and Mercedes were also shown.

One of the most striking of Mr. Amos Perry's irises was Mrs. H. F. Bowles, a variety introduced by the exhibitor. It is of a colour difficult to describe accurately, the general effect being rich brownish red, formed by soft brown standards overlaid with old gold and brick-red falls. Abenda possessed some beautiful bronzy shades; and Olympus was good both in size and form. Geneva, Dejah, Marjorie Tinley, George Yeld, Mrs. Marion Cran and Mrs. W. Cuthbertson were all well displayed. Among the bearded irises was a group of that beautiful sky blue Siberian iris, Perry's Blue.

Messrs. Lowe and Gibson had some sweetly scented varieties among their meritorious exhibit of irises. Rodney, one of the bluest of the irises; the dainty Camelot, Eldorado, and the handsome flowers of Ed. Michel were conspicuous. Most effective was the variety Crusader, with standards of clear lavender blue and falls of deep violet. Dimity, Azure and the popular Prosper Laugier were also exhibited.

One of the most attractive irises exhibited by Messrs. Waterers was Sweet Lavender, a strong-growing variety of a beautiful rosy mauve shade. The standards were pale lavender, and the widely expanded falls a deep rose-lavender. Cluny, a magnificent variety belonging to the pallida section; Drake, a pale blue; Memory, and White Queen, were all beautiful. The number of blooms on each spike, and the texture of the petals of Messrs. Waterers' irises were exceptionally good.

It was difficult to know where to begin and where to end when making a selection from Messrs. Barr and Sons' splendid exhibit of irises. Groups of flowers of all shades adorned this stand. Some of those belonging to the variegata section were very lovely. Prince of Orange, with rich golden standards and brown falls veined with orange, together with Lorely and Mithras, were typical of this class. Such varieties as Red Cloud, Her Majesty, Stella, Tamerlane and the fragrant Ringdove were seen on this stand.

Mr. George Whitelegg also exhibited irises of all kinds. Empress of India, a fine variety of pallida form; the tall-growing Asia, which, although unusual, is yet effective; Halo, Opera and Nibelungen were a few of those particularly suitable for grouping in the iris garden.

Messrs. Dobbie and Co. of Edinburgh put up a fine exhibit of long-spurred aquileigas in all colours. These were set out in fibre so as to produce the most natural garden effect possible. By such a method of arrangement one can recognise at once the garden value of these beautiful columbines.

One of the best colour effects in the Show was that produced by Mr. H. J. Jones' stand of hydrangeas. Years of cultivation, selection and rejection have had the desired result of producing some of the finest varieties of this flower which we have ever seen. The blending of the colours was excellent—shades of pinks, blues and mauves relieved by dashes of white. A few of the notable varieties on view were Rhinegold, of bushy habit and carrying large trusses of rich pink flowers; Rubis, which may be said to be a new variety, bearing well shaped trusses of bloom tinged with almost a reddish shade; Niedersachen, carrying large trusses of a blue to mauve colour, a most attractive variety; Germaine Mouillere, a pure white variety with glossy foliage. The flowers are fimbriated and are borne in fine large handsome trusses. All these varieties are first-rate plants for interior decoration, and Mr. Jones is to be congratulated on the excellent results which he achieves in the cultivation of this genus of shrubs.

An attractive subject for exhibition purposes was Crassula coccinea minor, staged by Baron Bruno Schröder. It looked remarkably well in the mass, relieved by the greenery of decorative foliage and backed by a few clumps of lilies. This is a robust and shrubby plant which, judging from the specimens shown, reaches a height of about 12–18ins. The leaves are ovate in shape and very closely imbricated, and about 1–1½ins. long. The bright scarlet and slightly fragrant flowers are borne in numerous dense heads, and the plants were very floriferous. They were all well grown, and great credit is reflected on the head-gardener, Mr. E. J. Henderson.

That the season for rhododendrons is not yet over was evidenced by the fine exhibit of hybrids staged by Messrs. Waterer Sons and Crisp. Among many of the fine varieties were to be seen Lady C. Mitford, Bagshot Ruby, Donald Waterer—a new variety, carrying rather flat trusses of rosy pink-edged flowers; Philip Waterer, also a new variety, bearing large shapely trusses of large delicate rose-pink flowers of a good form; and a number of hybrids of R. discolor. It would appear that there is no end to the ever increasing number of hybrid rhododendrons which are entering into cultivation, and it is remarkable how high a standard is reached in the production of these new forms, as was evidenced by this exhibit.

A new arrival in the world of carnations was also to be seen at the Show. This was a new perpetual-flowering variety, named Mrs. Vlasto, exhibited by Mr. J. C. Beck of Henley. It appears to be of a good strong constitution, bearing well shaped blooms of a shade of petunia and white on tall wiry stems. The calyx is firm and of perfect shape, while the blooms have that excellent fragrance reminiscent of an old clove variety, only in a slightly stronger degree.

The lupins exhibited were truly wonderful. The strength and length of the spikes, and the great variety of art shades which are now obtainable, greatly add to the value of this useful border plant. Undoubtedly, one of the most popular lupins of to-day is Downer's Delight, which was shown by nearly every

Digitized by Google

firm exhibiting lupins. In each case it was perfect, both in colour and form. Sunshine, Pink Pearls and Cross Roads are three other favourites.

Mr. G. R. Downer was showing some of the best of his famous lupins, including May Princess, Red Star, Artist, Nublu, and the beautiful white Snowfall. Mr. T. Carlile had some varieties of his own raising among his collection. Lodden Bridesmaid is one of his recent introductions, and is a pale lemon variety with pale lavender keels. 21st Lancers (one of the strongest growing of all lupins and of unusual colour), Milly, Tunic, Apple Blossom, Happiness and Queen of the West were the most conspicuous of this exhibit.

The Maytham Gardens had a special strain of seedling lupins which were vigorous in growth and clear in colour. Maytham Sunrise and Maytham Elegance, a deep pink and a deep blue, were two of the best. Messrs. Harkness and Sons were showing lupins of glorious shades, such as Captivation, Joy, Pink Progression and Annie Myers. An interesting collection of hybrid seedlings in a wide range of colours was shown by Mr. H. Marcham. It illustrated the great value of the newer shades of lupins. Rose Bedder, King of the Blues, Brenda, Mount Everest and Afterthought could be seen among Mr. Maurice Prichard's exhibit. Lupins were also shown by Messrs. Bakers and Rich and Co.

For excellence in arrangement and quality of the flowers, the exhibit of sweet peas by Messrs. R. Bolton and Son was most noticeable. Large bunches of vivid-coloured flowers borne on long stems formed a brilliant array. The number of varieties selected was not great, but those exhibited were some of the best. The novelty of outstanding merit shown by this firm is Gold Crest, a pinkish salmon, a beautiful colour in artificial light. Peggy, Royal Pink, Ivory Picture and Black Bess (one of the darkest of all sweet peas) were other new varieties shown by Messrs. Bolton.

Messrs. Alex Dickson and Sons of "Hawlmark" fame had a varied and good collection of sweet peas. Many of the old varieties as well as several novelties could be seen. A splendid new variety was Crusader, a lovely orange-salmon. Mermaid, a sweet pea raised by this firm, is a soft lavender very similar to Powerscourt. Stella, a large cream with a definite rosy margin; Blue Bird, Purple Perfection and Royal Scot were all striking varieties.

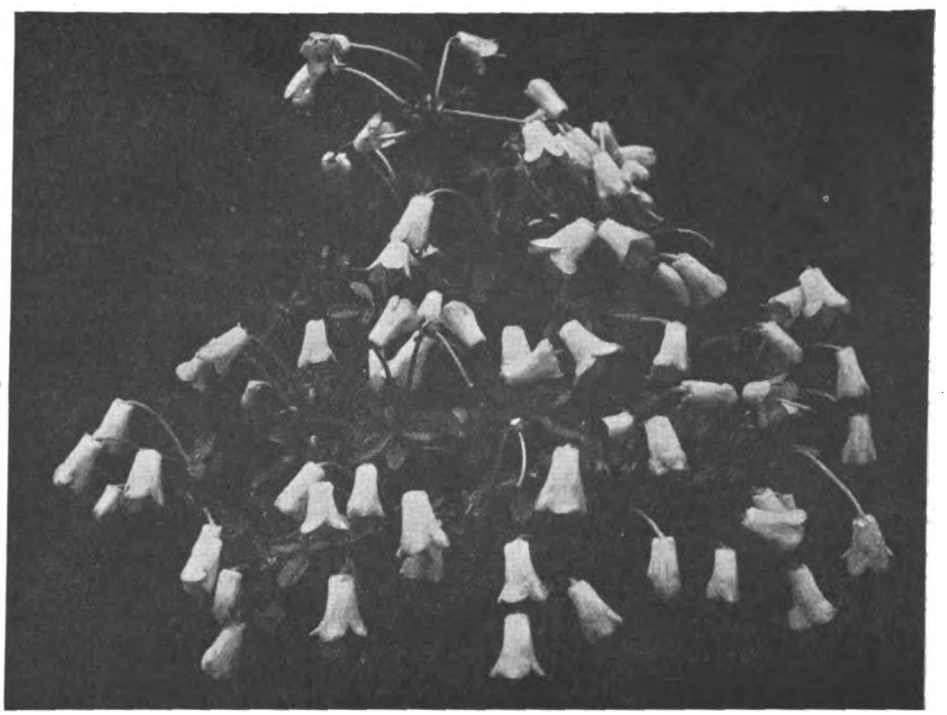
The alpine section seemed to feel that it was the day of the border plants, but there were several very interesting plants in the rather meagre and diminished exhibits.

Messrs. Reuthe showed Conandron ramondioides, the Japanese "mountain tobacco," that promised to be a valuable rock plant, but failed to be sufficiently hardy. It might do well in the warm West Country, and its dark lavender flowers with a golden-brown eye, like a waxy and refined potato blossom, are worth a little trouble.

Messrs. Tucker showed Epilobium macropus, a New Zealander and one of the best of willow herbs for the rock garden, for it is not a pervasive ramper like so many of its family, but makes a neat mat of rather bronzy leaves and covers it with pearly white flowers on dark red stems; Linum collinum, Seedling No. 2, a form that preserves the deep blue which distinguishes L. collinum from L. alpinum, but is more upright and compact than the type; Papaver pyrenaicum, in its orange form, which suffers with the other alpine poppies from being regarded as no more than a miniature Iceland poppy, though they are all high alpines, typical scree plants and quite individual in their grace and brilliance; Aquilegia concolor, which seems to be a neat, dwarf form of A. pyrenaica, carrying its pale lavender flowers rather more upright.

Messrs. Maxwell and Beale showed Dryas Sundermanni, the hybrid between D. octopetala and the yellow D. Drummondii, but their plant had large, pure ivory white flowers instead of the straw yellow ones of the usual form and seemed altogether more attractive; Farrer's Campanula Miranda, a curious plant with flowers that are as nearly grey as any in the garden, and enormous against the tiny leaves; Lithospermum intermedium, that in its own home looks like a tuft of gentian-blue heather and likes a really warm dry spot in this climate; Matthiola fenestralis, a neat little stock in faded purple that looks very well with Onosma tauricum and appreciates the same conditions.

The Hemsley Nurseries showed Cyananthus incana leiocalyx, a curious and beautiful alpine from Yunnan with long prostrate shoots, each carrying a single starry blue flower covered with long silky white hairs faintly tinged with gold; a variety of Geranium argenteum with flowers deep red instead of the usual pink, and contrasting sharply with the silvery green of the neat rosette. In the background were some plants of a white anchusa raised by the firm and, although blue is rare in the garden and white is common, yet this albino, besides serving as a foil to show up the type, has a certain frosty beauty of its own. Beside it was the



ONE OF THE FINEST OF ALL DWARF RHODODENDRONS. R. MYRTILLOIDES.

THE HANDSOME BLOSSOMS OF CISTUS LADANIFERUS IMMACULATUS.

Digitized by Google

monstrous foxglove that produces a huge single petunia upright on the top of its ordinary spike of flowers. It is strongly recommended to lovers of the curious.

Among the other exhibits were the following:

Ageratum.—Messrs. Dickson and Robinson.
Alpines.—Messrs. Bakers, W. H. Rogers, Skelton and Kirby, F. K. Wood.
Antirrhinums, Clarkias, etc.—Swanley Horticultural College.
Carnations and Pinks.—Messrs. Allwood Brothers, C. Engelmann, C. H. Herbert, Stuart Low and Co.
Clematis and Other Shrubs.—Messrs. L. R. Russell and Co.
Greenhouse Plants.—Messrs. Stuart Low and Co.
Herbaceous Plants.—Messrs. Blackmore and Langdon, J. C. Allgrove, Bakers, Chalk Hill Nurseries, Harkness and Sons, K. and E. Hopkins. G. A. Miller, B. Ladhams, Rich and Co., Skelton and Kirby, W. Wells.
Lupins.—Messrs. J. Cheal, Hemsleys, Harkness and Sons, Dickson and Robinson.
Orchids.—Messrs. Sanders and Stuart Low.
Pelargoniums.—Messrs. Godfrey and Son.
Roses.—Messrs. George Prince and J. H. Pemberton.

NEW AND RARE PLANTS.

CISTUS LADANIFERUS IMMACULATUS.—This is a beautiful pure white unspotted form of the species sometimes known as albiflorus. The flowers, almost 4ins. across, with broad white petals slightly crimped at their margins, are borne solitary at the end of the slender side branches. Award of merit. Shown by Sir William Lawrence.

RHODODENDRON MYRTILLOIDES WARD 3172.—One of the rare species of this genus, largely owing to its late introduction and from its appearance, it is one of the finest of all our dwarf rhododendrons. It is a dwarf shrub reaching about 6ins. high, bearing numerous solitary flowers which resemble waxen bells of a firm texture. In colour, they are of a light pink to plum colour and inside a shade of reddish white. Award of merit. Shown by Mr. Lionel de Rothschild.

ECHIUM WILDPRETII.—This species is a native of the Canaries and is not hardy in this country. It is a tall soft hairy biennial with simple erect stems reaching a height of about 3ft. It is very floriferous, bearing numerous pale dull red flowers, the colour of which is relieved by the exserted filaments, in a long terminal spike. Award of merit. Shown by Mr. Charles T. Musgrave, Godalming.

RHODODENDRON MRS. WILLIAM WATSON.—An attractive hybrid, carrying loose trusses of white flowers blotched with reddish crimson. The trusses of bloom are carried well up from the foliage. The individual flowers are about 2ins. across. Award of merit.

RHODODENDRON MRS. A. C. KENRICK.—This variety carries loose trusses of pink-edged, prettily crisped flowers, the colour shading to white in the throat. The petals are slightly blotched. Award of merit.

RHODODENDRON LADY DE ROTHSCHILD.—The whitish to pink flowers, almost 2½ins. across, of this hybrid are carried in loose trusses standing out from the dull green of the foliage. Blotches of a dark maroon shade occur on the petals. Award of merit. These three hybrids were all shown by the executors of the late Anthony Waterer.

RHODODENDRON IDA WATERER.—This attractive variety carries fairly large, frilled flowers of a violet-rose tint.

RHODODENDRON TED WATERER.—The wide, rather flattened blossoms of this form are white in colour, tinged with lavender at the edges. On one of the petals blotches of yellow occur.

RHODODENDRON DISCOLOR HYBRID.—This is a showy variety, carrying expanded, long tubed flowers of a rich pink colour. The petals are frilled.

RHODODENDRON MONSTROUS.—The large trusses of the handsome rose-pink blossoms undoubtedly give the varietal name to this hybrid. The flowers vary a little in colour.

The above four hybrids all received awards of merit, and were shown by Messrs. Waterer, Sons and Crisp.

SALVIA HARBINGER.—This appears to be a fine variety for summer bedding purposes, being sturdy and carrying large spikes of handsome scarlet flowers. Award of merit. Shown by Messrs. Watkins and Simpson.

CARNATION FROYLE BEAUTY.—This is a fine border variety, with blooms of a salmon-apricot shade. Award of merit Shown by Mrs. P. B. Summers, Froyle Place, Alton.

HEUCHERA PINK DELIGHT.—This does not appear to carry any distinctive marks from other varieties, unless it be its rather tall, graceful habit. Shown by Mr. G. Miller.

PYRETHRUM AVALANCHE.—This variety carries large single, almost pure white save for a pinkish tinge, blooms, 3–3½ins. across. Some of the individual blooms carried four rows of petals, while others had only two. The flowers were well carried on tall and fairly erect stems. Award of merit. Shown by Mr. H. Robinson, Hinckley.

HYDRANGEA NEIGE ORLEANAISE.—This variety certainly represents a distinct advance in white hydrangeas. It is of a good pure white, of neat habit, with bright green foliage, while the trusses of flower are really immense. Award of merit. Shown by Mr. H. J. Jones, Lewisham.

HYDRANGEA PASTEUR.—Another excellent new variety carrying huge trusses of large almost salmon pink flowers, shading to a deeper tint in the eye. The trusses are oval in shape and about 15 ins. across. Award of merit. Shown by Mr. H. J. Jones, Lewisham.

AGERATUM LITTLE BLUE CLOUD.—This is a small and compact variety of neat and attractive habit, reaching a height of about 4–6ins. It is very floriferous, carrying numerous flower heads of a pure shade of blue. Award of merit. Shown by Messrs. Dickson and Robinson, Manchester.

ORCHIDS.

MILTONIA VEXILLARIA RAJAH.—A remarkable form of this well known plant, the rose-tinted flower having an unusually large crimson-purple blotch on the labellum. It had been obtained by crossing a typical form of M. vexillaria with the variety called G. D. Owen, the latter distinguished by a blotch of similar colour, but not covering so extensive an area. Award of merit. Shown by Messrs. Black and Flory, Slough.

ODONTOGLOSSUM CRISPUM VAR. RENOWN.—A garden-raised plant of this Colombian species. The spike bore six large flowers, the segments broadly developed, white except for a reddish blotch on the centre of the labellum. Award of merit. Shown by Mr. J. J. Bolton, Claygate, Surrey.

ODONTIODA OPAL, GERRISH'S VARIETY.—An immature seedling obtained by crossing Odontioda Cooksoniæ with Odontoglossum Eximillus. The single flower, of deep rose tint heavily blotched with reddish scarlet, the labellum deep rose and with a red blotch near the yellow crest. Preliminary certificate. Shown by Mr. R. Gerrish, Milford Manor.

MOTOR MOWING MACHINES

THERE is no more arduous task in the garden than the mowing of the lawn, and any inventions which enable this work to be carried out quickly, cheaply and with the minimum amount of labour are bound to make a strong appeal to the public. The power-driven mowers now on the market are the result of the most exhaustive tests and experiments on the part of the various manufacturers and for those fortunate, or in some cases unfortunate, folk who possess large estates, the modern motor mowing machine is almost to be regarded as a necessity. The English climate certainly has many faults, but as long as cultivation is not neglected, the abundant rainfall and absence of tropical sunshine are largely responsible for producing the most beautiful lawns in the world. Except during periods of severe frost or when the ground is water-logged, the grass should be mown regularly all the year round, and, thanks to the help of the motor mower, this work can be done rapidly and efficiently. There will soon be few cricket, tennis

THE "AUTOMO," A LIGHTWEIGHT MACHINE

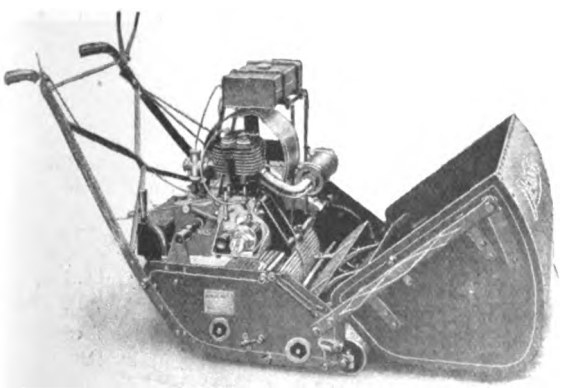
and golf clubs which are not provided with these machines. Improvements and extra refinements will, of course, be adopted each year, and both makers and garden owners eagerly look forward to the production of a light but strong machine, the price of which will be sufficiently low to encourage anyone who has a small lawn to purchase one and thereby be able to feel in future that grass-cutting is a pleasure rather than a labour. The Royal Horticultural Society is to be congratulated on organising an official trial of motor mowing machines, but it would be far better another time to arrange for trials to be carried out, if possible, on some private lawns, as the grounds where the trials were held in Regent's Park were far from ideal for the purpose. Not only was the grass rank and coarse, but the ground was, in places, very uneven, and in one case, at least, the operator in charge of a machine only just stopped in time to avoid running over a large piece of broken brick. The trials were of great interest, inasmuch as most of the leading makers were represented, but they could hardly be regarded as a

Digitized by Google

fair test of cutting private lawns, as it was in most cases impossible, owing to the irregularity of the ground, to set the rollers and knives to cut the grass really close. It would be advisable, also, for tests to be made with regard to heating, fuel consumption and the work of the machines on gradients. Among the smaller machines, the "Automo Super Lawn Mower" deserves attention. It is made in Nottingham, and a point of special importance for garden owners who intend to do their own mowing is that no spanners are required for the ordinary running adjustments. The rollers and also the knives are easily and quickly adjusted by turning a large hand wheel, and this system has been adopted under licence from the makers of the J.P. Lawn Mowers. The running cost is low, and the makers claim that the average cost of petrol and oil for 2,000 square yds. is only the small sum of threepence. With one of these machines it should be an easy matter to mow a tennis lawn regularly in one's spare time, and the cost of the labour and time saved would go a long way towards paying for the cost of the machine in the first season.

The water-cooled Governor machines made by John Shaw and Sons, Wolverhampton, should certainly be equal to many years of hard work, and every possible contingency likely to be encountered while cutting grass seems to have been anticipated.

It was, I believe, in 1832, that Ransomes of Ipswich made their first lawn mower, and ever since then the firm of Ransomes, Sims and Jefferies, Limited, have turned out lawn-mowing machines of the highest quality. The 16in. model fitted with a 1½ h.p. engine is a splendid machine for small gardens, while for use in grounds up to 5 acres the 24in. and 30in. models can be recommended.



THE "DENNIS" MOTOR MOWER.

The Auto-Mower Engineering Company, Limited, of Norton St. Philip, appeared to be making light work of the grass which their machines were set to cut at the official trials, and these machines have given great satisfaction to those who have purchased the various models during the last few years.

The M.P. (Mower Pusher) can be attached to any mowing machine in from five to ten minutes, and special fittings are supplied to fit any of the standard machines. The M.P. is fitted with a seat so that there is no need to even walk behind the machine while it is at work. When the mowing is completed, a standard fitting allows an ordinary garden roller to be coupled up ready for rolling the lawn.

Another very satisfactory machine which can be fitted to any lawn mower, and which will, therefore, save scrapping a satisfactory machine already in use, is the Rendle Motor Mower. It is made in two models, of which that known as "A" is capable of pushing mowing machines up to 28ins. and rollers up to 14cwt. Model B will propel mowing machines up to 36ins. and rollers up to 1½ tons. This is a thoroughly sound little machine, and at a cost of 1d. it will cut, with a 24in. machine, 1,000 sq. yds. in fifteen minutes.

The range of motor mowers made by Alexander Shanks and Son, Limited, ranges from a large 42in. model costing over £300 down to the very popular 16in. Wizard, which is retailed at £45. This last machine is of simple design, strongly constructed, and is driven by a 1½ h.p. engine of the two-stroke type.

Thomas Green and Sons, Limited, have been makers of lawn mowers for nearly a century. Their 16in., 20in. and 24in. motor mowers are fitted with kick starters, thereby eliminating the risk of personal injury from backfire, and this I consider a most important point. The only real limit to the daywork that may be carried out by these machines is the walking power of the actual operator.

Dennis Brothers, Limited, of Guildford, have long been famous for their motor lorries and fire-engines, and it stands to reason that any motor lawn mower made in their works will be of high quality. The machines are driven by a 4 h.p. engine, which is powerful enough to cut the grass on quite steep gradients. The engine will tick over very sweetly, and if a trailer seat is fitted it will easily travel on the level up to five miles an hour. A great point about the Dennis machine is that the driving rollers are fitted with differential gear, so that the machine actually drives round bends.

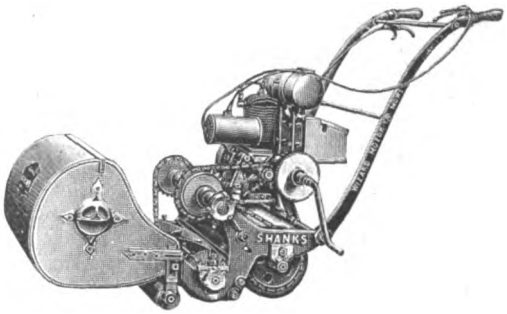
The Atco machines, made by C. H. Pugh, Limited, of Birmingham, are so well known that it is hardly necessary to refer to them. Mr. Andrews, the firm's very capable sales manager, deserves the success which he has achieved.

The future of the motor lawn-mowing machine is assured, and the demand is bound to increase year by year as the result of the successful reports of satisfied users. R. W. ASCROFT.

REPORT OF TRIAL OF MOTOR LAWN MOWERS AND ACCESSORIES.

On the reports of the judges appointed for this trial the Council of the Royal Horticultural Society has now made the following awards:

Awards of Merit.—42in. motor lawn mower from Messrs. Thomas Green, Limited, for use on sports grounds and similar areas. 30 in. motor from Messrs. Shanks and Son, Limited, for lawns. 30in. motor lawn mower from Messrs. Dennis Brothers, Limited, for lawns. 24in. motor lawn mower "Jehu,"



THE "WIZARD" MACHINE OF MESSRS. SHANKS AND SON.

from Messrs. Alexander Shanks; 24in. motor lawn mower from Messrs. Dennis; 24in. heavy motor lawn mower with trailer seat, from Messrs. Thomas Green; 20in. light motor lawn mower with trailer seat, from Messrs. Thomas Green; and 16in. "Wizard" motor lawn mower from Messrs. Shanks for small lawns.

Highly Commended.—30in. Atco motor mower with seat, from Messrs. C. H. Pugh, Limited, for large lawns; 24in. auto-mower with seat, from the Auto-Mower Engineering Company; 18in. Auto-mower with seat from the Auto-Mower Engineering Company; 16in. Atco motor mower, from Messrs. C. H. Pugh, Limited, for small lawns; 16in. Atco motor mower with twelve blades and special sole plate from Messrs. C. H. Pugh, Limited, for very fine lawns; G.N. motor attachment for lawn mowers, from Messrs. G.N., Limited; motor pusher with forecarriage, from the M.P. Company, Limited, for drawing lawn mowers, etc.; Rendle motor mower attachment, from W. Edgecumbe, Rendle and Co., Limited, for pushing lawn mowers; trailer seat for motor mowers, from Dennis Brothers.

Commended.—22in. "Governor" water-cooled motor lawn mower from Messrs. John Shaw and Sons; 22in. "New Godiva" motor mower, from the Godiva Engineering Company, Limited; 22in. Atco motor lawn mower, from Messrs. C. H. Pugh, Limited: 16in. Automo motor lawn mower, from Messrs. F. Mitchell; motor pusher, from M.P. Company, Limited, for pushing lawn mowers.

The R.H.S. Amateur Flower Show.—Owing to the difficulty which amateurs find in deciding in advance whether their flowers will be at their best at the date of the show, it has been decided to postpone the latest date for the acceptance of entries until Saturday, June 20th.

The Knaphill Nursery.—It is announced that the well known rhododendron nursery belonging to the late Mr. Anthony Waterer at Knaphill, near Woking, will be submitted to auction by Messrs. Buckland and Sons at Woking on July 9th. The wonderful blooms are now almost at their perfection and we understand the nursery will be open for inspection by the public during the coming week or so.

SIMPLE GARDENING

FRESH VEGETABLES AND SALADS.

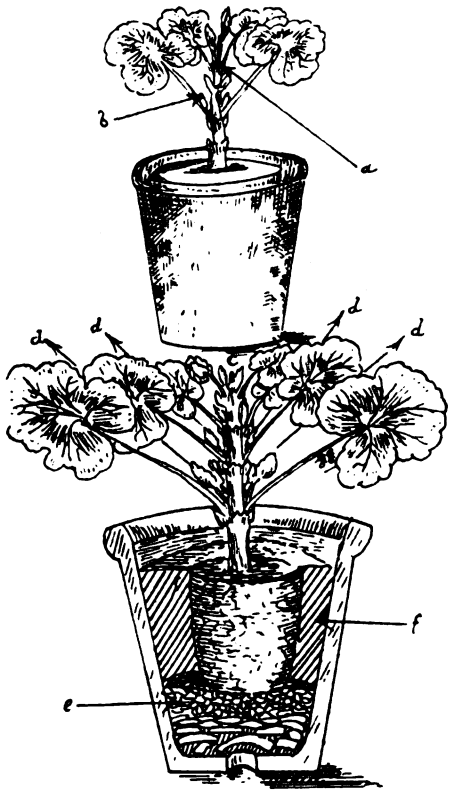
YOUNG vegetables and salads may be obtained late in the summer and during the early part of the autumn if seeds of suitable kinds and varieties are sown now, and, in the case of salads, at intervals till the end of July. I am referring to those salad plants, raised from the latest sowings, that grow to a condition fit for using in a few weeks' time. The sowing of seeds at this time of the year is not a new idea, but there are thousands of amateur cultivators who do not adopt the plan. Ground should not be allowed to remain uncropped at this season. In four out of five gardens there are small quarters where quickly maturing crops may be grown. Furthermore, the lifting of early potatoes and the clearing away of early rows of peas, broad beans and spring cabbages, leaves ground vacant. The stump-rooted varieties of carrots are valuable for sowing now. The seeds germinate quickly, so, also, do beet seeds, and very nice roots of both kinds will be available by the end of October. The resultant seedlings should be thinned out at an early stage to allow those plants left to thrive. The earliest cauliflowers should be selected, the seeds sown in the drills thinly and the young plants duly thinned out; it will not answer if transplanting is done. Turnips are splendid, and sowings of these and lettuce may be made monthly till the end of August. Early sorts of dwarf or French beans often prove the tenderest from sowings at this time, but peas sometimes mildew badly. It is very interesting and remunerative work, and keeps the garden full of good things.

FINAL POTTING OF CHRYSANTHEMUMS.

Before the end of June all plants grown in pots should be placed in their flowering pots and in their summer quarters, where they should remain till, approximately, the last week in September. I find that many inexperienced cultivators think it quite necessary to mix a compost of many parts to ensure success. The main ingredient should be good fibrous loam in which the grass has died—it should form nearly two-thirds; leaf-soil and coarse sand, one-third. To a bushel of the above combined parts add a 5in. potful of bonemeal and wood ashes, respectively, and a 6in. potful of old lime rubble broken up finely. The whole should be thoroughly mixed. Pots varying in size from 7¼ins. to 11ins. may be used, the first for single spring-rooted plants of the weaker-growing sorts, and the 8in., 9in., 10in. and 11in. pots for the stronger, winter-rooted specimens. But it is rarely advisable to place one plant in the 11in. size; two plants will not be too many unless very large specimen plants, bearing many blooms, are required. The cultivator should see that the plants are watered a few hours before they are potted. In all except the two largest-sized pots one big crock will be sufficient if covered with rather lumpy fibrous loam before any general compost is put in. The new soil should be made firm with the potting-stick and room left at the top for water. Staking, too, should be carefully done, as young shoots are too valuable to lose now. Very careful watering is essential for three weeks after potting.

SUMMER TREATMENT OF ZONAL PELARGONIUMS IN POTS.

The zonal pelargonium is a soft-wooded plant that grows luxuriantly in good soil, and its sappiness is increased when the plants are not fully exposed to the light and air. If well baked in the sun from the end of June till the end of August the stems will be short-jointed, the leaf-stalks short, and the leaves thick and almost leathery. Such



specimens are going to prove highly useful throughout the winter months if they are housed in a light structure, well ventilated and subjected to a comparatively dry atmosphere and a temperature approaching summer heat. Opposite conditions to the above-named ones would mean wholesale disappointment to the cultivator. A whole greenhouse, or one stage in it, filled with well grown nicely ripened plants in early autumn will ensure a never-ceasing interest throughout the winter months. These plants are old favourites, and if only on account of the cheery brightness of their flowers, they will continue to be so with amateurs. The position of the plants outside should be a warm one as stated, but careful watering and feeding are essential points. To obtain well balanced plants is another important point; this is done by judicious stopping, as we shall now see. At *a* the point of the young plant is pinched off; side shoots at once begin to grow at *b*. Either before, or soon after, re-pot; the centre shoot, *c*, again begins to lead; *d*, *d*, *d*, *d*, will also soon be filled with side shoots. Stop these, in turn, in August and always remove flower-buds to end of that month. At *e* good essential pot drainage is shown; and at *f*, the new compost. Bonemeal forms a grand ingredient.

TRAINING GRAPE VINES.

Where, I wonder, is the amateur cultivator who does not like to listen to the sound of dropping grape berries as he is engaged, in the cool of the evening or early morning, in the work of thinning well set bunches of grapes? To secure such fine bunches we must look to the training of the shoots, so that the strength of the vine is directed to the perfecting of main leaves, those of lateral leaves and the stems of the shoots bearing the bunches. Of course, the vine rods are already a fixture for this year; they are, usually, tied to wires too near to the glass, and then there is not sufficient space for the current year's shoots and leaves to grow in and be, as they should, clear of the glass. Where such a condition obtains now, note should be taken of it, so that a better arrangement can be made next year. The side branches, bearing the bunches, always grow upwards towards the roof glass. It is advisable, but not absolutely necessary, to bring them to the wires, but this can only be done safely a little at a time. The variety Black Alicante is very brittle when young and whole shoots are lost if unduly forced down. Mostly, it is safe to tie finally to the wires directly the berries are set. The plan should be to cover entirely, but evenly, the roof space with thick, leathery main leaves and lateral leaves. Stop the branches two or three joints beyond the bunch of grapes and the side laterals beyond the first leaf, removing altogether all sub-laterals while quite small.

MULCHING AND TOP-DRESSING.

Mulching and top-dressing, to a certain extent, serve the same purpose. But there is a real difference. The top-dressing materials should be richer than the main body of soil used in potting or planting in bulk. When we pot or plant we are supplying a compost for a few roots to benefit by it and, on account of the fewness of the roots, we must be careful to supply such mixtures as will induce new roots to enter them and remain sound, fibrous, for a long time. When top-dressings are applied they are intended as supplementary to previous composts in bulk and are to keep up, if not increase, the vigour of the plants after their roots have exhausted the nutriment in the first applied compost. Mulching means the application of substances which act temporarily, preserve surface roots, encourage their increase and conserve the moisture of the soil by preventing wholesale evaporation.

GEORGE GARNER.

THE GARDEN

VOL. LXXXIX.—No. 2797. JUNE 27, 1925

Price Threepence. Yearly Subscription, Inland, 17s. 4d.; Foreign, 17s. 4d. Registered at the General Post Office as a Newspaper and for Canadian Magazine Post.

Editorial Offices: 20, TAVISTOCK STREET, COVENT GARDEN, W.C.2. *Offices for Advertisements:* 6-11, SOUTHAMPTON STREET, STRAND, W.C.2.

Entered as Second-class Matter at the New York, N.Y., Post Office.

IT IS AT THIS PERIOD OF THE YEAR WHEN THE BLENDING AND TONES OF COLOURS AND COLOUR SCHEMES ARE SEEN TO BEST ADVANTAGE THAT NOTES OF IMPROVEMENTS TO BE CARRIED OUT IN THE LATER MONTHS SHOULD BE MADE. HERE WE HAVE A DOUBLE BORDER IN WHICH PINKS, BLUES, MAUVES AND WHITES MINGLE TOGETHER WITHOUT A TRACE OF HARSHNESS, AND PRODUCE AN EFFECT WHICH IS WHOLLY PLEASING TO THE EYE.

HARDY CYPRIPEDIUMS at CHELSEA

BY GURNEY WILSON.

THE beautiful group of hardy cypripediums exhibited at the Chelsea Show by Mr. Albert C. Burrage of Beverly Farm, Mass., U.S.A., was not only an entirely unexpected event, but it formed one of the outstanding features of the whole Show, and the award of a silver-gilt Lindley medal was suitably given in recognition of its scientific and educational value. Considering the remarkably fine specimens that were contained in this exhibit, the actual collecting of them must have been a matter of much explorative work. This was followed by establishing the plants in shallow boxes, sufficiently strong for exportation to England, and filled with native soil. On arrival in England, Mr. E. M. Preston of The Warren, Hayes, Kent, very kindly gave every facility for the plants to be brought into flower in his garden, while the practical duties were ably carried out by his gardener, Mr. C. F. Wood. As these boxes of dormant plants arrived in a solid and frozen state, great anxiety was felt by the various people responsible for this group that the different species might not all be in flower for the opening day of the Show. Thanks to elaborate directions prepared in America, to the transmission of English weather reports, to cable messages as to the plants' progress in Kent, and largely to careful attention to cultural details, everything came out successfully.

CYPRIPEDIUM PUBESCENS WHICH BEARS A STRONG RESEMBLANCE TO C. PARVIFLORUM.

ONE OF THE "DIFFICULT" NORTH AMERICAN SPECIES TO FORCE, CYPRIPEDIUM REGINÆ OR SPECTABILE.

This imposing group occupied about 400 sq. ft. The pine trees formed a background, and under their shade were arranged the many plants of Cypripedium acaule, thus following the natural conditions under which this species exists in its native habitat. The history of this plant goes back to the year 1789, the date of Aiton's "Hortus Kewensis." It is commonly known as the pink moccasin flower. The front of the labellum is folded in from the sides, and the two margins meet except for a narrow slit, and they fold in such a way that the sides slope all round and down to the narrow opening. The two basal openings are several times larger than the slit in front, which, however, opens inwards with a very slight pressure, so that a small insect alighting on the pouch would readily find ingress, but could not return, and must leave by way of the basal openings after first passing the stigma, and then rubbing against the sticky pollen which would be carried to the next flower visited. A rare albino variety occurs and differs from the type in having light green sepals and petals and a pure white labellum or pouch. C. acaule is the easiest of all the American cypripediums to force, and takes but four or five weeks to reach the flowering stage.

The central zone of this exhibit was composed of many superb specimens of Cypripedium parviflorum and C. pubescens. These plants closely resemble one another, and as the former was described in the year 1791 and the latter in 1804, C. pubescens is sometimes referred to as a variety of C. parviflorum. The larger flowers are all borne by C. pubescens, whose sepals and petals are often lighter in colour. But in Mr. Burrage's plants several masses had both kinds intermixed, and this supported the previously recorded opinion that not only are they one and the same species, but that one variety might pass into the other when influenced by different climatic conditions. Rolfe referred both these plants to the earlier name of C. hirsutum applied by Miller in 1768, and as the entire plant is clothed with hairs, the name is certainly appropriate. But as no type of Miller's species is extant, and great uncertainty exists, Professor Oakes Ames considers it

Digitized by Google

unwise to adopt this earlier name. The flowers of C. parviflorum are sweetly scented, and on this account it is generally known as the fragrant yellow moccasin flower. The experience of American cultivators is that the flowers of C. parviflorum open slowly, but last a long time when matured, longer than those of C. pubescens. Both bear a strong resemblance to those of the English C. Calceolus, but Rolfe has stated that in the American plant the staminode is trulliform-ovate and flat, while in C. Calceolus it is oblong, concave or duplicate.

The foreground of this remarkable exhibit comprised many superb masses of Cypripedium reginæ, perhaps better known to many under the name C. spectabile. Although both names are appropriate, the former meaning queenly appearance and the latter showy, C. reginæ must be adopted, as it dates from 1788, when the plant was described by Walter in "Flora Caroliniana," thus three years earlier than the publishing of C. spectabile by Salisbury, which occurred in 1791. In the opinion of several authorities, the plants shown by Mr. Burrage were the finest that had ever been exhibited, the central specimen having as many as fifty vigorous growths. This is one of the difficult plants to force, for if the temperature is maintained at over 55° the growths fail to produce flowers. Under the more natural conditions of a lower temperature the growths yield from one to four showy flowers,

CYPRIPEDIUM ACAULE, THE PINK MOCCASIN FLOWER.

whitish tinged with pink, the shoe-shaped labellum of a much deeper pink-purple colour. Although chiefly recognised as a North American species, it has been discovered on the borders of China and Tibet. C. reginæ album, in which the colour has vanished from the labellum, leaving it snow-white, flowered at Kew in 1897, but a much earlier record is the plant figured by Sweet ("British Flower Garden," III, t. 240) under the name C. spectabile album, thus reviving the old specific name of C. album applied to this plant by Aiton in 1789 ("Hortus Kewensis"), or just a year after its original name of C. reginæ.

Cypripedium arietinum was also well represented by numerous plants prettily arranged between those of the much larger C. reginæ. The specific name arietinum refers to the conical labellum resembling a ram's head, and these flowers, borne singly on the apex of a slender growth some 6ins. to 9in. high, possess distinctive features that more than compensate for their comparatively small dimensions. The sight of over a hundred flowers of this species effectively arranged among other members of the genus will long be remembered, while the little stream of water, bordered by Osmunda regalis, gave a most finishing and natural border line. At each end were five specimens of Tsuga canadensis, also from the United States, while a few rocks and an abundance of moss completed the exhibit.

The POSSIBILITIES of SOUTH COAST GARDENING

RESIDENTS in Scotland, the north of England and the north midlands have the impression that practically all kinds of plants may be grown on the south coast without being damaged by severe frosts in winter and late spring frosts. There are exceptions, of course, as some northern residents realise, and frosts more severe than the average do come in the south. I remember two long, hard frosts during the forty years I have lived in Hampshire, and much damage was done to plants not protected or covered with snow. But, generally, I can say from experience, the possibilities of gardening in and around Bournemouth and the south coast are very great, and enthusiasts know this and take a lead in matters horticultural. Many gardening societies have been in existence for a long time and new ones are formed every year.

Rare trees and shrubs receive much attention and thrive remarkably well. Herbaceous, rock and alpine plants are extensively grown and with great success, not only by experts, but amateurs, too. With the exception of certain districts, fruit is satisfactorily grown. In many parts it is of the highest quality. Pears fruit well on walls, but only moderately on orchard or open border trees. Plums, in the districts extending from beyond Poole Harbour to Southampton, are not a success unless lime is added to the soil. The latter varies in composition considerably. Sand, gravel, light, medium and heavy loams are met with in quite small areas, and then, suddenly, one steps upon peat or clayey ground which produces wonderfully fine crops of wheat—and roses.

The latter remind me of Mr. Walter Child Clark's roses at Micheldever House, Bournemouth. This gentleman has made a rose paradise among the pines of his garden. Scarcely a cartload of the original soil was suitable for roses, but good loam was used to replace the peat and gravel removed to form beds, and with wonderful results. I think the best time to see these flowers is in the evening when the sun is setting. The flowers are seen in masses in beds and even trailing over bushes and round the gaunt trunks of the pines—a charming picture, indeed, the subdued light enabling the eyes to see the delicacy of the colour of the petals to the full.

On the other side of Bournemouth, nearer Poole, Mr. J. J. Norton has established an almost perfect collection of rhododendrons, which his able gardener, Mr. C. Nippard, maintains in fine health. At Branksome Dene Mrs. Cassel has a large garden and a most interesting woodland. Herbaceous borders have, at a suitable distance, a background of trees and shrubs. Grass here is used in place of gravel paths, and forms a fitting setting to the azaleas and other numerous spring-flowering trees and shrubs and the bulbs. This garden is situated on the cliffs, and is exposed to the full force of the south-west gales, but there is ample protection afforded by the many acres of pines and other trees. Of course, protection of choice subjects is one of the things first considered when a garden is formed in these parts. Pinus insignis, evergreen oaks, Cupressus macrocarpa are, probably, the most generally planted as wind screens, according to the size of the garden and its grounds.

The Bournemouth Public Gardens contain many rare trees and shrubs and also border plants. Every year there is a judicious change in the bedding-out arrangements, and these afford visitors every opportunity to study and copy them if so minded.

Pines and other kinds of trees are left in natural formation where possible, so that Nature is seen everywhere, even in the private gardens around dwelling-houses, thus avoiding formality, and intermingling, as it were, the work of man with that of Nature. What I may term sub-tropical plants may be used with great effect in the flower garden during the summer months, and made to resemble the groups generally seen in our greenhouses and conservatories. The natural surroundings in existing gardens, and also in districts where new gardens are to be, or may be, formed, enhance the beauty of such beds.

Digitized by Google

Rock and alpine gardens, grottos, pergolas and those delightful, restful woodland paths where one can enjoy the early spring flowers and the baby buds on the branches of tree and shrub within hearing of cuckoo, woodpigeon and nightingale are all attainable, and do not entail much seeking.

The Swanage stone is near and known throughout the country as ideal for rock and alpine plants In the writer's own garden the stones prove their adaptability, the roots of the plants soon cling to them and appear to be quite at home. Suitable timber for pergolas is still more easily obtained and is not expensive.

At Exbury House, the charming seat of Mr. Lionel de Rothschild, large woods have been cleared of undergrowth, the soil—clay, peat, loam and gravel mixed, in places—dug up, and thousands of rhododendrons and azaleas with other choice shrubs planted. Lakes, rockeries and waterfalls have been planned and ably carried out in a very natural manner. Near by is the equally attractive grounds of Mr. Ingram Whittaker at Pylewell Park. In a portion of the water garden ferns flourish in positions submerged by tidal waters at times. Rhododendrons and choice ornamental-leaved and flowering shrubs from distant countries find a home. A little to the north, overlooking Southampton Water, grows probably one of the finest specimens of the deciduous cypress, Taxodium distichum, in the country. It towers to a height of more than 100ft., has a trunk girth at 4ft. from the ground of nearly 15ft. Magnolias and camellias in the same garden have attained to great size, and the blue hydrangea also. These gardens and the extensive woods contain fine specimens of evergreen and deciduous trees, and belong to Mr. Maldwin Drummond, Cadland Park. I have seen the whole end of one dwelling-house in this district entirely covered with Solanum jasminoides within 100ft. of the cliff edge. At Hinton, Admiral Sir George Meyrick's charming old country house near Christchurch, conifers do well, also the gunnera and Fatsia japonica, respectively, grow to a large size, the last named being about 20ft. high and as far through. At the Hinton Vicarage, the vicar, the Rev. C. O. S. Hatton, raised, among other plants, Eucalyptus globulus from seed. One tree is now 50ft. high and has not been many years in attaining this size. In the gardens of Ossemsley Manor Lady Gatty has what I may term a meadow filled with irises—gems, indeed, where many others are set, too.

I have referred to a few large gardens mainly, but similar conditions obtain in small and medium-sized ones almost without number. Torquay and Devon way may be similarly referred to. Still choicer subjects flourish and the growth is a little earlier than on the mid south coast, but I think I have said enough to convince readers of THE GARDEN that the possibilities of gardening on the south coast are great and without finale.

GEORGE GARNER.

MOSQUITO CONTROL IN GARDENS

BY G. FOX WILSON.

WITH the keenly anticipated advent of summer, town and country dwellers are hoping that the climatic conditions of last year will be reversed and that we shall be able to take full advantage of our gardens and the open air. The winter and early spring months have been allotted more than their average rainfall, so that we may expect a plague of mosquitoes with the coming of warmer days. If, however, we experience a dry summer, there is still a chance that a plague of mosquitoes will appear. Certain species, such as Anopheles maculipennis and Culex pipiens (the so-called gnat), are not affected to any degree by drought, for the former breeds along the sides of ponds and lakes and the latter, a domestic species, will breed in most of the artificial water supplies used by man.

OLD TINS FILLED WITH STAGNANT WATER FORM EXCELLENT BREEDING PLACES.

No true garden lover allows his plants to become infested with insect pests without using his utmost energy to combat them, but the same people take no remedial measures to ensure against countless numbers of mosquitoes, which too often make the garden a place of torment during summer evenings.

In Britain there are about twenty-one species of mosquitoes, including the two well known genera, anopheles (the so-called mosquito) and culex (the common gnat). The blood-sucking propensity is confined to the female mosquito, which lays, in the case of anopheles, from forty to one hundred eggs singly on the surface of the water. The eggs of culex species are spindle-shaped and attached in raft-like structures, comprising as many as four hundred. The eggs give rise to larvæ (the "wrigglers" of water butts), which for respiratory purposes either lie parallel to the surface of the water (anophelines), or hang downwards in a Y-shaped position (culicines). When the larvæ are fully grown, they turn into pupæ, which are comma-shaped and breathe at the water surface through trumpet-like "ears," situated just behind the head. After a given time, depending on weather conditions and temperature, a slit appears along the back of the pupa, out of which escapes the adult mosquito.

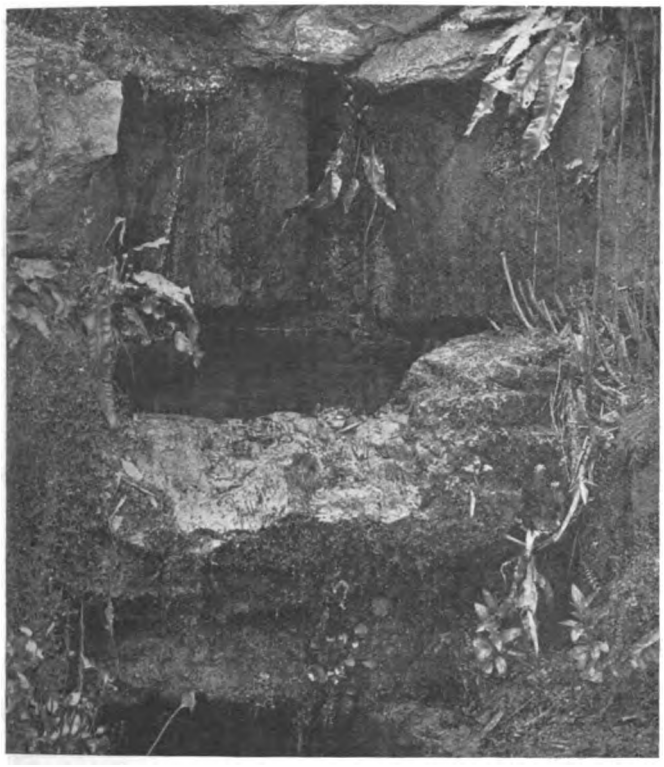
When large numbers of mosquitoes are found in a house or garden, it is evident that the breeding place is near, the distance ranging from fifty to two hundred yards, although a mile is not too distant if human habitations are the goal.

There are two methods of control: (i) preventive, that is to prevent egg-laying, and (ii) remedial measures, to destroy eggs, larvæ and pupæ in the water and adults during hibernation and diurnal quiescence.

The chief breeding places in gardens are:

1.—Ornamental ponds, including rockery pools and fountains. Such situations are the favourite resorts sought for by Culex pipiens, and constant attention should be paid to such stagnant water supplies. All sources of stagnant water should be viewed with suspicion, especially where decomposing organic matter occurs. It is desirable that larvivorous fish, such as minnows or gold fish, be kept wherever practicable, for these

Digitized by Google



A TYPICAL ROCKERY POOL.

will devour the egg masses and larvæ, provided that the latter are unable to seek shelter beneath water plants, such as nymphæas, aponogeton and duckweed, and under overgrowing herbage, algæ and debris. All duckweed, algæ and debris should be periodically cleared so that the fish may have full play.

2.—Birds' baths. It is not uncommon to find egg masses and larvæ in water-holding garden furniture. The water should be renewed every week, care being taken that all egg masses and algæ clinging to the sides of the bath are removed.

3.—Liquid manure tanks. Culex pipiens is not particular in its choice of water in which to oviposit. Preventive measures include the covering of all such tanks with air-tight lids or muslin-covered frames. When larvæ are found, it is advisable to apply an oil film. This kills them as they come to the surface to breathe. A larvicide may be put into the water to attain the same end.

4.—Old, disused wells. In many old gardens one finds these ideal breeding places, which should be effectually screened to prevent access to the adult mosquito bent on ovipositing.

5.—Water butts and rainwater storage tanks in glasshouses. The former should be screened to exclude mosquitoes altogether, or an oil film may be applied, which will not injure the human cuticle if the water is to be used for washing purposes. Goldfish may be kept in storage tanks in glasshouses and the tanks periodically cleared of algæ and decaying organic matter.

6.—Old, empty tins, watering cans and broken flower pots. In large gardens there is usually an accumulation of rubbish, where old tins and such like are thrown and stagnant water collects. The tins should be buried and the pots broken up for use as crocks.

7.—Gutters of sheds and glasshouses. Inattention to the accumulation of stagnant water in gutters is to be deplored and is due either to broken pipes or stoppage by fallen leaves, making ideal breeding places for mosquitoes. All gutters should be kept in repair and debris removed so that the rainwater may run away without hindrance.

8.—Holes in tree trunks. Many trees, particularly beeches, have holes in various parts of the trunk, which hold water, and in which mosquitoes, especially Anopheles plumbeus, oviposit. These should be filled in with sand or soil or sprayed every ten days with paraffin.

9.—Ditches. A much neglected part of the garden is frequently a ditch, which is allowed to become overgrown with herbage, which, together with broken branches and general rubbish, holds back the water. Great attention should be paid to these situations, for they often provide ideal conditions for excessive breeding. The sides of the ditch should be steep and clear of herbage and the water allowed to run away without impediment. If the current is fast there is little danger, but if sluggish, recourse should be taken to spray every ten days with paraffin oil or apply a larvicide.

The foregoing measures apply to the early stages of mosquitoes, but there are certain precautions to be taken with regard to the adult. In the vicinity of breeding places, large numbers of mosquitoes may be encountered sheltering in coarse herbage. Periodical cutting and burning should be done.

Where the style of wild gardening is preferred, numerous adults may be caught by placing dark lined boxes, open at one end, on trees. These situations are sought for by mosquitoes as shelter during the day. The traps should be examined every morning, the adults destroyed, and the traps reset. Species of ochlerotatus are most persistent tormentors in woods and may be captured as advised.

Summerhouses, potting and tool sheds are favourite resorts for mosquitoes to shelter in during the daylight hours and also for hibernating quarters. Where numbers are encountered, it is advisable to spray with an insecticide, such as Formalin soap, or fumigate with cresyl or carbon bisulphide, previously making the building airtight to prevent the escape of the gas.

Many gardens are situated in the vicinity of vast breeding places, such as marshes, lakes, ponds, streams and pools in disused clay pits, but little can be attempted unless the matter is taken up by the local authorities and a community campaign instituted.

The remaining factors are the question of the use of deterrents and antidotes. The former, of which there are several proprietary lotions, are preferable, and the use of such oils as those of citronella or eucalyptus, applied to the wrists, ankles and the back of the neck, will prevent one being bitten. Antidotes, such as iodine and ammonia, should be applied, as soon after the bite has been received as possible, to allay irritation and prevent blood poisoning.

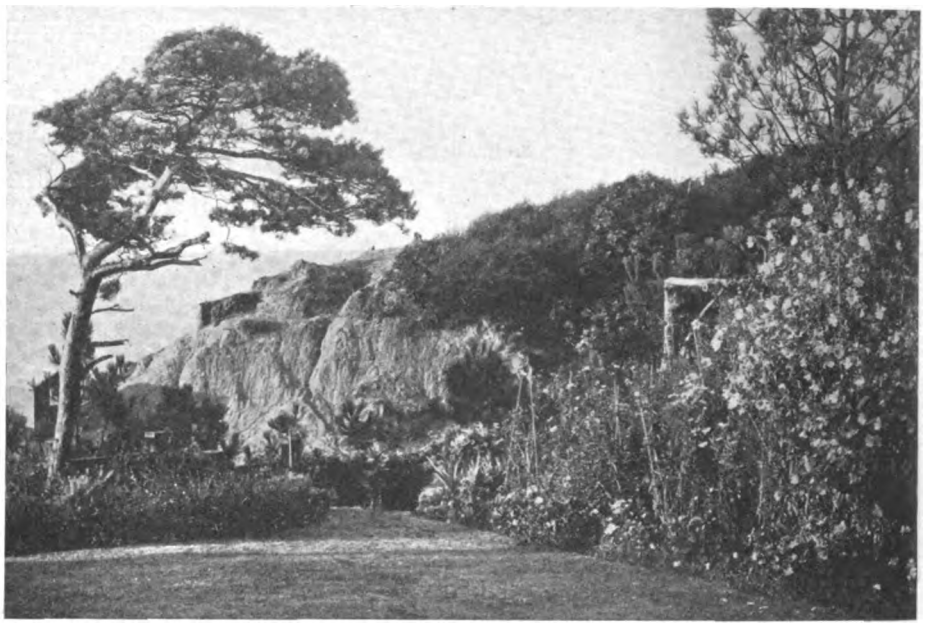
The GARDENS at UNDERWOOD, BOURNEMOUTH

THESE GARDENS SERVE AS A STRIKING EXAMPLE OF WHAT MAY BE ACCOMPLISHED WITHIN A LIMITED SPACE, AND GIVE ONE AN EXCELLENT IDEA OF THE MANY DIFFERENT KINDS OF PLANTS FROM ALPINES TO SUB-TROPICAL SPECIES WHICH FLOURISH UNDER THE CLIMATIC CONDITIONS OF THE SOUTH COAST.

SITUATED on the extreme edge of the undulated portion of the cliffs just beyond the boundary of the Borough of Bournemouth, and on the outer boundary of Dorset, is the picturesque seaside residence of Lady Wavertree. On a recent date, by the kind permission of Lady Wavertree, it was our privilege to inspect and enjoy the beauties of the gardens at "Underwood." Although not of large extent, being, approximately, about two acres, these charming gardens contain all the chief features of an extensive garden, the most striking being the fine series of rockeries. The borders are filled with the choicest subjects: colonies of heaths, rock and alpine plants, herbaceous subjects and roses are grouped all in the most appropriate parts, and, though really distinct, they all merge in a natural way. The paths, leading from one to another, broadening and narrowing as required, cannot be regarded as beginning in a number of places and abruptly ending in others, but seem to be a part of the whole, and are constructed of stone crazy work. Lady Wavertree has been indefatigable in superintending the work of carrying out her own ideas. It is only a few years since the site of these gardens was a crumbling mass of sand, gravel and clay; now they have the appearance of having been established for many years. One can, as in a fairy tale, fancy a big slice of alpine rock being suddenly transported and dropped, bodily, on this southern cliff of old England.



THE FLOWER BORDERS BACKED BY NATURAL CLIFFS WITH A VISTA OF THE OPEN SEA.

ONE OF THE MANY PATHS BORDERED BY HARDY FLOWERS LEADING TO THE SUMMERHOUSE.

Being so close to the foreshore and partially exposed to full force of the winds from the sea, as the outlook is over Poole Harbour and, more directly south, to the open sea, some protection must be provided, and this is being effected by the planting of an outer belt of Pinus insignis, evergreen oaks and black poplars. In this garden our noble dead are remembered. In one prominent corner Lady Wavertree has built a very substantial summerhouse; cut in the stone floor are the following words, "The Great War: 1914-1918. In all the fulness of their youth, They gave their lives that we might live."

It is only from this summerhouse that there is a beginning of the garden paths, and, *vice versa*, all paths seem to lead to it. In one direction there is a long path spanned by a substantial wooden pergola which is well furnished with roses and other climbing plants; on both sides the borders are filled with herbaceous plants, delphiniums being prominent occupants. On the southern side of this pergola there is a formal sunk garden, the pergola and the herbaceous plants making a charming background to it. The design of the beds is a formal one, too; in due season they are filled with old favourites: wallflowers, violas, bulbs and, in the snug corner beds, blue delphiniums. The low walls are being furnished with suitable subjects, the idea being to establish, mainly, masses of aubrietias. Here, too, in close proximity, is a big clump of Rhododendron Alice. The next path, to the south of the sunk garden, is bordered by masses of Azalea mollis, prominent among a wealth of old-world flowers; again, we look upon a fine group of Rhododendron Pink Pearl, with laburnum and roses on trellis as a background.

The next path is bordered by lavender hedges, quite low, the principal occupants of the borders being roses and lilies. In a recess the main collection of roses is grouped, and yet another path is flanked by poppies and lilies, heliotrope and standard

Digitized by Google

pink roses. Rounding a corner one suddenly comes to low walls, nicely covered with suitable plants, dwarf shrubs at the foot encroaching on the paved way which leads directly under the imposing-looking Italian pergola; at the end of this pergola, forming a cul de sac, we see a most refreshing fern grotto, rapidly becoming clothed with ferns; turning to the right one looks down upon a very imposing bank of rocks forming a sheer drop of nearly 30ft. In this rockery, in keeping with its size, are bold masses of flowers, Lithospermum prostratum being prominent owing to its good health and free-flowering propensity.

Following the paved paths which, here, are decidedly winding and undulating, one passes over narrow shelving rocks and arrives at the moraine garden just being formed. A sun-trap, yet cool, summerhouse, designed by Lady Wavertree, is found in a corner, but one may say it is a part of this lower portion of the rock garden itself, as a portion of the cliff has been excavated and faced with stones, the flat roof being covered in with stones, also; draping the ledge directly over the house and hanging gracefully from it are trailing plants, among them, well established, being mesembryanthemum. At the lowest level there is a small pond and on its banks and the slopes above masses of yellow mimulus and irises are thriving, with a gunnera at the extreme edge of the water; the water is retained by a cemented basin and the soil around is porous.

The heath bank is delightful. The bank itself is terraced, being fronted with peat turves; the heaths are already established and look quite at home, and in a short time the whole bank will be covered. Near by is another summerhouse, on the top of a high bank, which is also terraced and planted with violets, while the rock garden Juniperus compressa trailing gracefully from the stones forms a part of the retaining walls. Peonies are doing well in various borders and colonies of pinks, Allwoodii and Mrs. Sinkins, are luxuriant.

On the lawn immediately in front of the house there are a few formal flower beds filled with summer bedding-out plants, and, on the left-hand, a long herbaceous border margined with Viola Maggie Mott and backed by a high trellis covered with climbing roses. On this lawn there is a splendid standard rose of the variety Excelsa, the trusses of flowers coming freely and very large. There are many very ancient vases, stone seats and other garden ornaments; mention may be made of a splendid Venetian well-head hundreds of years old, about 3ft. wide and the same in height, the rims grooved by the action of the ropes in those long-past years when water was drawn in the primitive way of those times. It bears the coat of arms of the Lombards, the whole being in a wonderfully good state of preservation.

Lithospermum Heavenly Blue does very well and forms a prominent feature among the rocks. Other outstanding plants here were double-flowered dwarf gorse, anchusas, Picea glauca, retinospora, dwarf junipers, Picea Balsamica Hudsonica, Cistus Norbury Gem, Campanula garganica and Geum Robertsonii. Ceanothus dentata was lovely, growing in bush-form against the walls of the house.

All the main parts of these gardens are watered by an overhead system of perforated pipes, cunningly fixed in the shrubberies and, being painted dark green, are not openly noticeable. Inadequate as these notes are in doing justice to the many charms of this garden by the sea, they would be still more so if they did not include a reference to the spacious and well stocked aviary, and the wild bird sanctuary, which is a rhododendron, shrub and tree-covered corner, truly representing a portion of natural woodland.

It is, briefly, a restful garden, and our thanks are due to Lady Wavertree for so kindly explaining its many attractive features.

THE AMATEUR SHOW

IN THIS ARTICLE MANY USEFUL HINTS ARE GIVEN TO INTENDING EXHIBITORS.

WOULD-BE exhibitors of hardy plants at the coming amateur show had some assistance from nature by the wet weather of May, which gave plants a good start. Plants generally were then rather backward, but the warm weather experienced in June, up to the time of writing, has brought things along rapidly, and the majority of subjects may now be considered to be in an average state of development for the time of year.

To those who intend exhibiting in the rose classes, work of primary importance a few days before the show will be that of shading the blooms of varieties of warm shades and tones of colour, such as flame and apricot, many crimsons, too, are apt to lose richness of colour and attain the undesirable purplish tint during hot sunshine. The shading must not, however, be dense or more harm than good will be the result. No part of the plant except the bloom must be shaded.

In the tea and hybrid tea rose classes, unless blooms are very plentiful, it will be necessary to try to hold back those which, if left to themselves, may be too forward by the date of the show. This is done by tying the blooms, to prevent premature opening, with the aid of a soft material, such as budding cotton. The time to do this is immediately the first row of petals have expanded. This must be done in such a way as to allow the bud to expand. The easiest method is to give the first knot a double twist, and no further knotting is necessary. This tying will help to retard the opening of the blooms and keep them clean.

Roses for the rambler classes should be chosen, if possible, from the double varieties, as they travel and last, when cut, better than singles. Long stalks, with good sprays and clean, healthy foliage should be chosen. These must be gone over and any old blooms removed, also those with discoloured stamens.

PACKING AND TRAVELLING.

Undoubtedly the best means of taking cut flowers to shows is in water. The small amateur will not, perhaps, be able to do this. It is the method usually adopted by the big exhibitor, whether amateur or trade grower. For this purpose deep boxes or skeleton boxes, with clean canvas sides and top are used. Holed bottoms, into which tins or tubes can be fixed, will be necessary.

For packing dry, flat boxes, such as are used for packing flowers for market, will be ideal. The length and depth of box will be governed by the subjects to be packed. These range from 18ins. to 6ft. in length, and 4ins. to 8ins. in depth. The depth allows for one layer only.

CUTTING.

The best time for cutting outdoor blooms of any kind, during hot weather, is at break of day. The blooms will by this time have had a chance to recover from the effects of the previous day's sun. This early cutting may not, however, be possible and often has to be done the evening before, or even the morning preceding the day of the show. Whenever the cutting is done, receptacles filled with water must be in readiness and the stems placed in immediately. As roses have to be shown in vases, they should be cut with long stems. Avoid cutting into two year old wood as this may cause early fading. One or two hours should be the minimum time for stems to be in water previous to packing in boxes. The blooms will be better kept in a fairly light and airy room free from sun, rather than in a close, dark room.

In choosing show blooms, quality should be observed throughout. It may be taken for granted that freshness, size of bloom, according to variety, colour, healthy foliage, length of spike in certain kinds and uniformity in each vase will be telling points. Sweet peas should have quality and substance, with four flowers well placed on a 12in. to 15in. stalk. A good delphinium should have a spike which scarcely varies in size from top to bottom; the individual flowers large, closely placed, yet not crowding each other, and completely hiding the central stem. In gladioli the first blooms at the base of the spike should be fresh with as many expanded blooms as possible. This also applies to antirrhinums, and is preferable to having to remove lower faded blooms. Carnation blooms should be as large as possible for the variety, with an unburst calyx, long wiry stems and perfect foliage.

PACKING

All flowers should be packed dry, not damped, as is sometimes done. The boxes must be well lined with clean tissue paper. Sticks the exact width of the inside of box, wrapped round with soft paper, must be prepared. These are for the purpose of tightly keeping each layer of blooms in position. It will be necessary to place one in the bottom to support the first layer. In the case of such as roses and carnations, the stick should be placed so that it comes immediately at the base of blooms. When the first layer has been placed in position, the stems are held down tightly by another wrapped stick, and in such a way as to form a bearing for the next layer, and so on, till the box is filled.

Somewhat different arrangements have to be made to support such as delphiniums, antirrhinums and gladioli. For the former, long boxes will be essential, as the stalks must not be shortened. Sticks should be placed in the packing boxes about 3ins. from the bottom and kept in position by tacking or nailing from the outside. The stems are carefully laid on these and tied in several places, three at least, top, bottom and centre.

The tops of certain flowers, such as delphiniums and antirrhinums, have a habit of curling upwards when packed. The tying near the top will probably prevent this. Another means of prevention is to arrange, by labelling, etc., for the boxes to travel end up. If several cases are tied together, this can be easily arranged. It seriously detracts from the appearance of an exhibit if the flowers have the tops curled or bent.

WIRING.

It may be an advantage to do a certain amount of wiring before packing. This would help to straighten out any kink in the stem and prevent others during transit. No mention is made in the schedule about wiring, so that it can be taken as permissible to stage wired blooms. This, however, should only be done if absolutely necessary. A natural arrangement should be aimed at and wired blooms will, no doubt, be noticed by the judges as not being in the best taste.

ARRANGEMENT.

Immediately on arrival at the R.H.S. Hall, positions should be ascertained, vases procured and filled with water, the flowers unpacked and placed in the vases temporarily, to allow them to recover.

In most cases, before finally arranging, it will be necessary partly to fill the vases with some foliage or stems, such as rushes. This must not show above the mouth of the vase. The object of this is to enable the blooms to be arranged and kept in position.

Twelve sprays of sweet peas will make a nice vase without crowding. A few pieces of good, healthy foliage may be allowed to hang over and partly hide the vase. A few tastefully disposed growths should be arranged with the flowers, but not in such a way as to hide any.

For the delphinium and gladiolus which have to be arranged three in a vase, a triangular arrangement is the only one to show off each spike properly, and more will depend on the quality of flowers than the way they are set up.

POT PLANTS.

The packing of begonias, gloxinias and orchids will require much care. For these somewhat special attention will be necessary.

For the majority it will suffice to stake securely according to the kind of plant and to insert three or four stakes around the edge of pot long enough to stand well above the plant when tied up. The foliage and flowers are then carefully tied to the stakes and the whole wrapped round with soft paper.

See that the plants are well watered before packing and that all pots are washed clean. Plenty of good packing material should be used and the plants and pots so tightly packed that there will be no danger of their shaking about in transit.

Strong boxes should be used, but not so large and heavy, but what two men can comfortably move them about. Strong handles should also be provided. ARTHUR J. COBB.

WEAPONS OF GARDEN WARFARE

INSECTICIDES FOR THE SUMMER OFFENSIVE.

GENTLE and peaceful is the art and craft of gardening; nevertheless, it were folly to disguise or to ignore the fact that there is no peace in a garden where there is no warfare against the enemies of plant life.

Season by season the prospect changes, and the enemy of to-day and to-morrow demands other materials and other methods of application than those of yesterday, and the importance of prompt activity at the dawn of summer is the greater by reason of the rapid movement and incessant industry of the varied pests of the summer months.

There is something rather formidable about a tabulated list of insect and fungoid pests which may invade the garden, the orchard and the greenhouse, and sometimes methinks too much stress upon the numbers and variety of destructive pests the gardener may have to contend with and too elaborate instructions regarding preparation of chemical and other mixtures tend to convey the impression that gardening is more of an anxiety and weariness of the flesh than an agreeable pastime or beneficent occupation.

No good purpose would be served by attempting to minimise the folly of neglecting to combat the enemies of plants, but it may certainly be urged

Digitized by Google

that successful warfare is brought well within reach of every garden owner, for both insecticides and fungicides are very plentifully offered by firms who are equipped for faultless manufacture of most reliable fluids and powders which require no more preparation than dilution with water.

Apart from the quite common and easily conquered pests, such as green fly and caterpillars, and the ordinary rusts and mildews, a garden seldom has an extensive range of other foes, so it is by no means always essential to keep an elaborate chemical chest, the wiser plan being to make a point of having a good general purposes insecticide and something sulphurous for common leaf diseases. When some strange and unknown enemy makes its appearance, it is unwise simply to try this or that and await results, for the great need is to suppress both insects and diseases at the earliest opportunity, and the first step should be to learn the identity of the foe, for that will help in deciding what will best cope with it. A particular pest may habitually infest one garden, while it remains practically unknown in another. One season will bring a great plague of an insect, while another is free or has quite a different intruder, but the "Service for Readers" scheme of THE GARDEN affords the opportunity for every reader to ascertain what pest is worrying his plants and what will worry the pest.

There are many insects which pierce the epidermis or skin of a leaf and suck the sap from the cells underneath. A poisonous insecticide which simply coats the surface of the foliage is unlikely to prove effectively destructive of such insects, and resort has to be had to preparations which kill by contact. There are, of course, many substances which are of a caustic nature which would kill the majority of soft-bodied insects, but in so doing they would also damage and frequently destroy soft foliage and young growing shoots, and cannot on that account be used on plants in full activity. Fortunately, however, cold fluids of an adhesive nature which will spread over the hides of insects, creating a gelatinous film, prove fatal, while, practically speaking, harmless to the plants. In some cases the fluid dries, and ensheaths the insect in a hardened shroud which hampers movement, while in others the greasy or sticky film seals up the pores and respiratory organs of the insect and suffocates it.

Among insecticides of this type saponaceous sprays occupy an important place. The old, well tried Gishurst Compound made by Price's Patent Candle Company, Limited; the equally well known and reliable "Abol" made by Abol, Limited, Paddock Wood, Kent; McDougall's Katakilla, made by Messrs. McDougall and Robertson, Limited, formerly of Manchester, now of Berkhamstead; "Kilzall," of the Stonehouse Works Company, West Bromwich; V2 Fluid, the summer wash of Messrs. W. Cooper and Nephews, Berkhamstead, are a few of the leading proprietary insecticides of the "contact" character which may be used for all the sucking insects, and also for caterpillars.

For the latter, and also for weevils, bugs and a host of biting, gnawing and chewing insects it is of great advantage to use a spray which is either poisonous or acrid, and that is where nicotine and also quassia prove to be extremely serviceable.

The nicotine washes of the horticultural sundriesmen are carefully compounded, under the direction of skilled chemists with up-to-date laboratories for determining strength, purity and general efficiency. Messrs. Corry and Co., Bedford Chambers, Covent Garden, London; G. H. Richards, Limited, Borough High Street, S.E.; J. D. Campbell, Lund Street, Cornbrook, Manchester; J. Bentley, Limited, Barrow-on-Humber, Hull; Darlington and Son, Limited, Hackney, London; Robinson Brothers, Limited, West Bromwich; Edward Cook and Co., Limited, Bow, London, E., all make a feature of nicotine washes, and although nicotine is an expensive commodity, it is extremely economical in use because highly powerful; while for fumigating greenhouses XL All Vaporizer, McDougall's sheets and cones, Abol Fumigating Shreds, Darlington's Auto-Shreds, Corry's "Lethorion" Fumigators, Bull's Shreds, the Briton Ferry Chemical and Manure Company, Limited's Auto-Shreds and several other proprietary articles of a similar nature are among the greatest boons to gardeners, and the most dreaded terrors of the insect world.

One might extend references to insecticides to great extent, but the Garden Supplies, Limited, Cranmer Street, Liverpool; Messrs. Murphy and Son, Limited, Mortlake; Messrs. T. Vickers and Sons, Limited, Wigan; The Chemical Union, Limited, Ipswich; and the Strawson Chemical Company, Limited, 79, Queen Victoria Street, E.C., are a few firms to whom horticulture is indebted for cleverly prescribed death-dealing weapons of gardening warfare, and even that troublesome and tenacious pest of tomatoes, salvias and many other plants, white fly, can be worried out of existence by careful use of one or other of the advertised white fly antidotes. A. J. MACSELF.

CORRESPONDENCE

VIBURNUMS CARLESII AND BITCHIUENSE.

SIR,—As a friend of both your correspondents, may I venture to suggest that the difference of opinion between Sir H. Maxwell and Mr. F. Stern as to the merits of Viburnum Carlesii and V. bitchiuense (not bitchuenense) has its origin in the fact that the specimens of the latter at Monreith are obviously not of the best form of a variable plant? Were it otherwise, the flower buds of the plants there would certainly have that engaging rose tint which Mr. Stern—and others—find so attractive, and Sir Herbert Maxwell does not detect.

This viburnum grows wild on the mountains of Bitchiu, a province of western Japan, and was named by the Japanese botanist, Makino, in 1902. It is often said to be inferior to V. Carlesii, with which at one time it was confused by importers, who sent it here in moderate quantities; and so as a small plant, it usually is. But a comparison of two plants of such different habit is hardly fair. There are specimens of V. bitchiuense in this country as much as 10ft. high, of free branching habit, and when the fragrant, rose-tinted flower buds open in spring among the bronzing leaves, he would be a bold man who would pronounce it an inferior to Carles' species, so persistently miscalled Carlesii. It has the great advantage over the latter of rapid growth, and, like V. fragrans and Osmanthus Delavayi. has evidently not reached its maximum yet in Britain.

Sir Herbert Maxwell expresses the view that V. Carlesii is the choicest of the deciduous species, and his opinion is entitled to every respect. But even doctors differ, and there are good judges who prefer V. fragrans—for more reasons than one.—A. GROVE.

A PRONOUNCING DICTIONARY.

SIR,—In your issue of May 16th, a correspondent, C. F. Gray, writes about the pronunciation of botanical Latin and advocates a small dictionary being compiled. As a matter of fact, in 1909 the *Gardeners' Chronicle* published a little book for 1s., called "Pronunciation of Plant Names." It is very simple, and, I believe, correct, except for making "erica" with the "i" long; as it is derived from *ericius*, a hedgehog, it should certainly be short.—C. G. O. BOND.

FRAGRANCE IN THE GARDEN.

SIR,—The article on "Fragrance in the Garden," by Mr. H. W. Canning-Wright, published in THE GARDEN, February 28th, 1925, is exceedingly interesting, and deserves the attention of all raisers of new varieties of plants. My few observations for some years past on the fragrance of plants clearly show that such plants as roses and sweet peas—that is, most of the new or modern varieties—are greatly wanting in that delicious perfume for which older varieties were famous. We have in many of our Australian plants, delicious fragrance—quite different from the many odours of European, Asiatic and American plants—such as some species of boronias, acacias, species of epacrids, eucalypts and many others needless to refer to here. My object in writing is to refer to a plant, Cestrum nocturnum, which, I think, should grow very well in warm, sheltered places in Great Britain. It bears profusely tube-shaped, long, yellowish green flowers which at nights emit wonderful and delicious fragrance, something like that of the well known night-scented stock, but infinitely better and more profuse. The plant is a dense-growing shrub which attains a height of about 10ft. or so, and succeeds well in almost any kind of fairly well drained soil. About the suburbs of Sydney it succeeds admirably with little or no care.

I may add that one or two species of xerotes—common about the suburbs of Sydney and which grows about sandstone rocks—the foliage of which resembles somewhat that of Iris stylosa, have very peculiar fragrance. In the old days of the colony the colloquial name was "Rum-bottles," for want of a better I suppose.

I have been a subscriber to THE GARDEN for more than fifty years, and have a great regard for the good old publication.—WALTER S. CAMPBELL, *Sydney, New South Wales.*

THE FLORAL DISPLAY AT YORK GALA

IDEAL weather favoured this interesting northern event. Cloudy skies and a cool, northerly breeze following the recent heat wave must have made the heart of the exhibitor glad. It was also more comfortable from the visitors' standpoint, for the marquees were never overpowering and oppressive and the exhibits remained in good condition.

There were two large tents filled to their utmost limits with the choicest productions of the country's nurseries and gardens, and well known growers from far and near had spared no expense to bring of their best. The crowds that filed past the stands in a continuous stream proved that interest in all branches of horticulture is very strong in the north and the public patronage must have set at rest all doubts as to the future success of the Gala.

THE ROCK GARDENS.

These were a special feature, and foremost among them was a splendid exhibit by Messrs. James Backhouse Nurseries, Limited (York). The chief point in this striking erection was an extra fine waterfall. The rockwork was composed of water-worn mountain limestone. Very attractive were the Japanese maples and various deciduous trees, among them being the golden oak and Persian plum. There was a mound of heather and silver birch in the centre. A good collection of dwarf rock conifers and fine banks of kalmias and rhododendrons, together with groups of rock roses in various colours were prominent. Silver funkia was placed along the water's edge. Primula Bulleyana and Beesian hybrids were in excellent condition. There was a fine background of spruce and evergreens. A large gold medal was awarded for this exhibit.

Mr. Pickering, a local specialist in rockwork, won two first prizes, one for a charming rock and water garden and the other for a water garden. In the former there was a waterfall, with a background of Japanese maple and copper beech. Campanulas, lychnis, sedums, rock roses, thrift and primulas were well grown and tastefully arranged. Mimulus, irises, thrift, rhododendrons and the Chinese buttercup were chiefly used in the water garden.

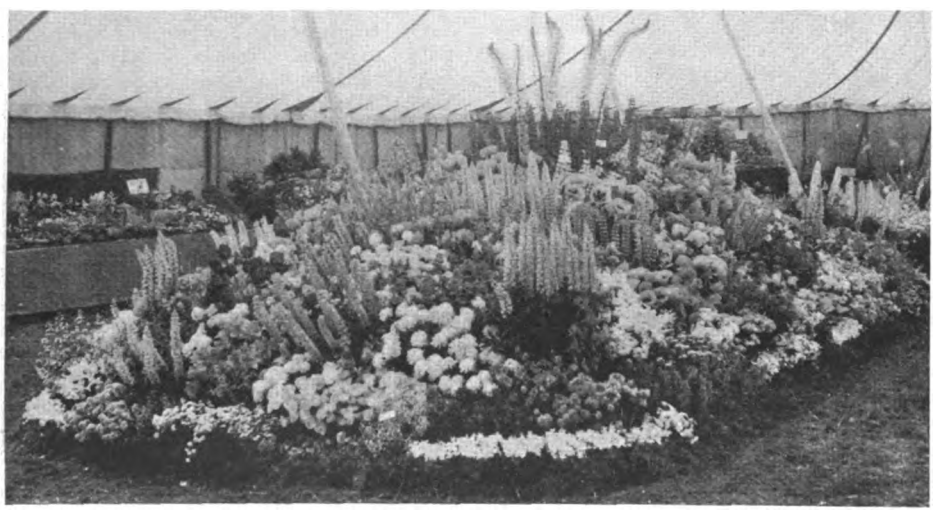
Messrs. Wilson and Agar had a very pretty formal garden, with a paved terrace and two flights of steps. There was a semi-circular pool leading to a fountain and at the back of the exhibit an original gargoyle in the form of a frog in lead on a raised wall. The chief feature in the setting was a neat arrangement of Iris Lord of June, lupins, delphiniums and a number of uncommon alpines. A low wall surrounded the whole garden and there was a foil of fine specimen box.

Mr. P. Gardener had an excellent water garden in which were many choice primulas and a fine lot of Iris Lord of June. It was banked with shrubs, Japanese maples and conifers. His rock garden was built with waterworn limestone and planted with choice varieties of thrift, dianthus, heuchera, brooms and aquilegia.

Other notable rock exhibits were those of Messrs. Maxwell and Beale, and a local exhibitor, Mr. J. H. Winn.

HERBACEOUS EXHIBITS.

These occupied the same marquee as the rock gardens. They were large and comprehensive and contained the choicest seasonable varieties. Messrs. Harkness and Sons, whose exhibit we illustrate, won first prize, and in this fine display lupins were a prominent feature. Messrs. Gibson also had a choice selection of plants in great variety, and Messrs. Longster's exhibit was not far behind. These three firms are regular exhibitors at the show.



THE FINE EXHIBIT OF HERBACEOUS PLANTS STAGED BY MESSRS. HARKNESS.

On many other stands, notably those of Mr. J. D. Hutchinson, Kirbymoorside; Mr. G. A. Millar, Messrs. M. Prichard and Sons, Messrs. Baker's and Messrs. Toogood's, herbaceous plants were to be found in fine condition.

ROSES.

There has never before been such a fine display of roses at York. There were so many that an overflow tent had to be provided. Messrs. Alex. Dickson and Sons, Limited, showed several new varieties, one of the best of which was Simon, a dazzling red decorative rose. It is more than semi-double, very free flowering, and we understand that it has an ideal bedding habit. Duchess of York, previously shown as Moyna MacGill, is a striking bicolor, and Dame Edith Helen is very sweetly scented, deep rose pink in colour and one of the best for all purposes. On this stand the popular varieties, such as Betty Uprichard, Lady Inchiquin, Los Angeles, Mrs. Herbert Stevens and Golden Emblem were well shown, and the 1925 novelties, Scarlet Glory, a free flowering decorative rose that may be described as a scarlet Donald McDonald; Barbara Robinson, deeper and richer than Clarice Goodacre, with all the latter's good qualities; Climbing Sunstar, which has the real climbing habit; and Saltaire, a deep crimson with strong growth.

Mr. Elisha Hicks had some very fine specimens in his prize-winning stands, and his best varieties were Ophelia, Clovelly, Mrs. H. Winnett, more pleasing in colour than one usually sees it, and Mrs. Herbert Stevens, which he invariably grows well.

Mr. Prince had a very fine collection and Allan Chandler was particularly well shown. This is a splendid pillar rose, rich in colour, which does not fade. There was also an interesting group of Rosa hemisphærica, a lovely yellow rose, on this stand.

SWEET PEAS.

Nothing finer in sweet peas could be wished than the gorgeous displays of bloom set up by Messrs. Robert Bolton and Son, Messrs. Dobbie and Co., Messrs. Alex. Dickson and Sons, and Mr. Henry Eckford. All the popular varieties were in profusion and also many notable novelties.

Messrs. Bolton and Son received a large gold medal for their huge display in which Gold Crest, Black Bess, Peggy, Royal Pink, Wizard, Picture, Ivory Picture, Matchless, Wembley and many others were admirably staged. The first three varieties were awarded a certificate of merit.

Messrs. Dobbie and Co. had Miss California, Powerscourt, Royal Sovereign, Youth, Ruby, Mary Pickford, Grenadier and Royal Purple in fine condition.

Messrs. Dickson's four novelties, Magnet, Crusader, Dainty Maid and Mermaid, were well shown, along with many other varieties.

Mr. Eckford had some well grown exhibition flowers in many popular shades and his new ones were Mrs. John Curwen and Betty.

CARNATIONS AND PINKS.

Mr. Engelmann had a wonderful display of carnations, and his new variety, Red Laddie, received a certificate of merit. Other new kinds were Dainty and Corola Striata, a striped form of Carola. In this exhibit White Pearl, Topsy, Peerless, Delice, Laddie, White Enchantress, Saffron, Maine Sunshine and Tarzan were all in excellent condition.

Mr C. H. Herbert had a neat stand of his famous pinks, among which were good vases of Bridesmaid, Model, Mrs. Giffard Woolley, Mrs. G. Walker and Queen Mary. Fire King, a dazzling orange scarlet, was also noticeable on this stand.

ANTIRRHINUMS.

Messrs. Sutton and Sons had a magnificent stand of antirrhinums, among which we noticed Giant Yellow, Eclipse and Lilac Queen in tall kinds, and Orange King, Buff Beauty and Canary Yellow, in the intermediate section.

Messrs. W. H. Simpson and Sons also had fine antirrhinums and these included good specimens of Lady Roberts, Empress, Golden Gem, Appleby Matthews and Sybil Eckford.

OTHER EXHIBITS.

The orchids, as usual, were outstanding, and the leading firms had their choicest varieties in excellent condition. Violas were well shown by Mr. Arthur H. Todd and Mr. R. V. Roger. Very interesting was the display of fruit by Messrs. Chas. E. Simpson and Sons, as were also Messrs. Rivers' fruit trees in pots. Messrs. Lowe and Gibson had some fine delphiniums grown from seed of their noted "British Birds" strain. On the stand of Messrs. Storrie and Storrie there were some very interesting subjects, the best being Begonia Narcissiflora, with a narcissus-like trumpet, croton-leaved coleus, and some fine aquilegia. The latter were also very well shown by Mr. V. C. Vickers, who exhibited an interesting new raspberry named The Viking.

SIMPLE GARDENING

CALCEOLARIAS AND CINERARIAS.

I HAVE recently been much interested in collections of these charming flowers in several parts of the south coast. I think they are very interesting flowers for the amateur, as well as the professional gardener to grow, The colours are so varied and rich and the blossoms come at a season when conservatory flowers are scarce. As a youth I paid many visits to a neighbour, an amateur, who possessed a very old brick frame, which held a great attraction for me. I saw in it some herbaceous calceolaria plants which always appeared nicely covered with moisture, like dew on the grass, and those plants did remarkably well because their surroundings were so suitable. On this experience I acted in after years when I began, seriously, to make gardening my life work, and refer to it here for the benefit of my readers who may not possess much knowledge of these plants and their treatment. The calceolaria thrives in a quite cool position, in fact it needs a cooler one than the cineraria; its roots are finer than those of the latter and yet I have found my best plants result from pottings in quite heavy loams in which only a small quantity of leaf-soil has been mixed. The present is a suitable time for sowing seeds of both kinds of plants. The seeds should be sown in pots or pans, very thinly, the calceolaria seeds being simply pressed into the level surface of the soil after the latter has been watered. Of course, a hot position is bad for both seedlings and plants, and failing such for the garden frame, I would create such a position even if I moved a frame to the north side of a row of peas or runner beans. Full light should reach the seedlings, but not any direct rays from the sun. First transplant the seedlings round the sides of small or 6in. pots and then pot them singly in 3in. ones.

BULBS IN GRASS AND WHEN LIFTED.

There are people who love bulbs in the flower garden, but do not grow them because they interfere with the summer bedding-out arrangements. If the latter is of more importance than the bulbs, then the bulbs are sure to suffer a little, if grown. But there is a right way to treat the bulbs and few cultivators carry out this treatment as it should be. They generally lift the bulbs quite early and "heel" them in in some out of the way border for several weeks, thus exposing them to the influence of the moist soil, which causes new roots to grow prematurely and matters are made worse if rain comes in the meantime. In due time these bulbs are again lifted and re-planted and this work cannot be done without serious destruction of the new, fleshy roots. The better plan is to lift the bulbs as late as possible consistent with the forwarding of the work of bedding-out other kinds of plants. No doubt the great majority of the bulbs are now lifted and many of them are being neglected. Collect every one and place them in boxes or on the floor of some cool shed—an open shed will be the most suitable. Do not forcibly remove the tops nor any soil adhering to the roots. These bulbs are to remain in position till they have gradually and thoroughly dried, when the stems may be removed and the plump, glossy-looking bulbs should be placed in paper bags. The bulbs in pots should be left there till properly ripened, and to ensure this the pots must be placed on their sides in a sunny position all being kept quite dry. The leaves of bulbs grown in grass and woodland should be allowed to wither naturally before any trimming, for the sake of tidiness, is done.

STAKING PLANTS.

It is quite an accomplishment to be able to stake growing plants so that their natural form will not be altered, and, of course, not marred. It does not matter much whether the subjects are border or climbing plants, but if care be needed in dealing with one class more than another, it should be given to the border

plants, as climbers are always persistent in trying to get out of bounds and so faulty tying is not as apparent as in the case, say, of herbaceous plants. Where stakes are used they should be painted dark green and green tying material used, then, if the supports are well placed and the tying is neatly done, the general effect will be pleasing. It is not a question of number of stakes, but of their disposal, as few as possible should be used consistent with efficiency. In some districts stakes are difficult to obtain, in others they are plentiful. We will suppose that they are scarce and only one can be used where three should be. The single stake should be placed at *b*, at the side, or outer edge of a branching plant or clump of them. The raffia or string should be made secure to the stake, passed round the clump and tied near the stake, thus holding all stems loosely, but firmly. The three stakes may be placed as shown at *d*, *d*, *d*; the string placed circle wise all round the clump and, if the latter is massive, through it from stake to stake, as shown at *e*, *e*, *e*. It is wrong to fix a single stake in the centre of a circle *f*, as at *g*, and showing at *h*, tied at *i*, as the result would be unsightly specimens. When staked the clump should look like the one *j*. Tying climbers to rough stakes is easily done if the strings are passed round them about big knots as shown at *k*, *k*, *k*.

HOW TO MANAGE GLASSHOUSES IN SUMMERTIME.

I am induced to include this subject in my collection of notes because I have seen so many glass structures mismanaged year after year. Some are totally neglected; others are not shaded, neither are they properly ventilated, nor the plants in them suitably treated. In the winter time it is pleasant to enter a warm greenhouse; in midsummer it is torture to do so when the sun is shining on a mismanaged one. I need not repeat why it is a torture. If the roof glass and, maybe, a portion of the sides and ends be slightly shaded, either with permanent or temporary shading material, the floor duly damped, the plants watered as they require it and the ventilators manipulated according to the prevailing weather conditions, a visit to the occupants would be just as pleasant on a really hot day as in the depth of winter. Generally, if it is unpleasant for one to be under glass on a hot day, it is equally bad for the plants there. From the end of June to the end of August, night ventilation is beneficial to miscellaneous greenhouse and conservatory plants, and this night airing should be duly increased early in the day in very bright weather. Morning and early evening waterings are best; avoid mid-day ones, because the roots are warm, and pipe, well or cistern water is much colder and would cause a check; but water then rather than allow the plants to suffer, using water that has been placed in vessels in the same house. A mid-day damping of borders, under stages or floors, is highly beneficial to the plants.

GEORGE GARNER.

CORYLOPSIS PAUCIFLORA.

DURING early spring this delightful little shrub was most attractive. It is of somewhat spreading habit, growing about 4ft. high, but the plants I have seen have not exceeded 3ft. The flowers are produced on twiggy, leafless branches, these being practically covered with primrose yellow blooms three-quarters of an inch across. They are usually in pairs, and hang down, so to see them at their best they must be viewed from beneath, which suggests an elevated spot on the rock garden. In the milder parts of the country it will succeed, and should be afforded a position protected from the north-east and east winds. Any good garden soil will suit it. C. pauciflora is allied to hamamelis, but it is not so hardy.

CONSERVATORY AND GREENHOUSE

GILIA CORONOPIFOLIA. — This beautiful biennial is deserving of more general cultivation for furnishing the conservatory, and for this purpose seed should be sown now in a cool greenhouse.

When fit to handle the seedlings should be pricked off singly into thumb pots, affording water carefully until they are well rooted. Their next shift should be into sixty-sized pots, in which size they should be wintered. During the winter they require very careful handling, for, in common with many Californian plants, damp proves fatal to them during our sunless winter months. A shelf well up to the roof glass in a light, airy house is the most suitable position for them, and no more water should be given at the root than what is necessary to keep them from suffering. It is also important that the foliage be kept dry. Early in the year they should be ready for a shift into their flowering pots, which may be 5in. or 6in., according to the strength of the plants. When well established and under improved weather conditions they will take increased supplies of water, but care must always be exercised with this plant.

REHMANNIA ANGULATA.—Where this plant is grown for conservatory decoration seed should be sown this month in a cool greenhouse. When fit to handle, the seedlings should be pricked off singly into small pots, afterwards potting them on as they require it. As this plant is nearly hardy, it may be grown successfully in a cold frame. Well grown examples will require 7in. or 8in. pots for their flowering size. This plant is very useful, as it flowers over a long period; there is also a fine white variety of it.

BRUNFELSIA (FRANCISCEA) CALYCINA and its varieties eximia and macrantha are generally regarded as stove plants, and are treated as such. They, however, succeed perfectly in an ordinary greenhouse during their flowering period, flowering in wonderful profusion for several weeks. B. macrantha is undoubtedly the best one to grow for this purpose. Cuttings root readily in a warm propagating case. Throughout the growing period they are best kept in an intermediate house, while during the winter they should be kept somewhat dry at the root, but must not be allowed to suffer in this respect. This plant has the advantage of flowering early, plants in small sixty pots flowering freely. In two or three years good useful plants for the stages can be obtained. They also have the advantage of being long-lived, for with annual re-potting the same plants may be grown in 6in. or 7in. pots for a number of years. On the other hand, if so desired, they may be grown on to form large specimens. It is also an ideal plant for planting out in a well drained bed or border in a warm greenhouse. B. americana is quite distinct from the other species, having sweet-scented flowers which are yellow when they first open, afterwards changing to white. This plant is worthy of more general cultivation, is easily propagated by means of cuttings, and succeeds under the same treatment indicated for the other species.

SCUTELLARIA COSTARICANA.—Than this plant, with with its scarlet flowers tipped with gold, there are few more brilliant for the decoration of the greenhouse. Cuttings root readily at any time in a warm propagating case. They are best grown in a temperature of 50° to 55°, and as they approach their flowering period should be gradually accustomed to cooler conditions. The young plants should be pinched once or twice to induce them to throw strong shoots from the base, and these should be allowed to run up without stopping. Good examples may be flowered in 5in. or 6in. pots. This plant grows freely in any good potting compost. S. violacea and S. coccinea treated in the same way are also excellent for the greenhouse. They are all subject to attacks of white fly, which must be prevented by fumigation with hydrocyanic acid gas or some other approved remedy.

ISOLOMA HIRSUTUM, which has been in flower for at least two months, is another excellent plant for the greenhouse, and by rooting successional batches may be had in flower all the summer. Cuttings root readily in a warm propagating case, and should be grown on in a temperature of 50° to 55°. To do them justice they should be placed in 6in. pots for flowering. Well grown plants will in time attain a height of 3ft. to 4ft. At this stage they may have a shift into 8in. pots, in which they make fine specimens for standing in beds in the conservatory. If given proper attention this plant will flower for at least six or eight months. J. COUTTS.

LABOUR-SAVING IN THE GARDEN

A USEFUL ATTACHMENT FOR A LIGHT LAWN MOWER.

THERE are now a number of efficient edge trimmers on the market which combine trimming and truing the edge of the lawn, and are a great improvement on the old-fashioned edging knife and long-handled shears. Even with the use of these the last few inches at the edge of the lawn are troublesome to cut if a side wheel lawn mower is used. It has to be done either by hand or else the lawn mower cuts it with one of its wheels partly off the lawn, a state of affairs which is neither good for the edge nor for the mower. A patent attachment is now being sold by a number of firms. It is known as Slatter's Patent Front Runner, and enables a side wheel mower to be used for cutting close up to the edge of a lawn.

SPRAYING ON A SMALL SCALE.

During the early summer months to keep down biting and sucking insects, which attack fruit trees of all kinds, spraying is essential. Aphis particularly become very active, and unless kept in check in the early stages of development, much damage will be done to the plants later on. Regular and timely spraying as preventives rather than cures should be aimed at. An efficient spraying machine suitable for the kind of work and the amount it is required to do should be in readiness at all times. Many amateurs do not wish to buy, and do not need a large knapsack machine. These are unnecessarily heavy, and a smaller make, even though it has to be refilled oftener, is much more convenient for use in a moderate-sized garden or in the amateur's greenhouse. The Vermorel pneumatic hand sprayer is ideal for such a purpose and of great service in every type of spraying. It is light, easy to manipulate and can be obtained in two sizes, The larger is made of brass and the smaller of copper. The capacity of the machines are 3½ and 2½ pints respectively, and they weigh 5½lb. and 2¼lb. When pressure has been established all the contents are expelled in a continuous spray.

A TIME SAVING DEVICE.

Peach disbudding, nailing up young shoots of wall fruit and countless other odd jobs in fruit culture which mean a cut here or a tie there are tasks which take up a considerable time. Only a small area can be reached when the ladder is in one position, and to attend to the lower portions of the trees a shorter ladder has to be used. Being obliged to use a different type of ladder for the lower branches and the constant moving which is necessary involve the loss of a certain amount of time. And, again, a ladder which is suitable for resting against a wall cannot be used, for instance, in the pruning of the top of the branches of bush apples. For this a step ladder is necessary. A most convenient ladder which combines both types is known as the Handy 2 in 1 Ladder, and it certainly is a very useful and time-saving invention, to say nothing of the money saved by being able to make one ladder do the work of two. This ladder is hinged in the middle, the top half bending over and forming a step ladder. As it thus has steps on each side when in the step ladder position, a larger portion of the tree can be reached before moving again. The hinge is made of heavy unbreakable steel, and automatically locks itself in both positions and is absolutely secure. When the ladder is used as a pair of steps the top step is extra wide and can be used for standing a bucket on. There are many times when such a ladder will be useful—in the vinery, for pruning, for training wall fruit and for reaching the shelves in the greenhouse are only a few instances.

THE GARDEN

VOL. LXXXIX.—No. 2798. JULY 4, 1925

Price Threepence. Yearly Subscription, Inland, 17s. 4d.; Foreign, 17s. 4d. Registered at the General Post Office as a Newspaper and for Canadian Magazine Post.

Editorial Offices: 20, TAVISTOCK STREET, COVENT GARDEN, W.C.2. *Offices for Advertisements:* 6–11, SOUTHAMPTON STREET, STRAND, W.C.2.

Entered as Second-class Matter at the New York, N.Y., Post Office.

IN ALL GARDENS, BE THEY EVER SO SMALL, A CORNER SHOULD BE FOUND FOR THE OLD FASHIONED SWEET SMELLING SHRUBS AND FLOWERS. BUSHES OF ROSEMARY AND LAVENDER WITH THEIR TIME HONOURED CHARMS, DRIFTS OF CLIMBING ROSES IN THEIR FULL SUMMER GRANDEUR, WITH STATELY SOMBRE IRISH YEWS AS SOLEMN SENTINELS, MAKE AN ENCHANTING SETTING FOR ANY WILD GARDEN.

Digitized by Google

The ROCK GARDEN in EARLY SUMMER

WITH A LITTLE CARE AND ATTENTION DEVOTED TO THE INMATES OF THE ROCK GARDEN IN THE EARLIER MONTHS OF THE YEAR, THE RESULTS ACHIEVED IN THE SUMMER SEASON IN THE SHAPE OF A WEALTH OF COLOUR AND BLOOM ARE TRULY ASTONISHING.

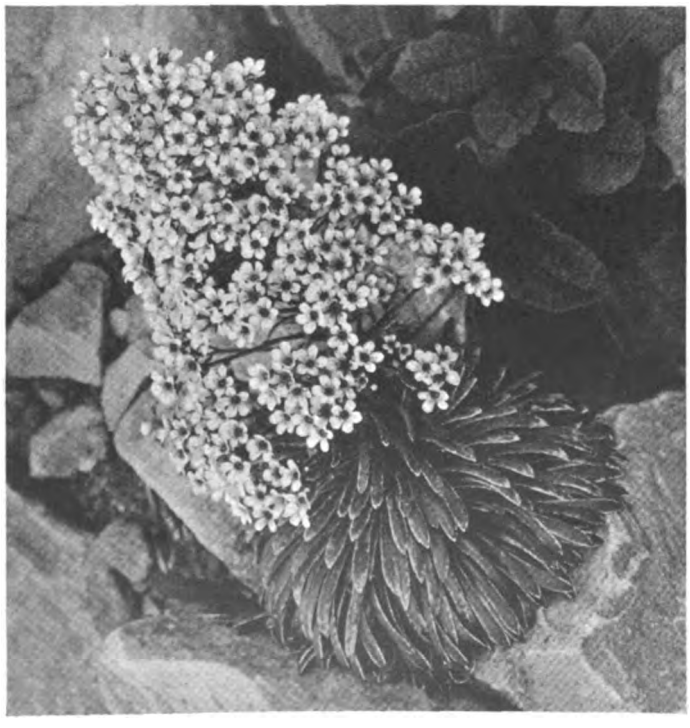
THOUGH the roots of twitch and bindweed may defy all efforts at extraction, twisting and twining to an unbelievable length beneath the stones you least wish to move, the personal cultivation of a rock garden brings with it a wonderful feeling of creative satisfaction, and memories of long past expeditions to the enchanting mountains of Norway. Switzerland and Austria, each tiny plant seeming to smile at you in recognition of the thought and care bestowed upon it,

The frequent thunderstorms during the recent heat wave have kept the rock garden well moistened, and those alpine gardeners who delayed until the beginning of April to fill in the crevices left bare by the ravages of the wet winter have been well rewarded. Plants such as Soldanella minima or alpina, Androsace carnea and Saxifraga oppositifolia turned out of their pots well rooted, have suffered no check to their growth, and now flourish exceedingly.

The cool northern slopes are clothed with the green carpet of Arenaria balearica, with its myriads of tiny white flowers on slender stems not more than 1in. high; while nothing could be of a purer white than the large bell-like flowers of A. montana. All the varieties of low-growing phlox are now at their best, palest pink, lavender, and white, and grow satisfactorily if in an open place where they are not tempted to straggle about for light and air. They seem rather to enjoy being compressed between small rocks or large stones, and grow in more compact, pleasing masses. One of the most beautiful is Phlox nivalis, but this will have suffered in most gardens from the damp mild winter, so that cuttings should be taken whenever possible, as it does not seed freely.

The mossy saxifrages are past their best, but where they are not dried and over-heated they remain a glory even into June. Perhaps the best is S. muscoides, and its variety atropurpurea. At the present time they press closely against their surrounding stones, throwing up innumerable short stems with little pink blossoms, very neat and easily grown. When the flowers die off, the plants do not straggle about and become untidy as do most "mossies," but the closely packed foliage turns at the approach of autumn to a pleasing crimson and sober green.

The same pleasure may be obtained from the foliage of S. Rhei, and its variety Guildford Seedling, no less than from their flowers, both of which keep their colour better when not in full sun. S. Wallacei, on the other hand, cannot boast of this neatness of growth, but repays any trouble a gardener may take in rearing new plants. It grows rapidly and is apt to become ragged, dying off in the centre; but plants of not more than two or three years' growth are now of great beauty in the rock garden, transforming their corners into sheets of dazzling white with really large well opened flowers.



SAXIFRAGA LONGIFOLIA, FROM THE PYRENEES, THE FINEST OF THE ENCRUSTED SAXIFRAGES.

DURING THIS MONTH THE SUN ROSES, OR HELIANTHEMUMS, ARE AMONG THE MOST BEAUTIFUL PLANTS IN THE ROCK GARDEN.

Of more interest, undoubtedly, are the encrusted saxifrages, so called from the fact that the pores on the leaves are encrusted by the chalk, taken in through the roots, crystallising and blocking the opening, thus preventing excessive evaporation during hot sunny weather, as the plants live on dry stony heights.

The best of all these is Saxifraga longifolia from the Pyrenees, which grows well when planted in a tight crevice with plenty of limestone chips and mortar rubble in the loam, and with a deep root run. It never sends out offshoots, but grows readily from seed planted either in autumn or spring, and will not flower during its first twelve months. When

Digitized by Google

the plant is mature, however, and the long, whitish green outer leaves are spread out like a star, it will throw up from its closely packed centre a pyramid of blossom, a hundred or more pure white flowers, borne on a stem from 1ft. to 1½ft. high, most beautiful and uncommon in form. The seeds should be collected daily, as those from the lower flowers ripen first and fall before the higher seed vessels have matured.

SS. lingulata, crustata and Aizoon are all valuable and of great beauty at the end of May and in June. Though they are of looser growth, and the flower heads shorter and less densely packed with flowers, they creep round the stones in a most dainty way when well established. Some brought back from the Riffel Alp in 1908 are now quite naturalised. They have seeded about in the chinks of rock, and everywhere have spread into masses of silver or grey-blue stars, the smaller nestling among the more mature, which throw up spikes of white flowers of a loose but graceful growth, the stems of S. lingulata being of an attractive reddish colour from about 10ins. to 1ft. high.

SAXIFRAGA WALLACEI IN SHEETS OF DAZZLING WHITE ALONG WITH ANEMONE BALDENSIS.

S. rotundifolia is another rockfoil which has spread and increased since it was brought back in 1908 from the Riffel Alp. Planted in the cool damp corners of the rock garden it throws up innumerable pink-spotted small flowers, as in the sub-alpine woodlands. There are some tiny varieties growing after the manner of the robust London Pride, each small tuft giving off a head of pale pink, fragile flowers; these easily increase and fill steep crevices.

All the varieties of sempervivum, too, are now at their best, from S. Tectorum, the common houseleek, native in the great mountain ranges of Europe, to the cobweb S. arachnoideum, that attractive plant that looks as though it employed a troop of spiders to bind together its fleshy, succulent leaves in a meshwork of fine white threads. Apparently this is a provision of nature to hold the leaves more erect, and so to ensure that the sunlight should fall obliquely on the upturned surfaces; thus, excessive evaporation is checked when the plants live in arid rocky heights. Just as the encrustation of the silver saxifrages becomes less when moisture is plentiful, so the cobwebbing of S. arachnoideum diminishes if it grows in a cooler, damper situation. This species, like S. montanum, has picturesque rose-coloured flowers, while those of Wulfeni and Gaudini are yellow. They make a beautiful decoration in shallow pans of grit, chips and sandy loam, but if grown in the rock garden their methods of finding fresh ground over the bare face of small rocks, when their own niche has become overcrowded, is of great interest. So long as there is room surrounding the original rosette, the runners sent out produce a fresh rosette and root immediately around the parent; but later, when the dense mass of rosettes can no longer expand for lack of root room, the runners grow longer and longer till they reach a fresh crevice over the rock face; thus a well naturalised colony appears to be handing its children across the face of the precipice, with human care for the preservation of its offspring.

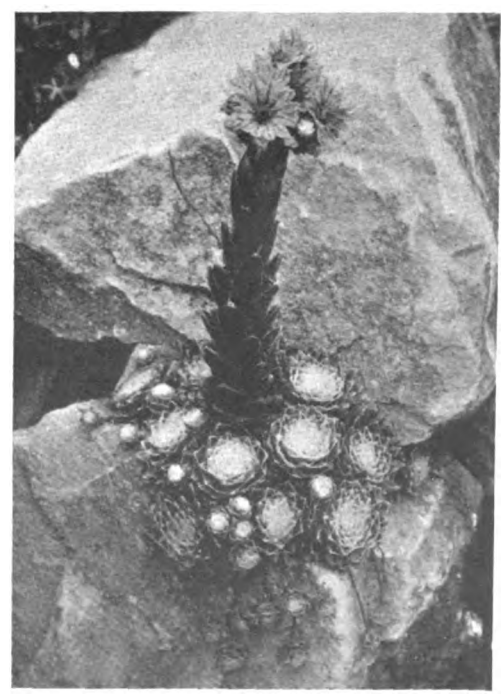
Many of the silenes, helianthemums, daphnes, androsaces, and geums are now in full flower; and our native beauty of the limestone rocks of Scotland, Dryas octopetala, must not be forgotten. Then the Gentians, acaulis and verna, together with the vivid blue of Lithospermum prostratum, make a remarkable blaze of colour if they have condescended to thrive. Deep moisture, perfect drainage, exposure to sun and air, protection from devastating winds, deep loam with sand grit and leaf-mould, a good top-dressing when the flowers are over—and in the case of the gentians cut from their stock, all these are demanded—and such attentions are, as a rule, repaid by a glory of surpassing loveliness.

Lightness and variety are produced by allowing the white Anemone alpina to seed itself where it will in the rock garden, and if A. baldensis and A. narcissiflora can be persuaded to do the same, the result is as perfect as can be obtained. It is of enormous advantage to back the rock garden with a few tall plants, such as aquilegias, iris, white foxgloves, yuccas, Martagon and St. Bruno's lilies, with the alluring spikes of the various species of eremurus. These thrive and readily increase where they are happy, and give distinction and pleasure by their 10ft. spikes of pink buds, opening from below into fascinating, long-anthered, pale pink flowers, each petal centred by a deep ridge of darker pink, and each characteristically pressed backwards as if to show its full glory.

Thus, by a judicious selection of plants, the rock garden can be made a perfect joy in June and July.

CHRISTINA MARSH.

THE COMMON HOUSELEEK, SEMPERVIVUM TECTORUM.



SEMPERVIVUM ARACHNOIDEUM WITH ITS CHARACTERISTIC WHITE COBWEB.

THE ROBERTSONIAN SAXIFRAGES

BY DR. R. LLOYD PRAEGER.

THE well known London Pride group of saxifrages consists of just three species, all common in cultivation—the kidney-leaved saxifrage (S. Geum), the London Pride (S. umbrosa), and S. cuneifolia, which has not a recognised English name. Haworth (1812) placed them in a separate genus, which he called Robertsonia; Tausch (1823) named them hydatica, and Don (1822), gymnopera; but all subsequent botanists follow Linnæus (1737), in including them in the great genus saxifraga. All three are confined to central or western Europe, where they have very distinct ranges, S. cuneifolia being abundant in the Alps and surrounding regions and extending to the Pyrenees, while S. umbrosa and S. Geum are confined to the Pyrenean region and Ireland. As regards the last two species, much confusion has long existed, in two respects. Firstly, as to their distribution; both easily run wild, and having been for a long time in cultivation throughout the greater part of Europe, they have often been recorded as native, where they are only naturalised. I suspect that all the records from central Europe—Germany, Switzerland, Austria—belong to this category (though Austrian botanists consider S. umbrosa native in ravines near Ternberg); certainly the records from England, Scotland and northern Ireland are inadmissible. Secondly, all three species are variable, and, moreover, S. umbrosa and S. Geum hybridise freely where they grow together. Quite a number of these varieties or hybrids have, at different times, been described as species—for instance, SS. dentata, crenata, modesta, hirsuta, Donii, sphæroidea, polita, elegans, gracilis, serrata, serratifolia, spathularis. There are, in addition, a number of garden varietal names, mostly of little value, many of which will be found mentioned in Farrer's "English Rock Garden."

Since two of the species occupy regions remote from most European botanists, it is not a matter of surprise that the majority of the botanical books make rather a hash of this difficult group; but one might have hoped that in the great monograph on Saxifraga, by Engler and Irmscher, published in the Pflanzenreich series in 1919, we should have had all this confusion swept away, and a clear account given of the species and their complicated offspring. That is, however, still a desideratum. The authors named divide S. Geum into two subspecies, eleven varieties, and five forms, and S. umbrosa into three varieties and four forms; plants known only in gardens being included. But a large number of these variants are, without question, hybrids, and others are not more distinct—sometimes less so—than other varieties, both wild and cultivated, which are not mentioned—for instance, the dainty primuloides form of S. umbrosa, the loveliest of all the London Prides. If one goes, say, to County Kerry, where umbrosa and Geum grow abundantly, one receives an education in this group that is most enlightening. I have had no opportunity of studying the plants in the Pyrenees, where, likewise, they consort, though I have seen a good many Pyrenean specimens. There is little doubt that one's experiences there would be similar. I shall endeavour to unravel the London Pride tangle, with the assistance of the Irish evidence. It should be mentioned that in this group floral characters are of little service for diagnosis; the leaves are the important feature. In S. umbrosa the flowering stem is stouter, taller, and redder than in S. Geum, and the inflorescence and flowers larger; and the same thing applies to S. Geum, as compared with S. cuneifolia; but these and other floral characters are chiefly relative, and we have to turn to the leaves for the more important distinguishing characteristics.

First of all we have typical S. Geum, a slender plant of shady places, ranging in south-west Ireland from sea level to 3,000ft. The leaf blade is approximately circular in outline, heart-shaped at the base, hairy on both sides; the leaf margin is crenate (*i.e.*, the teeth are rounded), the leaf stalk is several times longer than the blade, slender, almost round in section, very hairy (Fig. 1, A). This is the typical Pyrenean and Irish form, and it is common in gardens. It is S. Geum sub-species eugeum var. Lapeyrousii of Engler and Irmscher's monograph. All the departures from this type tend towards umbrosa, and most, if not all, of them are hybrids. In spite of the many described "varieties," I believe that S. Geum (though classed as a "typus polymorphus" by Engler and Irmscher), is much less variable as a species than S. umbrosa. The only variations of any consequence that I have seen, which may not be due to umbrosa blood, have reference to size (there are some very strong forms in gardens), toothing (broadly crenate to crenate-serrate), and colour (dark green to yellowish on face, green to crimson on back).

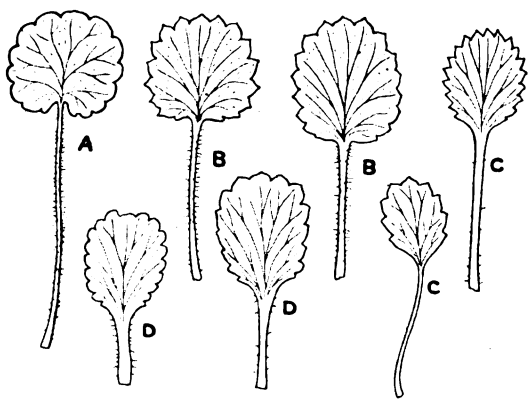

FIG. 1.
Half natural size.

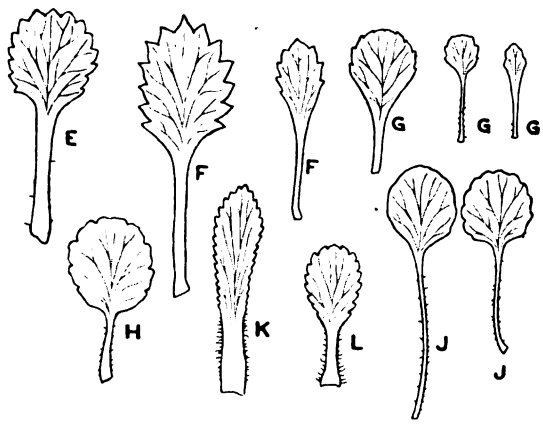

FIG. 2.
Half natural size.

In the first departures from type Geum towards umbrosa, represented by S. dentata of Haworth and S. Geum var. argute-serrata of Engler and Irmscher, the cordate leaf base goes, the leaf edges meeting the stalk at about a right angle, and the teeth tend to become sharp (Fig. 1, B, B). Following on these, we get a long series of forms which have been grouped under S. hirsuta of Linnæus, and which are responsible for many of the specific and varietal names which cumber the group. All are intermediate between Geum and umbrosa, but the mixture of characters varies greatly in regard to shape of leaf and of teeth, hairiness, and so on. That these are hybrids is evident from even a cursory study of the plants on their native ground, and has been proved by the experiments of Professor H. H. Dixon, as described in R. W. Scully's "Flora of County Kerry" (1916). Professor Dixon produced a full series of them synthetically by crossing the two species. One can see the same thing occurring in nature at places like Connor Hill Pass in Kerry, where the two species and all kinds of intermediates grow together on rocks by the roadside. A couple of these Kerry hybrids are illustrated (Fig. 1, C, C), but a black-and-white sketch cannot show the intermediate character of the colour, texture, etc., of the leaves, which is very striking. It is unfortunate that Professor Dixon's experiments and Dr. Scully's observations, which are so fully set forth in the "Flora of County Kerry," should not have come under the notice of the authors

Digitized by Google

of the Pflanzenreich monograph, though published two years before the appearance of the latter.

We now arrive at S. umbrosa, the London Pride, distinguished by its more or less obovate leaf blade (egg-shaped, with the broad end up), without hairs and tapering at the base into a foot stalk, which is stout, flat on face, often hairless and typically no longer than the blade (Fig. 1, D, D). Here an interesting point comes in. As a native, the species is confined (as I take it) to the Peninsula and Ireland, but, unlike S. Geum, the Irish form is not the same as the Pyrenean. In the latter the leaf blade is rather oval, being comparatively broad below, the leaf margin is crenate, or at least not *sharply* serrate, and the foot stalk seldom longer and often shorter than the blade. This Pyrenean plant is the one which Linnæus named umbrosa, so it stands as the type. It is the common form of gardens. The Irish plant, which appears to occur also in Portugal, has leaves narrower below and more wedge-shaped, with sharp teeth, and a stalk mostly longer than the blade (Fig. 2, F). It is the S. serratifolia of Mackay, S. serrata of Sternberg, and should be known as S. umbrosa var. serratifolia. It is widely spread along the south and west of Ireland, from sea level to the tops of the mountains, and has recently been found at 2,000ft. in Wicklow. Specially sharp-toothed forms of it are often seen in gardens, under a variety of names.

Most of the variants of pure umbrosa are developments in the direction of and beyond serratifolia, and away from S. Geum—the leaves more sharply toothed, the blade smaller or narrower or more wedge-shaped. I illustrate (Fig. 2, F, F) a couple of plants collected in Ireland to exemplify the range of variation.

Regarding the third species of the group, the well known S. cuneifolia, little need be said. Although the plant varies much in size, the leaf blade from almost circular to narrowly wedged-shaped in different forms (Fig. 2, G, G, G), and its margin from smooth to toothed, the plant is easily known by its small size, dark green colour, absence of hairs, and slender flower stems, only half the height of those of the other species. A hybrid with umbrosa is reported from Berlin, and I illustrate (Fig. 2, H) what seems to be the same thing from my own garden. Other garden forms are much larger than the type, with a very round leaf blade and very long leaf stalk (Fig. 2, J, J). I am inclined to suspect that there is some Geum blood in these; they are not referred to in the alpine and Pyrenean floras, which is suspicious, and the size and shape of the leaves are suggestive of Geum.

Finally, a number of hybrids are known between members of the Robertsonia group and other saxifrages. These include ? crustata × cuneifolia (pseudo-Forsteri Sündermann), Aizoon × cuneifolia (Zimmeteri Kerner), Cotyledon × cuneifolia (Jäggiana Brügger), Taygetea × cuneifolia (tazetta hort.), Aizoon × Geum sub-species hirsuta (Andrewsii Harvey = Guthrieana hort., and Wildeana Kunze), Geum × rotundifolia (hybrida Vill.). Of these the best known is Andrewsii (Fig. 2, K), a delightful plant, erroneously stated to have been found in Ireland. I follow Engler and Irmscher in setting this down as identical with Guthrieana, but as I recollect the latter in British gardens (I have not access to it at present), it is different, though evidently of allied parentage. The reference of Andrewsii to Aizoon × hirsuta (taken also from Engler and Irmscher) would make it a three-parent hybrid—Aizoon × umbrosa × Geum. It would seem more probable that it is Aizoon × umbrosa. There is another hybrid of this group which I had from Glasnevin, with a much broader leaf blade and more distinct foot stalk (Fig. 2, L). I do not know that it has a name. Like Andrewsii, it has the little marginal white, cartilaginous covering to the teeth which characterise the section Euaizoonia, to which S. Aizoon and its allies belong.

For garden purposes we may sum up the whole of this complicated group as follows:

1.—S. GEUM.—With round, hairy, long-stalked leaves, heart-shaped at the base and crenate on the margins. Leaf-stalk round and slender.

2.—S. UMBROSA TYPE.—The common garden London Pride, with oval or obovate, smooth, short-stalked leaves, wedge-shaped at the base, and crenate or crenate-serrate on the margins. Leaf stalk broad, flat on face.

3.—S. UMBROSA VAR. SERRATIFOLIA.—Differing from the last in its more sharply-toothed, more wedge-shaped leaves, with longer stalks.

4.—A crowd of hybrid forms, intermediate between No. 1 on the one hand and Nos. 2 and 3 on the other, many of them handsome plants but hardly worthy of names, as all intermediates exist.

5.—A few distinct varieties of umbrosa which deserve a place in the garden, like var. primuloides hort., and var. crenata hort. The former should be in every rock garden. There are also variegated sports for those who care for such things—one silver and pink, another with gold blotches, both inclined to revert to type.

6.—S. CUNEIFOLIA.—Small, dainty, dark green, without hairs; a pleasing rock plant in its various forms.

7.—Hybrids between the Robertsonia species and species of saxifrage of other sections; of these S. Andrewsii is the most important for garden purposes.

The readiness with which the species of the Robertsonia group, and S. umbrosa in particular, accommodate themselves to all kinds of garden conditions, has put them among the most widely grown of all rock plants, but has, at the same time, tended to blind us to their beauty. The London Pride is one of the handsomest of all saxifrages, both in leaf and flower, and if only it were rare or "miffy," with what pride would we point to a well grown plant in the rock garden!

I have to thank Miss Eileen Barnes for the figures. While they illustrate excellently the critical leaf characters, according to which diagnosis must be made, it would need a drawing of the whole rosette to give an adequate idea of the appearance of each form; and even then we should lack the details of colour and texture, which are often very characteristic.

GARDENS OF HEALING.—IV

HEALTH gardens can be of two kinds, those of the amateur who grows the beneficent plants for simple family medicines and for the interest and knowledge which their cultivation gives—and those of the professional, who cultivates them to dry and sell. The latter should reserve as large a piece of ground as possible for the poisonous plants, which are in great demand. These are easy of culture and include Belladonna Atropa, Datura Stramonium, Aconitum Napellus, Colchicum autumnale, Chelidonium majus, Digitalis purpurea, Solanum Dulcamara, Helleborus niger, Solanum nigrum, Scilla maritima and Ruta graveolens.

A large *red* label should mark the poison section of the health garden and every separate plot should have a smaller, but conspicuous red label bearing the word "Poison" as well as the name of the plant.

For the amateur's garden of healing it is as well to dispense with the poisonous plants, whose properties can, of course, only be made available by acredited professional people. The following well known herbs have healing, nourishing and tonic properties: colza, chervil, caraway, coriander, tarragon, fennel, rosemary and marjoram.

Flax (linum), the healing properties of whose seeds are so well known on account of the soothing oil which they contain; mustard (Sinapis nigra), constantly used in poultices for chest complaints and chills and also as an anti-poison; and saffron crocus, whose stigmas are so stimulating and nourishing, are three useful plants for the health garden. From the last named plant an infusion is made, either with a handful of stigmas or a tablespoonful of the crushed corms, which is an excellent tonic in cases of debility and loss of appetite, or for the depression which so often follows influenza.

Herb Robert and millet are two other interesting plants which are of service to mankind. The former is astringent and an infusion of the whole plant is an excellent gargle for ulcerated and inflamed throats and also as a lotion for healing sores and wounds. Bread made from millet flour is delicious as well as exceedingly nutritious and is used in cases of dysentery. An infusion of millet seed is an excellent drink for inducing eruption of the rash in cases of measles and scarlet fever. For deafness and to cure buzzings in the head, a simple cure is to fill little bags with equal parts of crushed millet seeds and common salt and to place them on the ears. The same relieves heavy and aching heads.

VICTORIA SLADE.

RHODODENDRONS IN NORTHUMBRIA

THE dwarf rhododendrons on the rockery here have mostly done well this spring. Some of the little ones of the R. fastigiatum group have been wonderful masses of colour, but all too fleeting owing to the hot weather, though at any time the flowers of these are only short lived. Larger growers, like R. ciliatum, having escaped all damage by frost, except for a few buds which were of no account, have made a fine display.

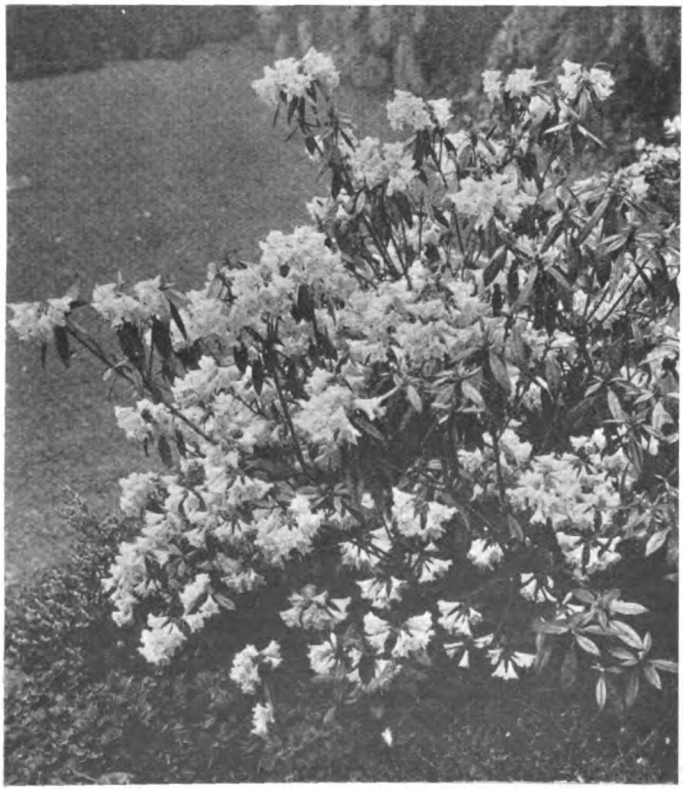
Most of the dwarf rhododendrons are planted in an open situation in soil largely composed of leaf-mould, with a small admixture of heavy loam. Probably such a soil is better than pure peat, and the small quantity of clay is good as a moisture holder. Taking the more interesting species in alphabetical order

R. CALOSTROTUM continues to do very well, and though not flowering so freely this spring as last, is growing vigorously. It shows a tendency to increase more in width than height. At all times it is a neat, low-growing little bush, but when in bloom it is a great beauty, with its large, bright pink flowers held well above the blue grey foliage.

R. CHAMÆCISTUS, correctly RHODOTHAMNUS CHAMÆCISTUS.—Although this species has the reputation of being rather fickle, a plant put in about two years ago is doing very well. As this species is found in the Eastern Alps on a limestone formation, at the time of planting an old bone was inserted in the hole, and, whether thanks to the old bone or not, it is flowering with great freedom this spring. The flowers are flesh pink with darker markings towards the centre and they are very lovely.

R. CHRYSEUM looks healthy, and though its pale yellow flowers have not yet been produced as freely as in the case of primulinum, it promises in time to make an attractive little bush.

R. CILIATUM cannot always be called a dwarf rhododendron, but if grown in an open situation after reaching about one foot in height, it will spread out into a flat-topped bush, and increase in height very slowly. Unfortunately, its flowers and buds are easily damaged by frost, and as it is an April bloomer, it is almost useless where spring frosts are prevalent.



WITH CAREFUL ATTENTION R. RUBIGINOSUM FORMS A HANDSOME AND SHAPELY BUSH.

RHODODENDRON IMPEDITUM WHEN GROWN AS A BUSH REACHES A FAIR HEIGHT.

Here it gets caught about every other year. When it does escape all damage its large white, pink-flushed flowers, as fine as any greenhouse azalea, make ample compensation for previous disappointments.

R. DICHROANTHUM.—A plant put in last autumn is growing satisfactorily. It may eventually be too big for a small rockery, but could not be left out.

R. FASTIGIATUM is one of the best of the low-growing kinds, and forms a wide mat of silvery blue-green foliage, which is attractive all the year round, and in April-May is covered with a profusion of lilac or lavender-blue flowers. It is very accommodating and easy to please, and small rooted cuttings quickly form nice little bushes.

R. HIPPOPHÆOIDES is another good purplish-blue of an erect habit of growth. It has an advantage over fastigiatum in that its flowers last fresh for a longer time.

R. IMPEDITUM forms a neat, compact little bush, with glossy dark green leaves and lavender or purple flowers with conspicuous stamens like fastigiatum and scintillans. It seems to be quite easy to grow.

R. INTRICATUM is also a good mauve or lilac sort that is especially valuable on account of its blooming after most of the others are over.

R. LEDOIDES might be called the daphne-flowered rhododendron. Its pink flowers at their best are very beautiful and last well, but it is not so easy to grow as most of the others. Here, its chief requirements seem to be at least half shade and a moist, but well drained mixture of leaf-mould or loam.

R. MOUPINENSE has grown quite well, but has not yet succeeded in producing its February flowers. Perhaps it will be able to do so some year if we get a sufficiently long spell of mild weather, or a winter hard enough to keep it back till spring.

R. MYRTILLOIDES is too young yet for one to say more than that its small glossy dark green leaves, white underneath, look attractive, and that it is growing well.

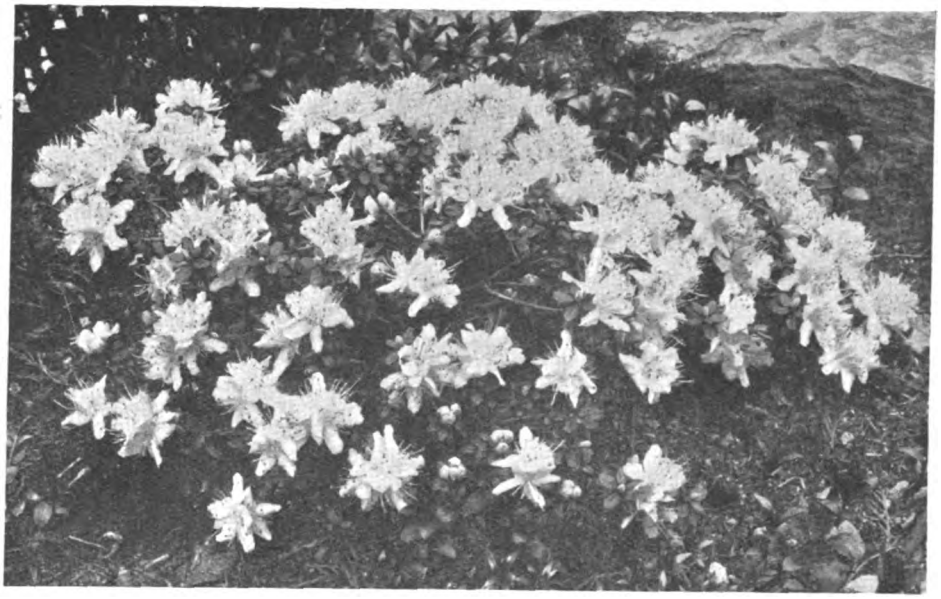
R. PRIMULINUM is one of the indispensables in any collection, however small. It is a pity its pale yellow flowers are individually so short lived, but they are produced in such quantities that a bush in full bloom is a fine sight.

Digitized by Google

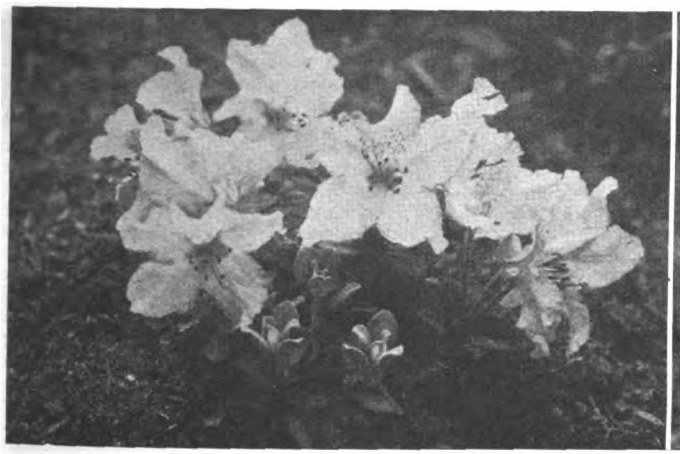
R. RACEMOSUM is very accommodating, and is rightly now a favourite. As it flowers all up the previous year's shoots it looks better as a vigorous young plant making long annual growths than after it gets older.

R. RUBIGINOSUM if left alone may eventually get far too big for almost any rockery, but it flowers so freely in a young state, and springs so readily from the base if cut back, that it may with advantage be included. Although the individual flowers are not large, they are of a bright and attractive pink, and produced in clusters containing as many as twenty-five single flowers at the ends of the strong shoots. As its bark seems liable to split near the ground in very severe winters, perhaps it will never become very large, unless in the west or near the sea.

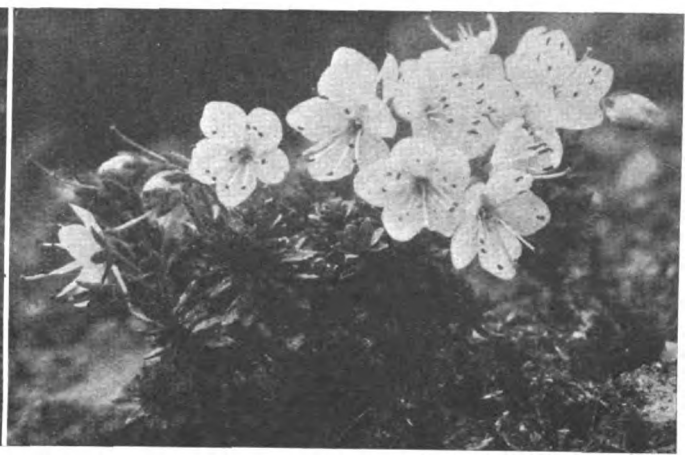
R. SCINTILLANS has given no trouble here. It has a loose habit of growth, and its lavender blue flowers are freely borne and last well.



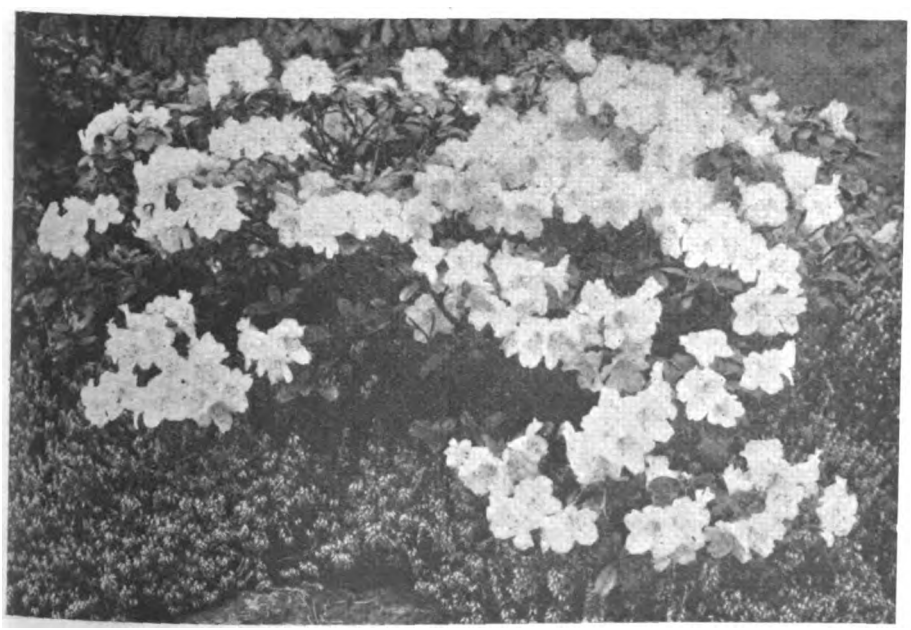
RHODODENDRON FASTIGIATUM, ONE OF THE MOST ATTRACTIVE OF THE DWARF SPECIES WITH ITS SILVERY GREEN FOLIAGE AND LILAC BLOSSOMS.



RHODODENDRON CALOSTROTUM, OF NEAT AND COMPACT HABIT AND CARRYING LARGE BRIGHT PINK FLOWERS.



ONE OF THE LIME LOVING SPECIES, RHODODENDRON OR RHODOTHAMNUS CHAMÆCISTUS.



RHODODENDRON CILIATUM IN COMPANY WITH ERICA CARNEA WHICH ACTS AS A MEASURE OF PROTECTION AGAINST SPRING FROSTS.

R. WILLIAMSIANUM demands shade and moisture, and a well drained soil largely composed of leaf-mould. Here it has not yet flowered. If it gets too much sun, or the soil is badly drained, it seems liable to die off suddenly, but its leaves are so distinct and its flowers so fine, that it is well worth a little extra trouble.

Anyone living in a limestone district who would like to try these dwarf rhododendrons, would find a foot of lime-free soil laid down on top of their limy soil to be ample, and provided there was no higher limy soil in the near vicinity, the new soil should keep quite sufficiently lime-free to give just as good results as can be got anywhere. Of course, limestone stones would have to be avoided for such a bed, and a guard kept against using very hard water for watering in dry weather.

In conclusion, I would recommend all rhododendron lovers to read "Rhododendrons for Amateurs." This book contains much useful information regarding the culture of the species I have mentioned.

R. B. COOKE.

DELPHINIUMS AT VINCENT SQUARE

QUITE a feast of colour met the eye on entering the Royal Horticultural Society's Hall on the occasion of the ordinary fortnightly show on June 23rd and 24th. The delphiniums were undoubtedly the principal feature of the show and provided a splash of colour that is all too rarely seen at the Hall. Blue and shades of blue to be truly appreciated require the sun's rays to supply a warm tone to the colourings and, naturally, are seen to best advantage in the garden itself. But, nevertheless, the effects *en masse* was magnificent, and if one's glance took in the brighter tints of the sweet peas and the roses, then the picture was both complete and wonderful.

Both Messrs. Blackmore and Langdon and Mr. T. Bones had outstanding exhibits. In each case the size and form of the flowers and general arrangement on the spike were perfect. The flowers were evenly placed—not in the least overcrowded nor yet thin—and the spikes beautifully tapering. The Shah was a variety of unique colouring and great height. The semi-double flowers are deep rosy-lavender. Mrs. Townley Parker was also noticeable. It is one of the best pure blue singles. The huge spikes of Mrs. A. J. Watson (deep mauve), and Robert Cox (rich blue and rosy-lilac), towered above the rest. Edward Bromet, a variety of purplish blue with a white eye; Millicent Blackmore, with blue and mauve flowers symmetrically placed on long tapering spikes; and Marjorie Ferguson, a beautiful sky-blue and mauve, were all much admired. Walter T. Ware, Purple King, Mrs. Shirley, Mrs. Christie Miller, Sir Douglas Haig and Pannonia were also seen on the stand of Messrs. Blackmore and Langdon.

Mr. T. Bone is to be congratulated on the excellence of his delphiniums. Luxor was the most striking variety. The tall and stately spikes with their semi-double flowers of rich blue and purple stood out from among the rest. A variety of great strength and vigour was The Rev. Charles Storr. It has large semi-double flowers of bright blue suffused with rosy-mauve. Miss Winifred B. Mackintosh was a delightful colour, being soft blue suffused with mauve and having a conspicuous white eye. Other good varieties were Mrs. H. Kaye, Dusky Monarch, Rev. E. Lascelles, The Alake, Elsa and Mrs. T. G. Baker.

Some fine delphiniums were staged by Messrs. Waterers and Mr. T. Carlile. Among Messrs. Waterers' exhibit were the varieties Blue Bird, Daphne, Harry Smetham, Walter T. Ware, Elsa, Mrs. Creighton, Mde. Violet Geslin and King of Delphiniums. Blue Bird is an intense blue, and about the nearest to a true blue self. It is one of the earliest to bloom and has graceful, tapering spikes.

Among the delphiniums exhibited by Mr. T. Carlile were Norah Ferguson, Blue Lagoon, Mrs. A. C. Kendrick and Mrs. Victor Hewlett. Barbara, Phyllis Charrington, Lovely, Barbara Thomas and Pannonia were also seen. Norah Ferguson, a delphinium which has received much attention, is semi-double, with flowers of a beautiful shade of pale blue blended with soft pink.

Messrs. Bunyard had a large ground exhibit of delphiniums. Such varieties as Medea, Empress Queen, Guardsman, Walter T. Ware, The Alake, Lavender, Mrs. Creighton, Robert Cox, Lizzie Van Veen and Minerva had been selected to fill the large oval bed. The group was most effective. Messrs. R. H. Bath were exhibiting peonies and delphiniums. The latter formed a pleasing contrast with the pinks and reds of the peonies. Perfection, a tall light blue variety; Dusky Monarch, a light purple with a striking black centre; Splendour, a pale sky blue and mauve; James Kelway, Ladye Faire and Ida R. Elliott were shown by this firm.

Messrs. Kelway and Son also exhibited delphiniums, together with their famous peonies. The branching habit of the varieties shown by them was particularly noticeable. Jewel of the West, Thunder Cloud, Lloyd George, Smoke of War, Bluebeard and Sir Alfred Keogh, were a few of the best. Lloyd George is a bright blue and violet delphinium with a white eye and large flowers.

A small but striking exhibit, staged by Mr. J. Burrell, was formed of one variety of delphinium alone. It is known as Mrs. W. J. Sanderson and is of a brilliant blue, with a conspicuous white eye. The spikes are of medium size and the flowers evenly placed thereon. For the herbaceous border this will be a most useful and effective variety.

Messrs. Lowe and Gibson had some exceedingly beautiful delphiniums. These, all raised from seed, were exhibited to show what good flowers in a great variety of colours can be obtained by such a method of propagation.

Several firms staged very good exhibits of roses. Some of the specimens shown by Messrs. Alex. Dickson and Sons were perfect and very fragrant and the whole exhibit was well arranged. A truly wonderful colour is Scarlet Glory, a vermilion scarlet hybrid tea, with flowers of good form and abundant dark green foliage. Fred. J. Harrison was another beautiful rose with cardinal red petals shaded blackish crimson towards the outer edge. Saltaire, Sunstar and Ethel Somerset were very effective. Some good varieties could be seen on the stand of Messrs. Benjamin R. Cant and Sons, and among them Lady Roundway, a deep coppery chrome; C. V. Haworth and Sovereign, with its deep golden yellow flowers and well shaped buds, were noticed.

Several new hybrid tea roses were shown by Messrs. Chaplin Bros., one, Mrs. Herbert Nash, received an award of merit. Two others were Lady Sydney Eardley Wilmot, a coppery salmon novelty, and Eric Holroyd, a brilliant red, shaded gold at the base. Messrs. Samuel McGredy and Son had chosen among many others, Diadem, Lord Charlemont, Vesuvius and Mrs. Henry Morse for their exhibit. Mr. George Lilley had two good hybrid teas, one being Marcia Stanhope, a sweetly scented white rose, and the other Lady Constable, a bright salmon pink. Mr. J. H. Pemberton staged many varieties of roses, some of them of his own raising. Anne, I. Zingari, The Adjutant and Aurora were a few of those introduced by this specialist.

There are few garden lovers who can fail to appreciate the genus campanula in all its many forms and varieties and which lends itself to such an infinite variety of situations in the garden. The so-called Canterbury Bells rank among the finest of our herbaceous flowers, and it is only on an occasion such as this, when Messrs. Ladhams of The Shirley Nurseries, staged a number of fine varieties, that one has a chance to pay one's respects to the genus. One of the most notable varieties was Everest, carrying large bells of that delicate pale shade of blue always associated with the flower. Another was Faerie Queene, of a still more translucent tone, with wide open bells sitting more squat on the stem. With this variety a fine contrast is obtained between the creamy spreading stigmas and the blue of the corolla. Snowdrift and Snow Queen are both pure white varieties, with well shaped bells, while Queen of June is another of the blue sorts with large, rather spreading flowers, which tend to lose their bell shape. Two semi-double forms of interest were Shirley, with well shaped blue flowers carried on long stems, and The King, of a much deeper shade, almost running to mauve.

One of the finest flowers we have for summer decoration in the garden is undoubtedly the sweet pea, with its wealth of colour and flowering propensities. Both Messrs. Dobbies and Messrs. Sutton's stands were magnificent. On the former such varieties as Powerscourt, Mermaid, Mrs. Tom Jones, which to our minds still remains as the best blue variety we have; Grenadier, with large flowers of a geranium colour; Dobbie's Cream and Magnet, of a delicate cream pink shade were noticed. Messrs. Sutton's staged quite a number of the same varieties, with, in addition, old sorts, such as Majestic Cream, Mammoth and The President Harding. Among the newer kinds, although it seems invidious to single out any we noted Pimpernel, of a vivid scarlet, and Miss California, of a shade of rich salmon cream pink on both stands.

Very few alpines were shown, but F. G. Wood of Ashtead made a decorative exhibit with masses of orange and copper mimulus, grouped at the foot of a Japanese maple and spikes of Primula littoniana, against a dark background of dwarf conifers. The exhibit included Dracocephalum Isabellæ, a recent introduction from western China, Gentiana decumbens alba and Œnothera mexicana, with almost stemless flowers of vivid pink.

Messrs. Waterer showed Codonopsis ovata, pale blue bells decorated within by geometric designs in orange, purple and black; Gentiana macrophylla, a dull, cluster-head gentian; the strange and brilliant Sedum sempervivum, looking at present like a pile of terra cotta tiles, but surmounted by a fat bud that will presently break into a spray of blood-red flowers; Convolvulus Cneorum and Campanula turbinata pallida, with its relatively enormous flowers of greyish blue.

Among other exhibits were the following:

Alpines.—Messrs. Bakers, Ernest Dixon, R. Tucker.

Carnations.—Messrs. Allwood Brothers, C. Engelmann, Lowe and Gibson and Stuart Low and Co.

Greenhouse Plants.—Messrs. L. R. Russell and Co., and Stuart Low and Co.

Hardy Plants.—Messrs. J. C. Allgrove, Barrs, T. Carlile, Chalk Hill Nurseries, Godfrey and Son, K. and E. Hopkins, Harkness and Sons, M. Prichard and F. G. Wood.

Irises.—Messrs. Barrs and M. Prichard.

Orchids.—Messrs. Sanders and Stuart Low and Co.

Strawberries.—Messrs. Laxton Bros., and J. A. Mix.

Shrubs.—Mr. Charles Turner.

St. Brigid Anemones.—Messrs. Reamsbottom and Co.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

PHLOMIS FRUTICOSA.—This interesting shrubby member of the Labiatæ has long been cultivated in this country, and it is passing strange that it has not obtained an award previously. It is an interesting evergreen shrub, bearing dull green wrinkled leaves like the common sage, with, in addition, numerous stalkless, bright yellow flowers, characteristic of the family. Shown by the Director of the Botanic Gardens, Cambridge.

OZOTHAMNUS ROSMARINIFOLIUS.—This well known shrub, popularly called "Snow in Summer," was represented by a well grown pot plant and long flowering sprays. It is a characteristic dark evergreen shrub with small smooth leaves closely arranged on the branches and clusters of quite small, pure white flower heads. It thrives excellently under the protection of a wall. Shown by

Digitized by Google

Sir William Lawrence, Dorking, and Mr. Allgrove, The Nurseries, Slough.

DEUTZIA SCABRA LATIFOLIA. This is a variety of the ordinary type species. It carries rather loose panicles of pure white flowers with rather spreading petals. The leaves are ovate in shape and produce a good contrasting effect with the blossoms. Shown by the Hon. Vicary Gibbs, Aldenham.

ROSE DAME EDITH HELEN.—This was a fine hybrid tea variety bearing large, shapely blooms of a fine shade of pink, carried on stiff wiry stems. The foliage was of good colour and provided an excellent setting for the flowers. Shown by Messrs. Alex. Dickson, Limited. Manchester.

ROSE MARCIA STANHOPE.—Another handsome hybrid tea variety, bearing fine pure white blooms of a rather long, oval shape in the bud. The petals are of good substance, while the foliage is of excellent texture. Shown by Mr. G. Lilley, Slough.

ROSE LADY WORTHINGTON EVANS.—This is one of the finest crimson-red hybrid tea varieties we have seen. The individual flowers are of good shape and form, and the overlapping petals are of good substance, being covered with purplish bloom. The dark green, glossy leaves set the flowers off to advantage. Shown by Messrs. Alex. Dickson.

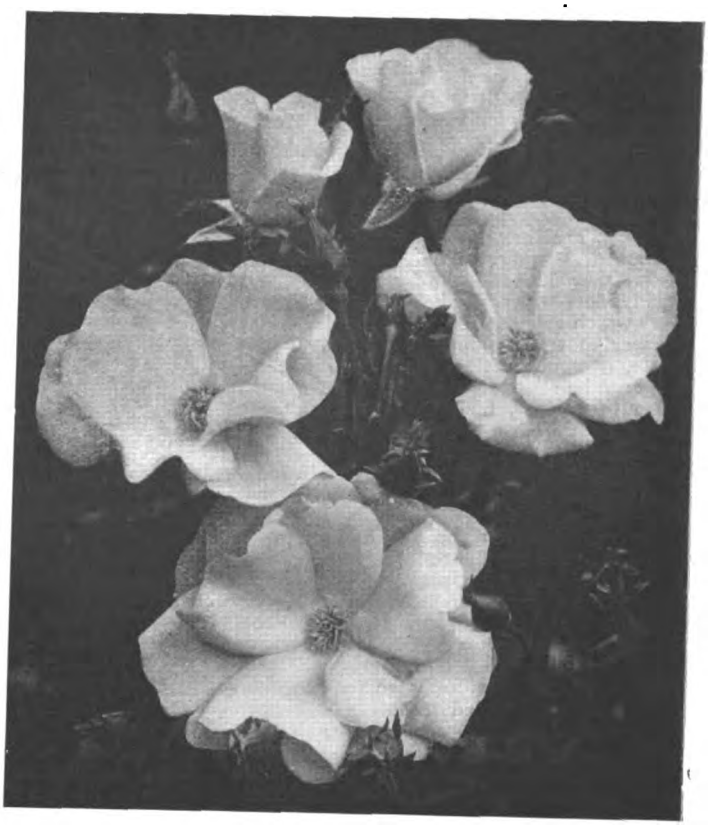
ROSE MRS. HERBERT NASH.—An excellent, sweetly scented hybrid tea variety with large handsome blooms of a deep crimson colour. Shown by Messrs. Chaplin Brothers.

ROSE ELSE POULSEN.—This is a very fine, large, single polyantha variety, with flowers composed of beautifully frilled petals of a delicate salmon pink shade. The foliage was of a hue of glossy green with a tinge of bronze which becomes so pronounced in the autumn. The plant appears to be an excellent doer, judging from the number of buds on the sprays shown. It is certainly a variety which ought to become popular in the future Shown by Messrs. Prior. Colchester.

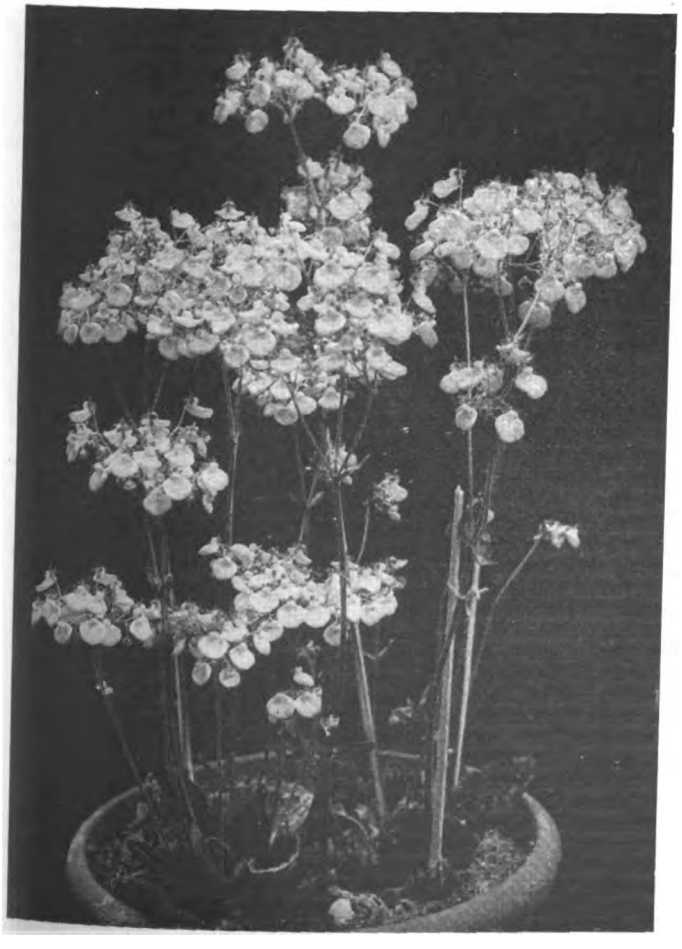
CAMPANULA PERSICIFOLIA GIGANTEA CORONATA SHIRLEY.—A rather fine semi-double form, carrying bells of a shade of delicate porcelain blue. The individual flowers are almost 1½ins. across, and looked well drooping from the tall stems. Shown by Messrs. B. Ladhams, Limited.

CALCEOLARIA PRATENSIS.—This is a small pale yellow flowered form which appears to be admirably suited to pot culture. The flowers are borne gracefully in loose clusters on stems which reach about 1–1½ft. high. The leaves are mostly basal and slightly ovate lanceolate Shown by Sir William Lawrence, Bt., Dorking.

TITHONIA SPECIOSA.—This is a shrubby, half-hardy annual from Mexico, belonging to the composite family. The large, almost orange-scarlet heads are striking and about 3ins. in diameter, with their cushion of yellow stamens in the centre. The leaves are more or less three-lobed and somewhat heart-shaped. Shown by Mr. J. B. Body, Hindhead Court, Hindhead.



THE HANDSOME FRILLED BLOSSOMS OF ROSE ELSE POULSEN.



CALCEOLARIA PRATENSIS OF GRACEFUL HABIT.

ACIDANTHERA CANDIDA.—This is a slender and more or less erect leafy member of the iris family. The pure white flowers are borne on lax spikes and look exceedingly graceful, their appearance being enhanced by the long linear leaves. The flowers are very sweetly scented. Shown by Mr. W. Van de Weyer, Clyffe House, Dorchester.

HEMEROCALLIS WINSOME.—This is a rather dull pale yellow-flowered variety of the day lily. The petals are rather spreading and somewhat reflexed in the open flowers, which are well borne on long scapes. Shown by Mr. G. Yeld, Gerrard's Cross.

DIANTHUS GIANT-FLOWERED FRILLED.—A pot of these frilled varieties of all shades, from white to pink and scarlet, was shown. Some of the flowers were exceedingly graceful and attractive, while with others the colour did not appeal to us. Shown by Messrs. James Carter and Co., Raynes Park.

CLEMATIS QUINQUEFOLIOLATA.—This is a very attractive species from Central China, allied to C. Meyeniana. The leaflets are lanceolate, while numerous white flowers, about ¼in. to ⅜in. across, are borne in clusters or cymes. Shown by Mr. E. M. Preston, The Warren, Hayes, Kent.

ORCHIDS.

LÆLIO-CATTLEYA BEATRICE DE HERRIARD (C. Veiris × L.-C. Ettrick).—A fine addition to the yellow section, the flower shows much of the characters of C. Veiris, a garden-raised hybrid composed of the two species C. bicolor and C. aurea. Award of merit. Shown by Mrs. Beatrice Jervoise, Herriard Park, Basingstoke.

ODONTOGLOSSUM LADY COLMAN (Lambeauianum × "V.C.").—This promising seedling bore a single flower of large size and massive formation, of slight rose tint, the segments heavily blotched with dark crimson, the roundly formed labellum white, with a crimson blotch in the centre, and a bright yellow crest. Preliminary commendation. Shown by Sir Jeremiah Colman, Bt., Gatton Park, Surrey (gardener, Mr. Collier).

ODONTOGLOSSUM LADY HOLMDEN (Lord Pirrie × Amethyst).—This young seedling carried but one flower, having the segments broadly formed and almost covered with dark purplish blotching, the elongated labellum crimson-purple, except for the white apex. Preliminary commendation. Shown by Sir Jeremiah Colman, Bt.

ODONTOGLOSSUM EXIMIUM VAR. GATTON TRIUMPH (crispum solum × ardentissimum var. J. Gurney Fowler).—An interesting result, and the only seedling out of thirty so far flowered in this batch which inherits the peculiar crimson-coloured labellum of crispum solum. There is an occasional circular blotch of crimson on the other segments. Preliminary commendation. Shown by Sir Jeremiah Colman, Bt.

CORRESPONDENCE

PRIMULA PULVERULENTA BARTLEY STRAIN.

SIR,—Judging by the show reports and the amount of correspondence I have had about these primulas, there seems to be a good deal of misunderstanding about them. I will, therefore, explain what they are. They are *not* hybrids, but pure pulverulenta all through; nor are they the variety Mrs. R. V. Berkeley. This variety—Mrs. Berkeley—was a sterile sport which originated in the Coombe Wood Nursery of the late firm of Veitch. Being sterile, it would not set seed, and therefore could not be raised from seed. As it was such a beautiful plant, I started some years ago to try to obtain a fertile form that would reproduce itself from seed. After several years' work, I got a strain that gave a fairly good percentage of pink forms which has now become a 100 per cent. strain. In this strain there are four or five different pink forms, all good enough to keep, and this year I have about 12,000 plants, out of which I have found only five reverting to the type—*i.e.*, the purplish crimson flower—so that there is now no question about its reproducing pink. As the various forms appeared to be more attractive in a mass mixed together, I have never troubled to isolate and grow each one separately, and as the bumble bees cross the flowers of the various shades, so the seed from any one form will reproduce all or any of the various shades. No doubt by isolation any particular form could be reproduced exactly from seed. The plant is easily grown, and is of very good constitution, and thrives in a cool moist shady place where it does not get waterlogged.

It has been suggested to me by several people that I should use some name by which the strain can be identified. I have, therefore, decided to use the name above, which describes the various shades as a whole.

The following forms have been named: Lady Thursby, A.M., R.H.S., 1924, rose pink, yellow eye; Bartley Blush, blush pink with light eye; Hew. Dalrymple, blush pink with dark eye; and Bartley Pink, pink with light eye.—G. H. DALRYMPLE.

A CLIMBING ROSE.

SIR,—Can any of your readers tell me the name of a free-growing climbing rose, with coppery pink buds which open lighter, but of which the distinguishing feature is the strong perfume of lemon-scented verbena? This rose blooms profusely in May, in the gardens and villas on Lake Como, but I am unable to trace it by this description in any of our rose catalogues, and shall be grateful if anyone can tell me the correct name, and also whether it would be likely to succeed in this neighbourhood.—M. L., *Bournemouth.*

CHARM OF MINIATURE DAFFODILS.

SIR,—I quite agree with Mr. Edward Cahen, in a previous issue of THE GARDEN, on the "Charm of Miniature Daffodils and Narcissi." To my mind there is nothing so pretty in a rock garden, and for edging, than these smaller species, and I have read the article with very great interest indeed.

May I be permitted to correct a little however, his statement regarding Narcissus calathinus: this species (for species it is, and not a form of triandrus) has been known much earlier than Mr. Peter Barr's famous visit to the Glenans. It is very fully described in "Burbidge"; also, it is not at all extinct in the Glenan Islands: it has been collected on two occasions within the last five years for me, and distributed among my friends.

It is to be found at Drenac and St. Nicholas, and my botanical friend has found, on the neighbouring island of Huat, the Mediterranean Ismene, surely a long way from its normal habitat, but which, of course, like calathinus, is accounted for by the very mild climate due to the Gulf Stream.

Incidentally, it was Narcissus triandrus and cyclamineus which launched me out with narcissus-growing over thirty years ago: for it was in the garden of Mr. Brockbank of Didsbury, about 1889, that he showed me, in his alpine house, the first plants of these two species which were then in bloom, and . . . probably from the very bulbs Mr. Peter Barr discovered in Portugal.

I have seen some very fine *hardy* hybrids raised by Mr. C. F. Johnson of Heaton Mersey, the next village, obtained by crossing Narcissus triandrus by Mme. De Graaf.—J. HENRY WATSON.

A SEEDLING BROOM.

SIR,—I am sending you under separate cover a portion of a seedling broom which may be of interest to you. It was picked on the common, about a mile away from any cultivated broom.

You will doubtless remember that Genista Andreanus, the first break in colour from the ordinary scoparius, was found on a common in France, I suppose some thirty years ago, by the late M. André. I have not heard since of any variation being found, except in nurseries and gardens where natural crossing takes place. I expect the origin of this present cross is due to the fact that in an adjoining garden a mile away are now many forms of Andreanus and the bees have carried the pollen. I suppose one may conjecture that in future years it is quite within reason to imagine that the glorious masses of the common yellow broom we see spread over the countryside, will be changed into many seedling coloured forms, such as the one I am sending you, and therefore by man's work some aspects of the countryside will be changed; but, as is frequently open to question, will the result be an improvement or otherwise?—R. W. WALLACE, *Tunbridge Wells.*

PLANT HUNTING.

SIR,—May I thank you and Mr. H. T. Denham, M.A., for kind remarks about my recent articles and say how entirely I agree with the warnings to collectors to respect both the plants and the ground around them, and to remember that they belong to the peoples who show us much hospitality? Mr. Denham's letter is most useful and opportune. I would emphasise the desirability of getting alpine plants and seeds from nurserymen whenever possible. I also think a small rucksack is better than a fishing basket, however well curved to fit the shoulders. Plants would keep fresh longer in the former, and as most collected plants are quite small, the question of rigidity and bruising hardly counts. But a large plant-tin (vasculum) will take an ample supply of alpine plants suitable for the garden. I have found a sponge bag useful for quite small roots when collecting for the herbarium, especially when on climbing expeditions. In the quotation (page 309) from John Ball's warning about frontiers, it should be pointed out that in speaking of the Tenda district, the words "on military matters" were omitted from the sentence "any conversation with natives . . . should be carefully avoided." I want again to recommend the excellent little "Atlas Colorié de la Flora Alpine," by Beauverie and Faucheron, 1906, after Hegi and Dunzinger (Baillière et fils, Paris). The thirty plates with numerous figures are less crude than some in "Hoffman" or Schroeter's "Flore des Alpes," the descriptions equally good and the volume (so little known in England) is no larger or heavier than the former.—H. S. THOMPSON.

ALUM FOR SNAILS AND SLUGS.

SIR,—With reference to my communications on the above subject of January 10th and February 21st, 1925 (Vol. LXXXIX, pages 25 and 107), I may say that since then I have made an experiment in order to determine how strong an alum solution may be made before it will damage plants when they are watered and sprayed with it.

I commenced with a saturated solution of the material, which is 1 in 10 (approximately 1lb. to 1 gallon of water) at ordinary outdoor temperatures, and I, of course, anticipated that this would require some dilution before it could be safely applied to the roots of plants. I was, however, agreeably surprised to find that such was not the case, and that it produced no injurious effects whatever on the plants experimented upon, namely, a shrubby veronica and a cultivated strawberry. Both of these were in 3in. pots. The former consisted of four cuttings which had been struck in the pot two or three years ago and had grown into a clump about 12ins. high. The other was a Garibaldi strawberry plant which had been pegged down into the pot in the previous season. In both cases the roots were very much pot-bound, and in the case of the veronica they had made their way through the hole in the pot into the soil beneath, in which they had formed a large mass. These were severed from the others at the base of the pot, so that the veronica was severely handicapped from the start. The plants were placed side by side, and daily the roots were drenched with the alum solution and the foliage sprayed overhead with it for about a fortnight. The result was rather surprising, no damage whatever being discernible, and the experiment proved to my satisfaction that if plants of this sort are so resistant to injury from such drastic treatment as this, a saturated solution of the material may be applied to ground occupied by a crop with every confidence that no injury will result to the plants. And in this form it is much more effective than when applied in the dry state, in which form it acts more as a preventive than as a destroyer of the pests.

I think Mr. Cahen (page 94) is wrong about alum acting in the same way as common salt. As I stated in my communication of January 10th (page 25), slugs and snails can slough off salt and soot, not so alum. I also think Mr. Ansdell (page 149) is in error in stating that sulphate of aluminium (used in the Wisley experiments, and which requires lime to be added to it) is alum. Alum is a double sulphate of aluminium and potassium (or ammonium), and as it does not require lime it has the advantage over the Wisley formula that it contains no grit, and therefore does not require to be strained before use to prevent choking of the nozzles of the sprayers. I was pleased to observe that Mr. Ansdell and "H. R. C." (Wimbledon) had met with success with alum.

Soot is a filthy material to use among vegetables, and poisons, such as Paris green, are rather dangerous.—A. D. RICHARDSON, *Edinburgh.*

A REMEDY FOR EARWIGS WANTED.

SIR,—I have a bed of about 400 dwarf zinnias. They were fine plants, but now the centres and young shoots have all been eaten. I discovered earwigs were the enemy by going out late at night with an electric torch, when I found the plants covered with these hungry insects. I have placed flower-pots half full of hay on the bed, but have caught none. There are no slugs or snails. I have sprayed with paraffin soap, but of no avail. Can anyone tell me a remedy?—L. P., *Leatherhead.*

NOTES FROM CONTRIBUTORS

WINTER FLOWERING STOCKS.

FROM time to time we are reminded of the beauty and fragrance of stocks in the garden. Often, however, the worth of those of the winter-flowering sorts for pot culture under glass is not sufficiently appreciated. It is not so much a question of the amount of warmth one is able to give them as it is of shelter. Cool treatment is best for them, and if the house is cold, it simply means that their flowering is deferred until the spring days arrive. July is a suitable period for sowing seed. Pans or boxes of soil, light in character, are, I find, better than sowing out of doors. These ought to be placed in a cold frame having a north aspect to ensure coolness for part of the day. Six-inch pots are ample for the final potting, the compost for which should be made up of loam, leaf-mould and well rotted manure. It is curious that the average owner of a greenhouse misses winter-flowering stocks. East Lothians with very little warmth will open their fragrant spikes in early winter, and almost simultaneously that excellent section Beauty of Nice in very attractive colourings, and their preparation is not difficult, but one ought not to let July pass before getting seed in.—W. LINDERS LEA.

SAXIFRAGA CRASSIFOLIA.

SOME of the larger and better forms of the Siberian saxifrages of the Megasea section are extremely useful plants. The fine branching heads of rose-pink flowers are singularly attractive in spring, especially where a bold effect is desired, and while the elephant-ear foliage is handsome at all seasons, it assumes striking autumnal tints of bronze and crimson. S. crassifolia (and I may include its near ally, the beautiful S. Stracheyi) always looks well associated with masonry. It is, therefore, a good plant for terraces, the margins of steps or for covering low retaining walls. Moreover, this saxifrage is especially happy where the root-run consists of little more than stones and old mortar, the poor fare and restricted root activity leading to more copious flowering without unduly checking foliage development.

A FINE EDGING OF S. CRASSIFOLIA.

In the illustration accompanying this note a fresh rose-pink variety of S. crassifolia is shown entirely occupying the top of a retaining wall, the plants being rooted in the stone and mortar. Incidentally, the saxifrage forms an attractive edging to the walk. Full exposure is generally desirable, and there must be no lack of moisture in spring.—A. T. JOHNSON.

CALENDULAS: THEIR CULTURE IN POTS.

THE highly coloured orange and clear lemon-tinted flowers of calendulas are prized in the garden for their usefulness for cutting in these days, but comparatively few think of them for late autumn and winter blooming under glass. A friend of mine was astonished to find that from a pinch of seed sown last August and the plants potted on in small pots, and finally in 5 or 6 in. pots, he was able to have quite a glow of colour in December and January in his greenhouse, with merely sufficient heat to keep out frost. We know their hardiness out of doors, that they will often go through a winter unhurt; that "self sowers" bring plants in our borders; but, somehow, we fail to associate their culture with that of other plants in pots. They need no fuss, the cooler the house the longer duration of bloom, and old loam with a little sand will suffice for them.—CLAREMONT.

ROCK GARDEN GYPSOPHILAS.

ALTHOUGH Gypsophila paniculata is a distinct favourite, the dwarfer species of this genus are far from being well known, and are seldom mentioned among the common rock garden flowers. Nicely placed and planted in little groups so as eventually to form close mats or tufts, they are really pretty things; they flower exceedingly well under appropriate conditions, they keep in blossom for quite a long time, and the cushions of foliage, even when not in flower, look quite attractive.

The dwarf gypsophilas must have a medium soil with good body in it, not a porous, barren sand or a stiff clay. Again, they need lime, and they will grow splendidly over limestone rock or in ground with which has been mixed some old mortar, ground shells or limestone chunks. Every year should see a top-dressing given of manure and soil, or fertiliser mixed with loam and leaf-mould, in order to keep the plants robust and strong.

G. cerastoides is a real dwarf, seldom exceeding 3ins. in height; its white flowers veined with red are very pretty and plentifully produced. G. repens is better known. It also is a trailing species, but decidedly larger than the former; its flowers are a light rosy pink. There is a large variety of repens to be had also, very distinct and still small enough to be classed as a dwarf, and we have another variety with white flowers not quite so fine as the type itself.—HUGH H. AITKEN.

A LETTUCE HINT.

UNLESS it is desired to clear the ground, here is a hint worth noting when gathering lettuces. Do not pull up the plant altogether or cut it close to the ground, but leave two or three of the outer leaves on the stump. Loosen the soil round the plants and, if needful, supply water. In a very short while two and sometimes three small buds appear at the top of the stump. These grow rapidly and soon develop into small lettuces. Quite often these second crop lettuces form excellent hearts, and they are always exceedingly crisp and tender. This is a very good plan to adopt where the first crop of lettuces has been rather a failure, particularly if that failure is due to a dry, hot season. The writer has found this plan succeed with all kinds of lettuces, and the idea is well worth carrying out.—S. LEONARD BASTIN, *Bournemouth*.

SCOTS PINE ON A CHIMNEY.

IN or near the year 1914, a flourishing tuft of something green was observed at the top of a cottage chimney that stands about 30yds. from a hedge in which there are some old Scots pines. It was soon recognised as a seedling pine. It grew on quite happily till 1921, when the severe drought of that summer brought its life to an end.

A LONELY OUTPOST.

The tree from which the seed evidently came has furnished us with another source of interest, for every few years there appears at its foot that curious large fungus, Sparassis crispa, a mass about a foot wide and ten inches high, with the colour and much the appearance of a large bath sponge. It has been recognised by mycologists as a parasite on the root of Pinus sylvestris.—G. J.

[As another of the many examples of the peculiarities of plant distribution, this note and illustration are full of interest. Probably carried and deposited by a bird, or perchance by wind (pine seeds being adapted for this mode of distribution), it is astonishing how the seed germinated in such a compost of old mortar rubble and ultimately grew into a vigorous plant.—ED.]

CATCHING SLUGS.

SLUGS have been very troublesome in my garden of late. I have reduced their numbers to almost negligible proportions in this way: In the evening a number of large cabbage leaves are secured and, after slightly warming these, are spread with lard. The leaves are then placed on the soil with the larded side downwards. The positions selected are those close to attacked plants or where signs of slugs are evident. As early as possible in the morning the cabbage leaves are examined and large numbers of slugs are collected from them and destroyed. In fact, the slugs seem to prefer the greased cabbage leaves to anything else that grows in the garden. It is important that the lard should be unsalted; if there is only a small trace of salt the leaves will be left severely alone.—L. B.

SIMPLE GARDENING

ANTIRRHINUMS FOR EARLY FLOWERING.

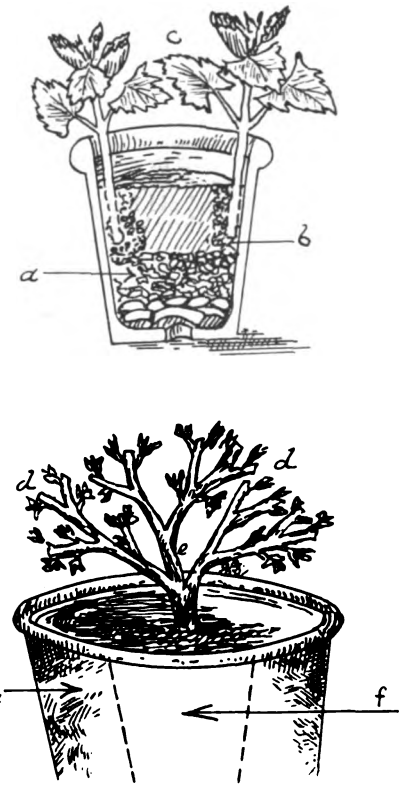
THE cultivator who wishes to have a very early display of these flowers should make a judicious selection of varieties. There is one that must be included in the list, as it is the most reliable of all, namely, Nelrose; the colour is a charming soft shade of pink; the habit of the plant is good, too. For ensuring variety of colour, the following should be included: Vermilion Brilliant, orange-vermilion; Amber Queen, canary-yellow, gold lip; Defiance, intense orange-flame colour; Golden Beauty, a rich golden yellow; and White Queen. The best effect with these plants is obtained by having few colours, but distinct, and many spikes of each. I always like to have a nice batch of them for early spring flowering. Recently, I grew as many as six hundred plants of Nelrose alone, in herring-boxes, twenty-four plants in a box, main flower spikes averaging 2ft. 6ins. in height. When these had been cut down, the plants were transplanted into an outside border, and continued to yield flowers all the summer and the following autumn, outside. The other sorts are not as suitable for such a prolonged display. Now, the plan to adopt is the following one. In July, sow the seeds in a box of good compost, outside, and duly transplant the resultant seedlings 2ins. apart, when small, in boxes. The final planting should be in large pots or boxes at about 4ins. apart. A thin layer of good rotted manure in the bottom and a little bone-meal, mixed with the remainder of the compost, will suffice. The plants should be kept in the open air till early in November.

PEACHES AND NECTARINES.

I am induced to refer to these fruits, especially those growing under glass, because of the great heat and its effect on the trees so grown, especially the old specimens. Several years ago, when we experienced a similar dry spell of weather, many old trees were killed. It is not necessary, and certainly not advisable, to keep the temperatures of the houses high, and the atmosphere dry, during such hot weather. Early in the season we do maintain a rather close atmosphere and keep out cold winds. But during the whole of the summer we should ventilate very freely indeed, opening the glass lights, and doors too, wide. The border soil should be saturated with water—not daily, but weekly, or every ten days—and, fortnightly, apply a good dose of diluted liquid manure. Except when the fruits are actually ripening, the trees should be syringed thoroughly, not merely sprinkled with water from a tiny syringe. Direct the water to the undersides of the leaves, using force. Twice each week, before syringing, lightly sprinkle soot on the border under the trees; and, once weekly, use liquid manure, rather strong, but in a small quantity. When the house is closed, or partly closed, the ammonia arising from the soot and manure will benefit the trees and help to keep down red spider. Nearly all the fruits of the later sorts have now hardened their stones and should be fully exposed to the sunshine. All shoots of the current year's growth should be tied in, approximately at a distance of 4ins. apart, as on these, next year, fruits will be borne.

FANCY AND SHOW PELARGONIUMS.

These are treated, in many ways, differently from zonal pelargoniums. Their season of flowering is restricted to spring and early summer, and I find many growers who like these plants do not know what to do with them after the flowers have faded. They have been described as dirty plants, on account of green aphides infesting them. Certainly the aphides like the plants, but their



foliage can be kept as clean as that of any other kind of plant by timely and adequate fumigation. At the end of June the plants present a rather seedy appearance and require special attention. They should be placed on their sides out in the open air and thoroughly syringed. Leave them so for a few weeks, then place the pots upright, prune back late in July or early in August, and insert the cuttings. If a very early flowering is required, prune earlier in July and insert cuttings, water the soil in the old pots and, when new shoots have made a very little growth, shake out the soil from the roots, reduce a few of the longest and re-pot the plants in small pots, to be shifted to larger ones in due course. Cold frame treatment should begin in September. Turfy loam, leaf-soil, rotted manure, bone-meal and sand will constitute a really good general compost. The letter *a* shows drainage; *b*, sand at base of cutting; *c*, cuttings inserted near side of pot; *d*, *d*, old cut-back plant; *e*, old plant beginning to grow again and its roots shaken out of old pot and re-potted in a smaller one, *f*, to be in due course re-potted in the larger size, *g*.

ENDIVES, LETTUCES AND RADISHES IN THE HOTTEST WEATHER.

Early in the springtime one wishes to trap as much sunshine as possible for the benefit of the above-named salad plants, with the exception of endive, which is, generally, raised later, from June onwards. At that time there is usually a good supply of moisture in the soil, and the latter remains moist for a considerable period. But now, one wishes to avoid such hot corners, as, unless they can be enclosed to retain moisture, the soil and situation will not prove conducive to quick, tender growth, so essential in regard to salad plants. A border facing north, north-east or north-west is an ideal one from June to the end of August, after which date we again seek all the sunshine possible to ensure, mainly, freedom from damping. The soil should be deeply dug and thoroughly broken up; those who can procure it should use rotted manure and mix it freely with the soil; or, sparingly, dry powdered fowl manure. If the latter be used, there should be 2ins. of manure-free soil on it, the roots of the plants will, in due course, penetrate to the manure and benefit. If these manures are not available, then use wood ashes and burnt soil very freely with the ordinary loam. I find such stimulants very valuable in promoting a quick and healthy growth. Seedlings, if overcrowded in such soils, will be almost useless, as radishes would run to top and lettuces and endive to very big leaves that would not withstand autumn damp and early frosts. The remedy is, then, to sow very thinly.

THE PLANT STOVE.

This structure is not as fully stocked at the present time as in former days, when many heat-loving subjects were very carefully grown. Well coloured crotons, dracænas and other plants are very effective, both in the stove and in groups arranged for effect, in the summer and early autumn. From the end of June to about the third week in August, fire heat is not required except on dull days and cold nights. If crotons are well syringed and kept in a high temperature with plenty of atmospheric moisture, especially at closing time in the afternoon, they will thrive and need not be heavily shaded, as the leaves are richer in colour than under dense shade. Caladiums also require plenty of moisture at their roots and in the atmosphere, but careful syringing and shading are necessary to prevent scorching of leaves. Coleus plants like sunshine, heat and moisture combined, coupled with judicious feeding. Cuttings of Panicum variegatum and Tradescantia zebrina, may be rooted very easily now in a sandy compost.

GEORGE GARNER.

Digitized by Google

GARDENING OF THE MONTH

FLOWER GARDEN.

ALYSSUM AND ARABIS.—Continue to propagate by means of cuttings.

ANNUALS.—Feed occasionally with liquid manure. Water and stake.

BROMPTON AND INTERMEDIATE STOCKS.—Sow now in open ground.

CAMPANULAS.—Sow in pans of light soil. Place in frames. Prick off into boxes when large enough and return to frames.

CHINA ASTERS.—Hoe well and give a light mulch of cow manure.

CHRYSANTHEMUMS.—Give a light dressing of artificials. Stake well and spray with insecticide to keep down plant lice.

HEUCHERA.—Propagate by cuttings. Insert them in frames containing sandy soil. Keep frames shaded and closed until rooted.

IRISES.—Give a top-dressing of loam, leaf-mould and 2oz. of superphosphate per barrowload. Water after application.

LAVENDER AND NEPETA.—Insert cuttings in frames. Water, close frames and leave until rooted.

POLYANTHUS.—Prick off seedlings into boxes.

ROSES.—Keep ramblers and climbers well tied in. Water and give liquid manure occasionally. Guard against mildew and, if seen, spray with 1oz. of potassium sulphide to 2 gallons of water. Bud briar stocks in showery weather.

SPRING BEDDING.—Prick out wallflowers, myosotis, etc., in showery weather. Sow more if necessary.

HARDY FRUIT.

APPLES AND PEARS.—Thin again if necessary. Summer prune. Pinch back side growths to six leaves. Keep down pests. Water if drought continues. Net dessert pears.

APRICOTS.—Keep well watered. Tie in leading shoots. Expose fruits to sun. Mulch and net trees if not already done.

CHERRIES.—Remove nets when early varieties have been gathered and cleanse trees with good insecticide. Syringe daily with soft water and do not let the borders become dry. Thin out shoots of Morellos.

CURRANTS.—When gathered thin out old shoots and encourage basal growths of black currants. Summer prune red currants.

FIGS.—Stop strong growths. Tie in leaders and thin out laterals to enable sun to reach the fruit. Give a light dressing of artificial manure if trees bearing a heavy crop. Water trees.

GOOSEBERRIES.—Mulch trees on light soil. Keep down pests. Shake off caterpillars of magpie moth.

LOGANBERRIES.—Tie up young canes temporarily. Thin out growths.

PLUMS, WALL.—Water well. Syringe forcibly under the leaves to check red spider.

RASPBERRIES.—Cut away old fruiting wood when crop gathered. Do not let the roots become dry. Tie in loosely the new canes. Reduce shoots of autumn-fruiting varieties by removing surplus suckers. Retain sufficient strong and healthy canes. Give the latter a mulch of well rotted manure.

STRAWBERRIES.—After fruiting, clean beds, remove decaying leaves and surplus runners, and lightly fork in some artificial manure. Layer other runners. Use 3in. or 4in. pots and a compost of three parts loam, one part sand and one part old mushroom manure. Peg runners into pots. Keep watered. Prepare site for new plantation, adding plenty of well rotted manure.

VINES.—Spray if mildew seen. Wash off the following morning with clear water.

PESTS.—Watch for and destroy eggs of lackey moth. Keep down woolly aphis, aphis and thrips by spraying.

VEGETABLES.

ASPARAGUS.—Thin out seedlings to 10ins. apart. Keep beds free from weeds. Give occasional soaking of water. Mulch beds with rotted manure.

BEET.—Hoe and weed beds. Make another sowing of globe beet.

CARROTS.—Hoe regularly. Make a sowing of stump-rooted carrots for a winter supply. Give a dusting of soot directly seedlings appear.

CAULIFLOWER.—Plant out late crop. Give plenty of water during dry weather.

CELERIAC.—Draw earth up round plants, and water.

CELERY.—Finish planting out late supplies. Keep well watered, and dust with soot twice weekly. Remove decaying leaves and give a loose tie round plant. Spray with paraffin emulsion to keep down celery fly.

COLEWORT.—Make another sowing for supplies during the winter.

CUCUMBERS IN FRAMES.—Syringe freely. Give liquid manure or artificials when several fruits set.

ENDIVE.—Make another sowing early in the month. Thin out early sowings and transplant seedlings.

FRENCH BEANS.—Sow a small quantity in vacant frames. Water during dry weather.

LEEKS.—Earth up, water and give occasional doses of liquid manure.

MARROWS.—Keep well thinned and watered. Pinch back laterals. Cut fruit when young. Feed with liquid manure.

MUSHROOMS.—Make up another bed in the open, selecting a shady position.

ONIONS.—Do not feed after first week. Dust with flowers of sulphur if mildew seen. Spray with paraffin emulsion to ward off onion fly.

PARSLEY.—Make another sowing and water well.

PEAS.—Draw a little soil up round seedlings. Mulch main crop. Clear away earlies and prepare ground for winter crop. Make a final sowing of Little Marvel or Excelsior.

POTATOES.—Lift early potatoes as soon as ready. Leave on ground for a few days before storing in a dark, cool shed. Prepare the vacant ground for winter greens and turnips. Spray main crop potatoes twice with Bordeaux mixture as a preventive against blight. Give final earthing up early in the month.

RUNNER BEANS.—Keep well mulched and supplied with water. Syringe in the evening to assist setting. Keep beans picked.

SALADS.—Make frequent sowings of lettuce, radishes, mustard and cress. Water frequently.

SEAKALE.—Remove flower-stalks.

SHALLOTS.—Lift when growth completed.

SPINACH.—Make a sowing of the prickly-seeded kind.

SPINACH BEET.—Sow for autumn supplies.

SPRING CABBAGE.—Select open site for making main sowing. Use Flower of Spring, April, Ellam's Early or Early Harbinger. Water drills before sowing. Dust with soot as soon as seedlings appear.

TOMATOES.—Keep side shoots pinched out. Stop plants as soon as four trusses of fruit set.

TURNIPS.—Sow Veitch's Red Globe for winter supplies.

WINTER GREENS.—Continue to plant out broccoli, kales, savoys, cabbage, etc., on vacant ground.

SHRUBS.

CLEMATIS.—Keep growths tied in. Do not allow roots to become dry.

FLOWERING SHRUBS.—Prune after blooming such shrubs as Veronica Traversii, deutzias, weigelias and some of the spiræas. Restrict growths, prevent overcrowding and unshapely bushes. Remove flower-heads of lilacs.

FORSYTHIAS, ESCALLONIAS, HELIANTHEMUMS, ETC.—Propagate by cuttings.

HEDGES.—Clip privet, hawthorn and holly. Fork base of hedges.

FLOWERS UNDER GLASS.

CALCEOLARIAS, HERBACEOUS.—Prick off seedlings now in pans. Use a light sifted compost.

CARNATIONS.—Pot on young perpetuals. Layer malmaisons in a close frame and admit air when rooted. Layer tree carnations and take some cuttings.

CHRYSANTHEMUMS.—Attend to tying. Feed with liquid manure and soot water. Give a top-dressing when roots appear on surface. Water twice daily. Syringe with insecticide to keep free from pests.

CINERARIAS.—Pot on into 3in. or 5in. pots according to size.

CYCLAMEN.—Shift young plants into flowering pots towards end of the month. Spray plants morning and night and shade from strong sun.

GLOXINIAS.—Pot on small plants into 6in. pots. Take leaf-cuttings.

HELIOTROPES.—Take cuttings. Insert in sandy soil.

HYDRANGEAS.—Remove flower trusses when flowering finished and stand outside in the open.

LILIUMS.—Stand L. longiflorum outside. Give top-dressing to others as roots appear on the surface.

PELARGONIUMS.—Take cuttings from stock plants. Insert in boxes of sandy compost and place in frames. Make firm and water, do not give much water until growth begins. Place winter-flowering plants outside on boards. Pinch off flower-buds.

PRIMULAS.—Pot on greenhouse kinds. Shade and keep cool.

SALVIA SPLENDENS.—Shift into flowering pots. Place in a frame and keep closed for one week.

SCHIZANTHUS.—At the end of the month sow a small quantity.

FRUIT AND VEGETABLES UNDER GLASS.

FIGS.—Spray trees not bearing fruit with liver of sulphur to keep red spider in check. Attend to pinching and thinning of shoots. Thin second crop fairly severely to ensure good ripe fruit in due season.

MELONS.—Give less water when ripening. On sunny days well ventilate melons in frames. Pinch new shoots to prevent overcrowding. Keep fruits off soil.

ORCHARD HOUSE.—Stand outside in sunny position trees which have finished bearing. Syringe with insecticide. Give frequent applications of liquid manure to apples and pears.

PEACHES AND NECTARINES.—Tie in growths retained. Pinch sub-laterals. Syringe forcibly under the leaves of late varieties to keep down red spider. Do not syringe when colouring. Expose fruits to sun. Ventilate well, leaving air on during the night. Keep down all pests, including ants.

VINES.—Give a drier atmosphere to those ripening. Leave top air on during the night. Remove any plants which are needing water from the vinery. Do not cut off too much foliage if berries splitting. Pinch young vines when they reach the top of the house.

CUCUMBERS.—Top-dress with equal parts of loam, leaf-mould and manure. Syringe well.

PARSLEY.—Sow thinly in frames for winter supply.

TOMATOES.—Pot June-sown seedlings into 3in. pots and place in a sunny position. Top-dress main crop. Pinch side growths regularly.

THE CROYDON FLOWER SHOW

RAIN was the order of the day at the annual show of the Croydon Horticultural Society, held on Wednesday, June 24th. With the exception of one or two years, this Society has always been unfortunate in having a wet day for its show. The attendance at the beginning was, in consequence, small; but as the weather improved, so, too, did the numbers of spectators. A large marquee contained the floral exhibits, and of these, roses were by far the largest class shown. Sweet peas and greenhouse plants were also well represented. There were smaller exhibits of perennials, foliage plants, carnations, violas, ferns, fruits and vegetables.

Many of the roses shown by amateurs were quite equal to those exhibited by trade growers, and it is both interesting and encouraging to see such perfect specimens from private gardens. Among twenty-four distinct varieties of roses for which Mr. A. Norman Rogers, Putney, received a first prize, were fine blooms of George Dickson, Captain Kilbee Stuart and Molly Bligh. Mme. Jules Gravereaux, shown by Mr. F. Slaughter of Steyning, was of excellent form; and nine blooms of the variety Gorgeous, exhibited by Mr. S. W. Burgess, were most attractive. Both Mr. H. L. Wettern of Oxted and Mr. S. W. Burgess carried off prizes in several of the rose classes. Mr. H. L. Wettern had excellent blooms of Irish Elegance, Red Letter Day and Jacques Vincent, arranged in vases; and Mr. S. W. Burgess showed perfect specimens of several varieties and a beautiful bloom of Miss Willmott. The Rev. F. R. Burnside also received several prizes for his roses, and in the class of twelve of distinct varieties he exhibited, among others, Avoca, Margaret Dickson Hamill and Ophelia. Mr. F. Ford also distinguished himself, and the varieties Mrs. E. J. Hudson and Gladys Holland helped him to win a first. Mrs. Foley Hobbs and Captain Oswald Fitzgerald, shown by Mr. F. G. Pocock of Warlingham, were very fine. Mr. A. H. Pullen and Mr. C. W. Edwards exhibited some very good roses of high quality.

Among the trade exhibits of roses, Messrs. Chaplin Brothers deserve great credit. Their new roses, Mrs. Herbert Nash and Lady Sydney Eardley Wilmot, together with the coppery orange of Lady Roundway and the bright scarlet-crimson of Red Star, made an effective group. In another section staged by this firm, Betty Uprichard, Lord Charlemont and Mabel Morse could be seen. Mr. J. H. Pemberton was showing many of his own seedling roses, and among them Anne, The Adjutant, Aurora and Ruth. Messrs. D. Prior and Messrs. G. Langley and Sons had prize exhibits, including many of the well known varieties; and among a group of forty-eight varieties shown by Messrs. Frank Cant and Co., Ethel Dickson, Mrs. Henry Morse, Golden Emblem, Lady Inchiquin and Gorgeous attracted attention.

Sweet peas were also a feature of the Show. Most excellent specimens were shown by Mr. F. W. Franks of Tonbridge and Mr. W. H. McAlpine of Nutfield. Their gardeners, Mr. W. Humphrey and Mr. F. C. Willie respectively, are to be congratulated on their excellent method of culture.

Messrs. Carters also were showing sweet peas, together with gloxinias, petunias, begonias and other greenhouse plants. Another meritorious trade exhibit of sweet peas was staged by Messrs, S. Bide and Sons, who were also exhibiting that useful and attractive shrub, Escallonia langleyensis. For their waved sweet peas this firm received a first prize. Mr. Thomas Butcher, the Court florist, had an exhibit of bouquets and wreaths.

A large group of delphiniums and hardy plants, staged by Mr. W. Wells, jun., added to the interest of the Show. Fine spikes of the delphiniums Amos Perry, Harry Smetham, Corry and Eva adorned the back of the stand. Papaver Mrs. Perry formed a charming patch of colour in the centre of the exhibit. Messrs. J. Cheal and Co. were showing some of their well known star dahlias as well as a few herbaceous perennials. Hardy perennials were also shown by several amateurs. Messrs. Smail and Co. exhibited alpines and perennials.

A trade exhibit of border carnations, including such varieties as Enid Lowe, Columbine, Loyalty, Mary Murray and Lieut. Shackleton, was staged by Mr. H. Lakeman. The plants looked exceedingly healthy and clean. The collection of gloxinias grown by Mr. J. Randall, gardener to Mr. F. Dyer, J.P., were much admired. The texture of the flowers and the glorious colouring are the results of good culture. A group of greenhouse plants and another of fuchsias from the same gardens were well staged. Mr. E. D. Morton (gardener, Mr. C. H. Fairs) entered for a number of classes, including exhibits of perennials, annuals, begonias, coleus and vegetables, and for several of these prizes were awarded. Many other amateurs had noteworthy exhibits of all kinds, but lack of space prevents any mention of them. On the whole, the vegetables were not up to exhibition standard, not so much in the quality thereof, but in the method of staging and dressing they fell short of the mark.

Lawn mowers, tools and various horticultural sundries were exhibited in the grounds outside by two firms, Messrs. L. H. Turtle and Messrs. E. W. and S. Rogers.

Such a successful show as this should do much to stimulate interest in horticultural matters in the Croydon district, and should also help to maintain the high standard of gardening now reached by many of the inhabitants of the neighbourhood.

THE KING said "That red Broom is certainly very striking."—(Chelsea Show, 1925).

New Hardy Crimson Broom

"DOROTHY WALPOLE."

A beautiful novelty for your own garden, and a welcome present to send your gardening friend.

Unanimous Award of Merit, R.H.S. (London).

First Class Siver Medal, Ghent International Show.

The richest in colour of any Broom yet seen—rich velvety crimson wings with rose-coloured standard. **It is as hardy, vigorous and free-flowering as Cytisus Andreanus.** Leading horticulturists describe the colour of "Dorothy Walpole" as far and away superior to Cytisus Dallimorei or any other Broom.

NET PRICES FOR IMMEDIATE DELIVERY (STOCK LIMITED.)

Strong pot-grown plants, **15/-** each.

Carriage paid rates to any station in Ireland or Great Britain:

One plant, carriage paid, for **17/6**; Two plants, carriage paid, for **33/6**; Three plants, carriage paid, for **48/6**; Six plants, carriage paid, for **94/6**

NET PRICES FOR AUTUMN DELIVERY.

Strong pot-grown plants, to flower next May, **12/6** each.

Carriage paid rates to any station in Ireland or Great Britain:

One plant, carriage paid, for **15/-**; Two plants, carriage paid, for **28/6**; Three plants, carriage paid, for **41/-**; Six plants, carriage paid, for **79/6**

Order your plants now. Supplies ran short last season.

"Lady N—— is delighted with the plant and thinks the colour absolutely beautiful."—June 16th, 1924.

"I am so delighted with the Broom 'Dorothy Walpole' that you sent me last year. It has done splendidly and is like a sparkling gem in the garden—one mass of flower."—Miss C—— B——, Dawlish, Devon. May 25th, 1925.

"Everyone who has seen my plant has been astonished at its warm, glowing red."—From a Vice-Chairman, Floral Committee, R.H.S. June 8th, 1924.

At Chelsea Show (1925) a well known millionaire said:—"Your Broom has done very well with me; the colour is far better in my garden than these plants you are showing here." (This is the experience of everyone who has seen it in flower where it has been grown. It abhors any covering and the colour always becomes duller after travelling closed up to a flower show.)

"Gardening Illustrated" Report of Chelsea Show, May 25th, 1925:—"W. Watson and Sons are showing a big group of their new Cytisus 'Dorothy Walpole,' a rich-coloured crimson and quite the best variety now for colour. They had a plant of C. Dallimorei to show the improved colour of 'Dorothy Walpole' and the contrast was very marked." (So marked is the improvement that the King asked if the plant of Dallimorei was a freak.)

"The Field," May 29th, 1924 (from the pen of an ex-Curator of Kew Gardens):—"The richest coloured Broom known is one named 'Dorothy Walpole.' It is as hardy as the common Broom . . . and it is very free flowering. . . . In the open air, and especially in sunlight, the colour is rich velvety crimson . . . more attractve than any of the coloured Brooms yet seen."

GLASSHOUSES

AT many of the gardens I visit, the deterioration both in the structure and in the use of glasshouses is constantly brought to my notice. Panes of glass will be missing, the woodwork will lack paint and some of the timber will be rotten; spans will sag, and the ventilating apparatus will squeak on rusty hinges and will, frequently, be unworkable. There is always one excuse for this deterioration, and that is economy; but is it always an economy to let a greenhouse fall into rack and ruin? As a rule, the structure of any well made glasshouse will last more than a lifetime, provided that a certain amount of care is taken to prevent deterioration going too far. An occasional renewal of timber, replacement of broken glass, and the free use of paint, are all that is required to keep a glasshouse in efficient repair: surely not a very heavy outlay! Many of the wrecks of glasshouses I have seen could have been saved if they had been taken in hand in time. But glass in a garden seems fated to be the first item in garden expenditure on which economy is practised.

The heating apparatus is a different question, for, although the structure has not altered very much in design during the last generation, greenhouse heating apparatus has improved out of all recognition, both in simplicity of design and in economical working. Hot-houses with old-fashioned heating are frequently inefficient and costly to run. There are two obvious remedies: one, to renew the heating and replace with new apparatus, such as is made by any reliable firm. This requires some outlay, but not so much as many people imagine. The other, and more economical, method is to run a glasshouse as a cold-house. Both methods have their advantages according to the use to which you wish to apply your glass.

This brings me to the point that few gardeners nowadays have any clear idea of how to run a glasshouse: they have no set plan in their mind at the beginning of the year of the uses to which it will be put during the coming season. It is used in a haphazard fashion, its capabilities are not tested, and much valuable space is too frequently lost. Part of this is due to the lack of foresight on the part of the gardener, part to the incorrigible habit some gardeners have of using a greenhouse as a hospital for sick plants, and part to misguided interference on the part of the owner, whose predilection for some particular plant makes him or her forget that a glasshouse is part and parcel of the whole garden and not a separate entity. When a garden is completely specialised or where a large amount of glass is kept, it is permissible to use a house for some specific purpose and for that alone, but in that case the gardener and owner realise its particular use and see that it is kept for that alone. But for the ordinary garden it is necessary not only to know its capabilities, but also its limitations. The same applies as much to a cold house as a house with heating. It is useless to imagine that you can fill a single house with vines or Paul Crampel geraniums and still use it successfully for all the numerous uses to which an intelligent gardener will wish to put it.

Too few people realise the possibilities of an old glasshouse, which can be used as a cold house so long as the structure is in a moderate state of repair. It can not only be used for general purposes or as a house for moderate forcing, but can be utilised for growing a multitude of that large band of plants which verge on the tender, usually by having their buds or young foliage cut by spring frosts. It can be used for rock plants, either in pots, as in the Alpine House at Kew, which is always so much admired during early spring, or after removing the staging and the piping, as an actual indoor rock garden, such as was described in THE GARDEN in the issue of February 16, 1924, page 91. It must be remembered that where the house is used as an actual garden, the soil in the beds does not get the same aeration and refreshment as soil out of doors, and so has to be renewed from time to time. With a little ingenuity, many successful uses can be found for a derelict house.

It is to be hoped, however, that, whatever use is made of a glasshouse, this entirely unnecessary idea of what is really a false economy is not adhered to. Whether you are an alpine enthusiast or a general gardener, an intelligent use of glass and a realisation of its possibilities will more than repay you. Most of all is a little thought necessary for its successful and economic running—what might be called co-operation between glasshouse, frame and general garden. They all fit into the general scheme of horticulture. E. H. M. C.

CREEPING PLANTS, by D. R. Lloyd Praeger.

DISEASES AND PESTS OF VEGETABLES—I, by George Garner

Digitized by Google

SOUTH AFRICAN GLADIOLI

IN THIS ARTICLE A FEW MEMBERS OF A BEAUTIFUL GENUS ARE DESCRIBED FROM PICTURES TAKEN IN THEIR NATIVE HABITAT. THE MAJORITY OF THESE SPECIES ARE, UNFORTUNATELY, EITHER EXTREMELY RARE OR NOT IN CULTIVATION IN THIS COUNTRY.

THAT the old order changes and gives place to new is well known, and one is reminded of this by the receipt of four photographs of South African plants from a correspondent of THE GARDEN, as they bring to mind the popularity of South African—or Cape plants, as they were generally called—in our gardens many years ago. And in this respect it is interesting to consider how the fashion in garden plants changes from time to time, for in spite of the great and universal popularity of gardening in this country at the present day, it is to a great extent confined to the cultivation of showy, decorative plants that will give a quick return. This is especially true of indoor gardening, and at the present day very little interest is taken in the many beautiful stove and greenhouse plants that were at one time so popular. In the case of the former this is somewhat understandable, as the war years and the present cost of fuel and labour have put them out of count; but in the case of greenhouse plants this does not apply to the same extent, for in most private establishments there are houses that might be used for the cultivation of many South African plants that require very little heat. And it is a matter of regret that the many beautiful South African heaths and bulbous plants are more or less lost to cultivation. True it is that the ericas and many of the bulbous plants require skilled cultivators, and at present those who have any knowledge of this class of plants are few and far between, but it only requires an interest to be taken in these plants, and cultivators would soon be forthcoming, and the writer hopes that one day the many beautiful South African plants may regain some measure of their former popularity.

Fig. 1 —BABIANA PLICATA, THE BABOON ROOT, WITH BEAUTIFUL SCENTED LILAC BLUE FLOWERS.

But to return to the photographs. Fig. 1 shows Babiana plicata (Baviaantjes or Baboon Root), or Babianer, the Dutch for baboon, in reference to the bulbs being eaten by baboons. This species has lilac blue flowers which are beautifully scented and, in common with others, was at one time in cultivation in our gardens. B. plicata is figured in the *Botanical Magazine*, Tab. 576. Some seven or eight other species are figured in the same publication, including B. stricta, of which there are several varieties, such as the beautiful B. stricta var. rubro-cyanea, in which the upper half of the perianth is brilliant blue, and the lower half a rich crimson, the two colours forming a striking contrast.

Their cultivation is quite simple, as they succeed perfectly under the same cultural conditions as are afforded freesias; a cold frame or a cool greenhouse being all that is necessary for their well-being. In the south and west, at least, they may be grown outdoors, planted in dry, well drained borders at the foot of warm walls narrow borders in front of plant houses being well suited for this purpose. Several of the species are sweet scented, B. sambucina being described as elder-flower scented.

Gladiolus tristis (avond-blom or avond-blommetje), Fig. 4, shows this somewhat sober-coloured species, the yellowish perianth having the three upper segments minutely spotted all over with reddish-brown dots; it, however, compensates for its lack of colour in being deliciously scented at night. In this country it succeeds quite well planted in a warm, well drained border, especially in front of a warm wall, the corms, of course, being lifted and stored for the winter like other gladioli. It is still occasionally met with in cultivation.

There is a variety of G. tristis known as concolor, with pale yellow flowers, without any markings, as the name implies; this variety, crossed with G. cardinalis, is said to be the parent of the well known G. Colvilei. G. tristis is figured in the *Botanical Magazine*, Tab. 272, and the variety concolor, *Botanical Magazine*, Tab. 1,098.

Fig. 3 depicts a species of gladiolus known in South Africa as the "Painted Lady." This name seems to be applied to several species, as different writers refer to different species, varying, no doubt, in the different districts. Generally the name appears to be used with reference to species and their varieties having pale pink or flesh-coloured flowers with red markings. Thus one writer refers to G. debilis, others to G. angustus, G. hastatus and G. blandus, and no doubt there are other species to which the popular name is applied. G. blandus and several varieties, as well as most of the other species mentioned have been in cultivation and are figured in the *Botanical Magazine*.

In their native state the "Painted Ladies" are usually described as growing in light, sandy soil, especially near the sea, or on sunny slopes among bushes and other vegetation; under cultivation they can be grown in warm, sunny borders as indicated for G. tristis, or they may be grown in pots in a cool greenhouse, that is, if we can only obtain them.

Fig. 2 shows Gladiolus involutus, known as the "South African Bluebell." Here again, as in the case of the "Painted Lady," various writers refer to different species, one writer referring to G. spathaceus as the "Caledon Bluebell." According to O. Marloth, this is determined by the districts in which they grow, G. involutus being found in the George and Knysna districts, G. spathaceus in the Caledon, and G. Bolusii in the

Digitized by Google

Tulbagh districts. One writer, referring to the "Caledon Bluebell," states that it is, especially in the neighbourhood of towns, in danger of being exterminated, as it is largely collected for flower shows and decorative purposes, and too often they are not cut, but are pulled up by the roots. Fortunately, there is now some effort being made in South Africa to preserve the native flora.

It is suprising that these beautiful blue-flowered gladioli have never been introduced to cultivation, at least, I can find no mention of them, although G. gracilis (pale blue) and G. recurvus, with blue and yellow scented flowers, are both figured in the *Botanical Magazine*. All the blue-flowered species, as well as many others should prove of immense importance to the hybridist, especially when we consider what has resulted from the use of G. primulinus during recent years.

Returning to the blue-flowered species in the "Flora Capensis" and Baker's "Irideæ," G. involutus and G. spathaceus, are described as having pink flowers, while O. Marloth and other South African writers describe them as blue.

There are at least 140 to 150 species of gladioli, a few native of Europe, in the Mediterranean regions, and Orient, but the headquarters of the genus is in South Africa, over eighty species and varieties being described in the "Flora Capensis," while some eighty species and varieties are figured in the *Botanical Magazine*, no fewer than twelve being figured in Vols. XV and XVI; and out of ninety-one figures in this volume, no fewer than fifty-seven are South African or Cape plants. This will indicate how popular this class of plant was at that time.

It may be of some interest to give the original parents of our modern hybrid gladiolus. G. psittacinus and G. cardinalis are given as the parents of G. gandavensis, G. ramosus from G. cardinalis and G. oppositiflorus, G. Colvilei from G. tristis concolor and G. cardinalis, G. Lemoinei from G. gandavensis and G. purpureo-auratus, G. Childsii from G. Saundersii and G. gandavensis, while G. nanceianus resulted from crossing G. Lemoinei and G. Saundersii. From this it will be seen that very few species have been used in the production of the garden race, and one would imagine that the introduction of some of the beautiful South African species should prove of great value to the hybridist, apart from the fact that they are all so beautiful that they are worthy of a place in our gardens for their own individual grace and beauty.

HERBACEOUS FLOWERS

WHAT exactly do we mean by herbaceous flowers? The Oxford Dictionary does not help us very much to find an answer to this question. I suppose, strictly speaking, herbaceous flowers are those that do not make a woody stem—plants that spring up when the returning sun melts the snows of winter and die down again when the sad days of autumn return—in fact, plants that hibernate. There is something wonderfully fascinating in watching for the first shoots of herbaceous flowers to push through the bare ground. They are for the most part fine, old-fashioned flowers, such as one finds in cottage gardens. But one must not be too strict, a few annuals, a dwarf bush or two may be allowed to grow with them in the border. Somehow one always associates such flowers with a border. The combination "herbaceous border" seems to conjure up something quite definite to the mind of most gardeners. But there are many ways of making one. A friend of mine built himself a magnificent house and thought he must have a herbaceous border to finish off his garden. Not understanding anything about such things he had one designed for him. Before long a plan arrived, about a yard long, beautifully coloured like a jig-saw puzzle or a patchwork quilt, and on each little coloured space was a name most beautifully written. He was so bewildered, that he packed off his plan to a nurseryman and told him to send along the plants there indicated. In due course they came and he proceeded to plant his border "according to plan." That is one way of dealing with the problem. Another is to plant them just as they come, and some very strange effects one sometimes gets! I remember one case in particular in which a common peony got into the company of a scarlet Oriental poppy. The result can well be imagined. Year after year the two colours clashed and may still be doing so, for all I know to the contrary. To my way of thinking the setting is everything. A long border with a grass path along one side looks very well and is delightful in a kitchen garden. For those fortunate enough to have a garden enclosed with old red brick walls, a more suitable setting could not be found. Tall hollyhocks behind larkspurs and lupins in front of them, smaller things between them and a good border of, say, pinks or thrift, what more could possibly be desired?

Dark, closely clipped yew trees make a wonderful setting for delphiniums and the various colours of the lupins. But the yews must not be too near or their roots will draw all the nourishment from the soil and the plants will not present that vigorous, healthy look which is their chief characteristic. In planting herbaceous flowers it is of the utmost importance to know which are going to flower together, for on this depends the colour effects. For example, what could be more lovely than the tall, pink spikes of lupins against the gentian blue of anchusa. I like to separate my herbaceous plants into groups with an eye to these colour effects, which I can get from the use of quite ordinary plants in the garden, laying on my floral colour with a bold brush like an impressionist artist. The results have always been most satisfying to the eye. Behind come the stately hollyhocks, the single varieties being much more beautiful than the double kinds. Then there are the scabious, some of which are not truly herbaceous, being biennials or even annuals. They cannot be left out, however, they are so effective if massed together, all colours—blue, mauve, pink, white and maroon. A shady corner must be reserved for foxgloves, with wonderful dapplings and markings on the bells. They, too, are not truly herbaceous, but once in the garden they sow themselves and come up year by year. Later on come the Michaelmas daisies to brighten up the back of the borders. There are now some lovely varieties to choose from, a great advance on the older types.

THE APPEARANCE OF LUPINS IS CONSIDERABLY ENHANCED IN A SETTING OF EVERGREEN SHRUBS.

Need one do more than just mention the delphiniums, the kings of herbaceous flowers. They should not be dotted about, but planted in bold groups so as not to miss the effect of a mass of contrasting blues.

Then there are the lupins of every imaginable shade: blue, yellow, white, pink, mauve and violet. Of these there is an old legend, which tells how the Blessed Virgin on her flight into Egypt, rebuked them for making such a noise when trodden on, fearing they would thus attract the attention of Herod's soldiers to the whereabouts of her first-born. What could be more lovely than their rich green leaves after a shower, each with a little globule of water resting in the centre. We must not leave out the monkshoods; there are several varieties of them, all quite interesting. A dark violet one, flowering in May before the first lupin shows colour. Another comes much later on and is of a paler shade of blue. Some are yellow and some of two contrasting colours. They are rather despised by gardeners, beloved of the bees and of use to medicine, for from them is obtained the alkaloid, aconitine. Of spiræas there are several which are well worth a place in our herbaceous garden. Of them, perhaps, the best is the pink, though, personally, I am very fond of filipendula, with its great tufts of white flowers gracefully balanced on long, slender stems rising from a large rosette of fernlike leaves.

Scarlet lychnis and geums add a bright splash of colour to the middle of the beds, to which must be added the Oriental poppies, though the newer pink shades are more beautiful, if, perhaps, not quite so exciting. Then there are the peonies, who, so Maeterlinck tells us, "have drunk their imprudent fill of the sun, burst with enthusiasm and bend forward to meet the coming apoplexy." We should grow the newer kinds, however, not the old-fashioned red one which is so difficult to blend into any colour scheme. Of yellow herbaceous flowers there is the doronicum, in the early spring, and golden rod for the late autumn.

Another yellow composite with a wonderful rayed flower is Inula Oculus Christi, a name which has a fascination in itself apart from its supposed resemblance to the eye of Christ.

Another yellow flower which brings a pleasant gleam of sunshine into the garden in May is the Welsh poppy (Meconopsis cambrica). Of white and yellow daisies we have a large variety suitable for filling the gaps between the taller plants.

"Sweet William with his homely cottage smell," and the phloxes are two very useful plants which will brighten the

Digitized by Google

garden from June right on into the late autumn. When properly massed, with all the colours nicely mingled, these two flowers do much to add colour to the picture we are painting of the herbaceous garden.

We must have some "gold dusted snapdragons," and a few eschscholtzias to complete this picture, though neither are strictly herbaceous. Then there are the columbines, which derive their name from the Latin for a dove, from the fanciful resemblance of their flowers to a bevy of doves with their heads close together, as if in conversation.

Though the long spurred varieties are far and away the most beautiful, with their lovely contrasting colours of the most delicate shades, all columbines are worth growing, even the common wild kind.

In the foreground there are one or two other plants which deserve mention. Tradescantia, named after John Tradescant, who, in the seventeenth century, made a collection of flowers, which he gave to Elias Ashmole, who in turn presented them to the University of Oxford. This is the Virginian spiderwort, though cottagers call it the Widow's Tear, presumably from its purplish blue flower. It has only three petals, like its cousin in the greenhouse. Then there is the Bleeding Heart (Dicentra spectabilis), with its curiously shaped flowers, which are supposed to bear a resemblance to rosy-hued hearts.

Lungwort (pulmonaria), the blue and pink flowers of which are the first to open year by year, is worth a place in some shady corner, for the dark green foliage, splashed with white, which succeeds the flowers in June. Though this by no means exhausts the possibilities of herbaceous flowers, mention has been made of some of the best of them.

There are various ways of getting herbaceous plants. We can buy them from a nursery, we can obtain them by barter from our friends and we can raise them from seed. This last method, though it requires considerable patience, is by far the most interesting to the true gardener. There is a great fascination in watching for the first characteristic leaves to appear. Then we have the prolonged pleasure of seeing the plants getting larger and larger until they are fit to take their place in the herbaceous garden itself. Finally, there is the excitement of the first flowers. This is especially the case with the lupins and larkspurs, for, if it is mixed seed or seed we have saved ourselves, there is no telling what undreamt-of beauty is about to be revealed.

EDWARD CAHEN.

A FINE ORNAMENTAL TREE

DAVIDIA INVOLUCRATA is certainly, when carrying in spring its large, hanging, paper white bracts, one of the most striking trees in existence, quite distinct from anything we have been used to so far. A member of the family Cornaceæ, it was first noticed by Father David in 1869 on high elevations in Tibet. Twenty-eight years later, in 1897, Father Farges, a missionary in Szechuan, sent to the late Maurice de Vilmorin at Les Barres ten seeds. The inscription on the seed bag ran: "Davidia, grows in moist places; valuable seeds, requiring special care." Only one plant, still existing at Les Barres, arose from these seeds. In the years 1899–1902 Mr. Wilson, during his first expedition to China, was much impressed by the beauty of the tree and sent numerous seeds to the famous firm of Veitch, where thousands of seedlings were raised. This marked the introduction of the plant into the horticultural world.

Curious to relate, the decorative value of davidia does not seem, so far, to have been fully realised. True, glowing reports have been made repeatedly about it by those who had the good fortune to see this rare tree in its home, but it is nearly always only as isolated specimens that one meets it in dendrological or amateurs' collections. What if any bold gardener had had the idea of planting a whole avenue of it? The tree here represented, although the impression given is a very poor one indeed to anyone, like the writer, who has seen the plant in all its gorgeousness (many bracts had already fallen to the ground when the photograph was taken) gives some idea of what would have been the result. This is one of the first specimens sent out by the Coombe Wood Nurseries, planted some twenty years ago in a site that apparently suited it admirably, that is, moist and shaded from several directions by tall conifers. It now attains over 30ft. in height. The owner is Mr. Gerard, who spends all his spare time in his arboretum of La Fosse, near Vendôme, France. In May of this year the sight was truly unique. Thousands of bracts attaining as much as 8ins. long and 4ins. wide completely smothered the tree from top to bottom, waving right and left at the slightest gust of wind. This specimen is, I believe, one of the largest in existence in Europe. It had never, so far, flowered so profusely. On its upper part, unfortunately little noticeable in the illustration, owing to effects of light, there were certainly more bracts than leaves!

A FINE SPECIMEN OF DAVIDIA INVOLUCRATA OVER THIRTY FEET HIGH AT LA FOSSE ARBORETUM.

As is well known, modern botanists have divided the once monotypic genus of davidia into three species: D. involucrata, D. Vilmoriniana and D. læta, according to pubescence (absent or present) and colour (glaucous or yellowish) of the underside of the leaves. The specimen here figured answers to the description of D. Vilmoriniana. From the purely horticultural point of view, however, perhaps it is better not to complicate matters and to retain only the name of D. involucrata for all cases. As regards showiness and general appearance there is little difference between the plants.

Davidias like rich, deep soils, moist atmosphere and some shade. They are admittedly shy flowerers at first, but increase their flowering capacity considerably when a certain age and size have been attained. Their hardiness is complete, except perhaps in case of very late frosts, when young shoots can be scorched to a certain extent, a fact that rarely happens, however, for the tree starts rather late into growth in the spring. Now that seeds are produced close to nurseries and plants accordingly easily propagated (which was far from being the case some time ago), it is to be hoped that this most beautiful tree will find its way into gardens more and more where the soil and position prove favourable.

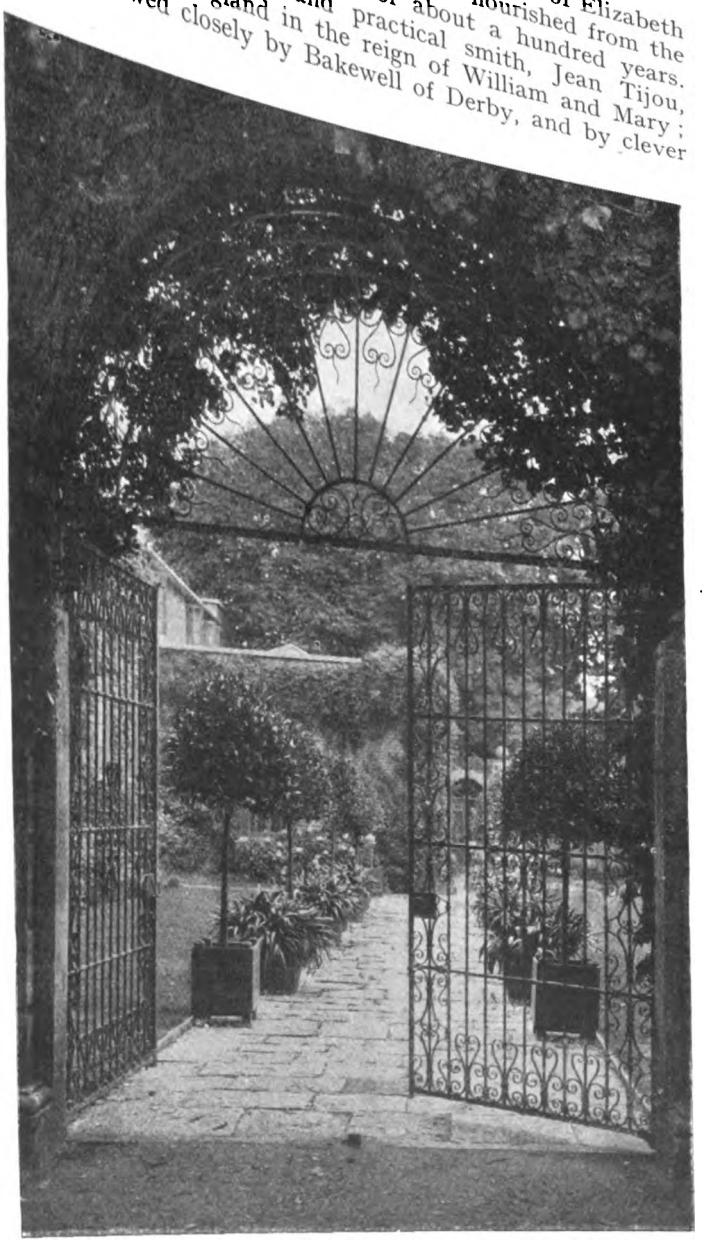
GARDEN GATES

BY GERTRUDE JEKYLL.

...ys are going up and ways of entrance ...onsidered, the possibility of a beautiful ...s often overlooked—this is an iron gate of ...rden design. Such a chance is lost when, as is so often ...es when the wooden doors. There may ...ught of wind may be injurious or where there is something ...unsightly that it is desirable to hide. Though in these notes it is only some simpler form of gate that is being considered, it is well to remember, and to see when occasion allows, any of the fine old gates that exist at the entrances of the grounds or gardens of our great houses, or such as are accessible to everybody at Hampton Court.

Iron gates were rare in England in the reigns of Elizabeth and James I, but the art of making them flourished from the end of the seventeenth century for about a hundred years. That wonderful designer and practical smith, Jean Tijou, was at work in England in the reign of William and Mary; he was followed closely by Bakewell of Derby, and by clever



A BEAUTIFUL THOUGH SIMPLE GATE IN THE ITALIAN STYLE.

smiths from Wales and the West Country, and a number domiciled in and about London. Some Italian gates were imported early in the eighteenth century. Their general design was quite different from that of the English smiths, for it was more free in line and was composed of much scrollwork, with a further enrichment of acanthus foliage and flower forms. There are examples of such work by the clever Welsh smiths, the brothers Roberts, who wrought in the earlier decades of the eighteenth ...ntury; but they never acquired, or possibly never attempted, the almost riotous freedom and sumptuous enrichment of the true Italian work.

The usual gate had a general filling of vertical bars; the filling thickened at the bottom with additional rods known as dog-bars. These served a double purpose: the practical one of keeping out dogs, and the other, of pleasing the eye by giving extra weight and solidity to the base of the gate. Then, at

A DESIGN WHICH, ALTHOUGH DECORATIVE AND ENHANCED BY THE PIERS, IS YET RESERVED.

convenient hand-height, came the lock rail, often with some filling of ornament, and also satisfying the eye with a distinct horizontal treatment at about one-third of the height; the remainder upward being of plain bars. In the more important gates there was a finely designed and wrought overthrow, with scrollwork, and the initials or some heraldic emblems of the owner. But in the simpler gates this was omitted altogether.

Where there are iron gates there should be brick or stone piers, if not of importance, at least of some size and solidity.

A FINE, STRAIGHT DESIGN IN IRONWORK.

Digitized by Google

In the finest examples they were of elaborate architecture with sunk panels or niches, and sometimes with a complete entablature. These would be surmounted by stone or leaden urns or heraldic beasts. In the case of the lesser type of gate the piers were commonly finished with stone balls.

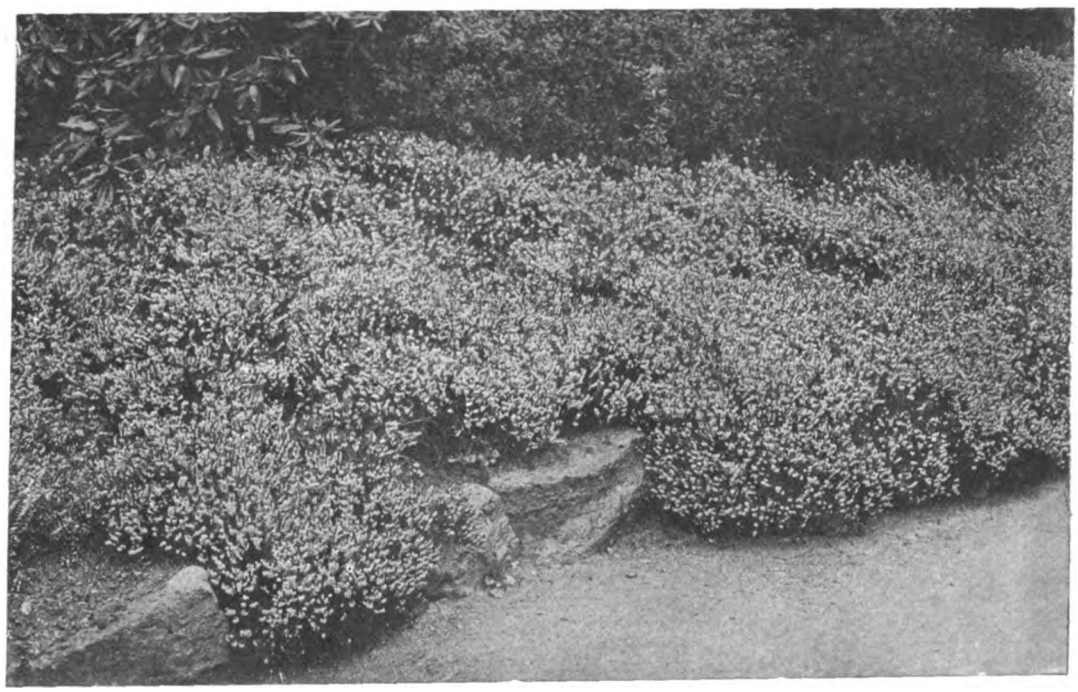
There are many places where really fine piers have become completely smothered with ivy or ampelopsis. If the gates and their piers have any merit, such overgrowth should never be allowed. This may be generally known now, but it is well to repeat the warning, because these rampant things grow quickly and, though they may have been cleared a few years ago, they may again be threatening to obscure good building. There is no reason to forbid any reasonable planting that may partly come over the piers, but it should be carefully watched and either guided or checked, as may be desirable.

Iron gates have to be painted. In our climate the most generally satisfactory colour is a dark grey inclining to a bluish tone. There is no harm in what is sold ready mixed as "dark slate," but it is the better for a fair admixture of dark blue. The French commonly paint their garden ironwork with red lead; it is good for the iron, but not pleasing to the eye. The pretty pale green with which they paint their garden tubs and seats is also unsuitable for iron, for which, at least in England, the dark blue-grey is much to be preferred.

SHRUBS FOR A SHADY ROCK GARDEN

FAR more recognition has been given of late years to the value of the shady slopes of the alpine garden and the many beauties that these display. Here we find numberless beautiful anemones, haberleas, mossy and encrusted saxifrages, ramondias, primulas, etc., flooding the slopes with a welter of beauty and colour over many months of the year. If, however, we miss our shrubs, the inevitable flat look is unavoidable and—perhaps without knowing why—we miss something that is essential to the completion of a really beautiful picture.

Happily, the range of subjects that may be included among our possible varieties is a fairly wide one—quite sufficient, at any rate, to obviate all chance of monotony. It is worth while noting, too, that the choice may be made to cover an equally wide range of soils, and those species that are most likely to succeed upon the particular soil in which you propose to plant should not be left out of consideration. For example, if you have a shaded peat bed, azaleas are worth special attention, though one must confine plantings to the right kinds. One may paint a whole slope in blazing glory in early summer by judiciously massing amœna, with its vivid rose crimson flowers; Hinodegiri, rising to 2½ft. with fiery red flowers; Maxwelli, vivid carmine red; occidentalis, white and very sweetly scented; and Yodogawa, semi-double and pale lavender pink. If these are indulged in in any quantity, the massing will become a somewhat expensive matter, but it is possible to produce superb effects by using a few plants in a concentrated area. Once planted such a grouping improves every year, especially where the beds are heavily dressed with leaf-mould each spring. It must not be forgotten that buds, although expanding in spring, are formed during the preceding summer, and therefore it is most important to see that the roots are never allowed to become dry.



AN EFFECTIVE DRIFT OF ERICA CARNEA, THE WINTER-FLOWERING HEATH.

Requiring precisely similar soil and cultural conditions, near relatives of the above, Rhododendrons præcox and ferrugineum are both splendid plants, and have the gift of appearing particularly fascinating as single specimens in the small garden. Where there is more sand in the peat a charming little shrub—so dwarf that it scarcely raises itself above the soil—is to hand in Sedum Lyonii. The foliage of this somewhat resembles the myrtle, and each stem terminates in a cluster of rosy white flowers. Owing to its extremely dwarf stature, the plant must, of course, be kept well forward, otherwise it will be entirely lost. Either on sandy loam or peat success will attend the planting of Daphne Mezereum, one of the first plants to break the winter by flowering. D. Cneorum, the garland flower, is quite a different plant, forming dwarf rounded bushes of dark green foliage smothered in spring with deliciously fragrant heads of pink flowers.

For splendid effects in any soil it would be difficult to excel Cotoneaster humifusa, the vivid brilliance of which is produced entirely by the berries. The growth is of the trailing order, resting almost flat on the ground, and the whole plant presents a most gorgeous colour picture in September and October when the leaves become scarlet and crimson and gold, the berries being brilliant red. Another charming little berried shrub that is not, however, to be distinguished by the word showy is Berberis dulcis nana, an evergreen bush producing yellow flowers very freely, these being succeeded by blue berries.

The partridge berry, Gaultheria procumbens, is extremely pretty for massed plantings in any shady spot where the soil consists of peat or leaf mould, and gives the effect of a carpet of blue green leaves over which are snow white flowers followed by fine crimson berries. Succeeding magnificently in any soil that is free from lime there are two species of erica that will flourish in shade or partial shade, the latter, of course, being preferable. Erica carnea may be obtained either in white or vivid rose, and both are splendidly effective massed according to the size of the garden. Erica vagans gives us still more variation in colour, for it may be procured in blush white, pure white, deep red and a so-called scarlet which means, as usual, a fairly good red.

SUMMER ROSE SHOW

the National great annual held at Regent's Although the threatening, indicated the and enthusiasm for The arrangements were committee, especially Mr. Secretary, is to be con-

and 4th. somewhat in and

interest and instruction, especially when dealing with some aspects of the clean and healthy cultivation of the rose.

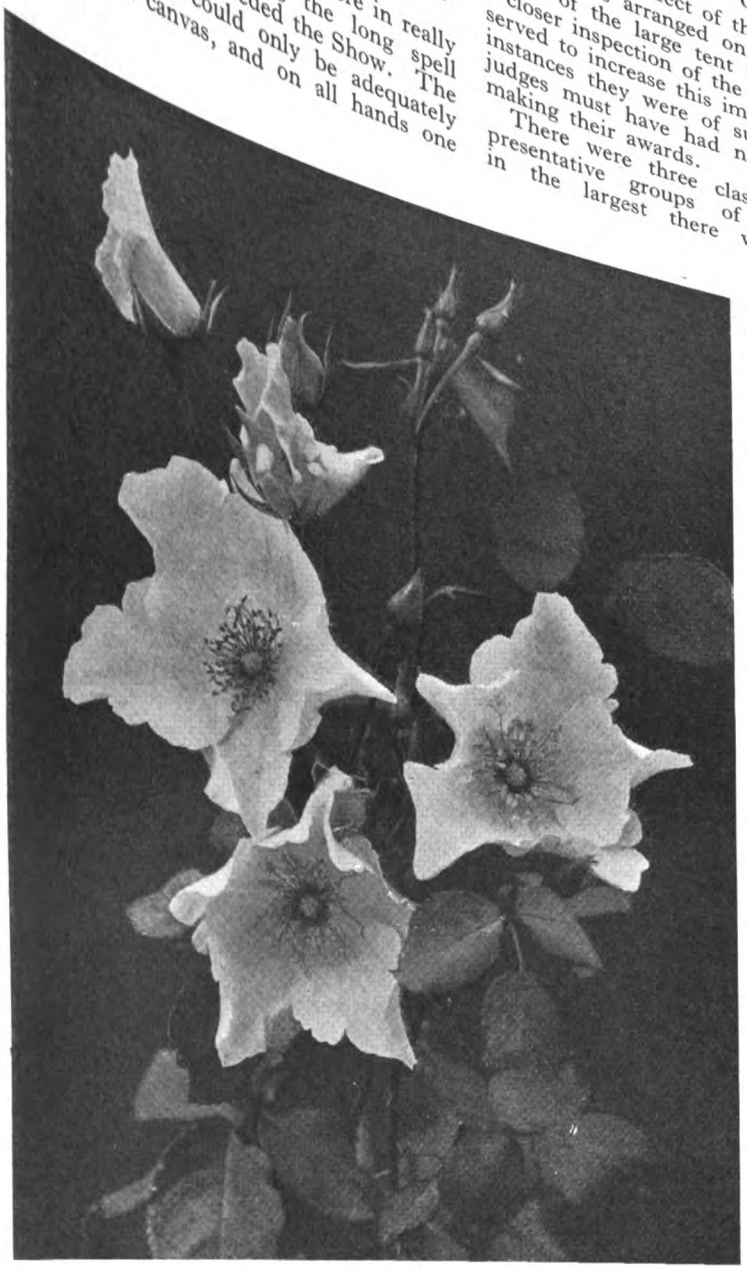
THE GROUPS OF ROSES.

The general effect of the generous groups of cut roses arranged on tabling along the centre of the large tent was excellent, and a closer inspection of the individual exhibits served to increase this impression. In most instances they were of such merit that the judges must have had no enviable task in making their awards.

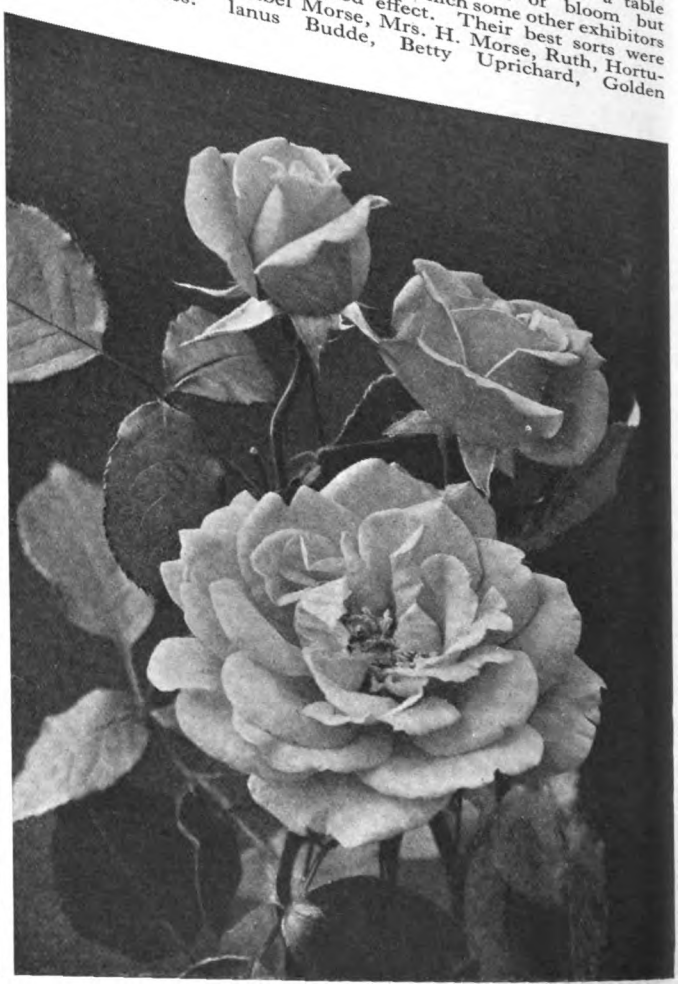
There were three classes for these representative groups of cut roses, and in the largest there were eight tables.

ment of linked pillars with baskets at the base, and the group was attractively edged with polyantha varieties. The baskets were filled with fine blooms of Lady Roundway, Lady Inchiquin, Mabel Morse and other sorts. Admirable groups were also arranged by Messrs. F. Cant and Co., Messrs. B. R. Cant and Sons and Mr. J. H. Pemberton.

There were four of the medium-sized tables, and here the first prize was awarded to Messrs. A. J. and C. Allen for a table which contained a wealth of bloom but lacked the edgings which some other exhibitors used to good effect. Their best sorts were Mabel Morse, Mrs. H. Morse, Ruth, Hortulanus Budde, Betty Uprichard, Golden



THE DEEP SHELL PINK BLOSSOMS OF DAINTY BESS.



SCARLET GLORY, AN EXCELLENT CRIMSON SCARLET SORT.

heard remarks of appreciation on the skill and patience shown in cultivation by the leading rose growers in the country. It is astonishing how, year after year, the flow of novelties is kept up, and this year is no exception. Many fine new varieties were staged, and it is somewhat difficult to discriminate between their individual merits. There can be no question that improvements in form, habit of growth, colour, fragrance and flower production have taken place rapidly within the last few years, and it is difficult to forecast what the future holds in store for us in this connection.

In addition to the main exhibits of roses, other flowering subjects in season, such as delphiniums, anemones, sweet peas, and carnations, were also staged. Another notable feature was the number of exhibits of sunries. Many of these exhibits were of great

The champion trophy was awarded to Mr. E. J. Hicks for an arrangement of pillars and large vases which displayed a great wealth of excellent bloom. The corner pillars were made up of Ophelia, Joanna Bridge, Mrs. H. Stevens and Climbing Golden Ophelia. The stands contained Los Angeles, Mabel Morse, Charles E. Shea, Mrs. E. Hudson, Betty Uprichard and other valuable sorts. The colour arrangement was excellent and the group was well finished. The chief feature of the second prize group was generous baskets of roses which Messrs. Alex. Dickson and Sons filled with Betty Uprichard, George H. Mackereth, Mrs. Wemyss Quin, Gwynne Carr, Mrs. Henry Morse, Golden Emblem, Shot Silk, Mrs. Henry Stevens and other admirable roses. The third prize was awarded to Messrs. Chaplin Brothers for a fascinating arrange-

Emblem and Souvenir. Messrs. Henry Morse and Sons, who were second, had linked pillars of Vesuvius, Etoile d'Holland, Betty Uprichard, Mrs. Henry Morse and Mabel Morse. Mr. Walter Easlea, who was third, had an uncommon and successful arrangement of pillars and small hanging baskets which made a graceful group.

The smaller group was so successful with exhibitors that the tables overflowed into an annexe. Mr. J. Mattock, who was first, had a charming arrangement of vases of Lady Inchiquin, Margaret Dickson Hamill, Betty Uprichard and Rev. F. Page-Roberts on stands rising above vases of Moonlight, Mabel Morse, Los Angeles and similar varieties. Messrs. Jarman and Co. were second with a table of Mrs. H. Morse, Paul's Scarlet Climber, Souvenir de Claudius Pernet, Lady Curzon and other

Digitized by Google

sorts. Mr. F. J. Edwards and Messrs. J. Jefferies and Sons were both awarded third prizes.

The A. C. Turner Cup, which is offered for a collection of thirty-six varieties, was won by Messrs. A. Warner and Son with an admirable exhibit in which Independence Day, Golden Emblem, Mrs. Henry Stevens, The Queen Alexandra Rose and Red Cross were prominent. Messrs. F. Cant and Co. were second with excellent vases of Padre, Archie Gray, Maud Cuming and Mrs. T. J. English. Mr. J. Mattock was third in this good class.

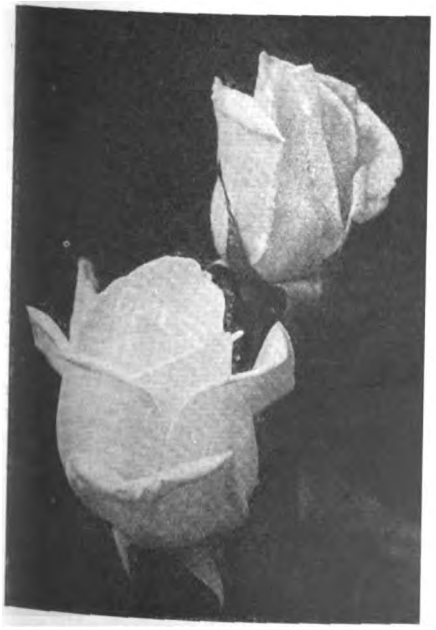
The best eighteen varieties of decorative roses were shown by Mr. G. Prince, who had admirable vases of Mrs. H. Stevens, Shot Silk, Souv. de Claudius Pernet and Betty Uprichard. Mr. F. Spooner, the second prize winner, showed K. of K., Innocence, Paul's Scarlet Climber and Isobel. Mr. G. Lilley was third.

EXHIBITION ROSES.

The championship trophy, which is offered for seventy-two distinct blooms of exhibition varieties, always induces a keen competition, and this year the trophy was won by Messrs. F. Cant and Co. with an admirable collection of good fresh blooms in which the colours were artistically arranged. The chief varieties were Dean Hole, Mildred Grant, Lady Ashtown, Clara Curtis, Medea, Admiration, Archie Gray, J. L. Mock and Mildred Grant. Messrs. B. R. Cant and Sons were a very good second, and they included excellent blooms of The Queen Alexandra Rose, Mabel Morse, Mabel Turner, Manifesto, Lady Inchiquin, Rev. F. Page Roberts and Nellie Parker. The third prize was won by Messrs. D. Prior and Son, who included a good new pink rose in Mrs. Murray Allison and also showed C. K. Douglas, Cleveland and Rev. F. Page Roberts of great merit.

The collections of thirty-two varieties in three blooms of each were mostly of high merit. Messrs. B. R. Cant and Sons were first, and they included trios of Rev. F. Page Roberts, Horace Vernet, George Dickson, A. Hartmann, Edith Cavell and Captain Kilbee Stuart. The second prize collection of Messrs. F. Cant and Co. was characterised by the high colour of many varieties, such as Mrs. Henry Morse, Mrs. G. Marriott, George Dickson, H. D. M. Baron, Ethel Dickson and Alex. Ernslie, which were admirable.

The China trophy, offered for forty-eight blooms, distinct, was won by Mr. C. Gregory,



THE LARGE OVAL FLOWERS OF MRS. BEATTY.

who included H. V. Machin, Mrs. Henry Bowles, J. B. Clark, Mabel Morse, Earl Haig and Mme. Jules Gravereaux in a praiseworthy exhibit. Messrs. Jarman and Co. were a close second, and their excellent collection included Premier, Joseph Welch, Mrs. Sam Ross and Freda. Mr. George Prince was third.

The first prize in the extra class for the above divisions was won by Mr. H. Drew, whose twenty-four fine blooms included Mrs. E. J. Hicks, Mabel Morse, Coronation, Edith Cavell and Mrs. H. R. Darlington. Mr. E. J. Hicks, the second prize winner, had good examples of Constance Soupert, Mrs. George Norwood, Maman Cochet, White Maman Cochet and Mabel Morse. Mr. G. Burch was a good third.

In the class for trios of eight varieties, the quality reached a high standard of excellence. Mr. George Prince, the first prize winner, included Mrs. George Marriott (of which one bloom was the silver medal tea rose), Mrs. C. Hall, H. V. Machin, Earl Haig and Ethel. Messrs. Jarman and Co. were third, and they included Mrs. C. Lamplough, Joseph Welsh, Mme. Jules Gravereaux and Mrs. C. Hobbs. Mr. H. Drew was third in this excellent class.

The tea and noisette roses were better than might have been expected. Messrs. C. Longley and Sons were first with eighteen fresh blooms of such sorts as The Bride, W. R. Smith, Molly Sharman Crawford and Mme. Jules Gravereaux. Mr. G. Prince won the second prize with large blooms of Maréchal Niel, Mme. Jules Gravereaux, Mrs. Foley Hobbs and Mrs. H. Taylor; while Messrs. D. Prior and Son were third.

The best twelve blooms of any new rose distributed since January, 1921, included Marcia Stanhope, Enid Charlemont and Mabel Morse, shown by Mr. J. Mattock. Mr. E. J. Hicks in his second prize collection included Lady Inchiquin, J. G. Glassford and W. Hordes.

The best twelve of any similar variety were vivid blooms of Captain Kilbee Stuart, shown by Messrs. D. Prior and Son. Marcia Stanhope, shown by Mr. H. Mattock, was second; and Lady Inchiquin, by Mr. G. Prince, was third.

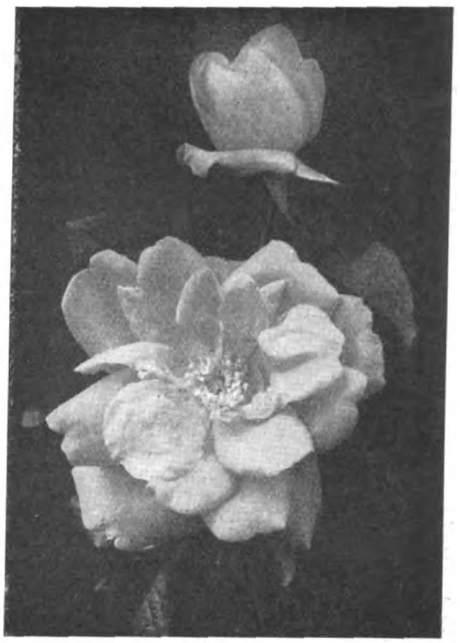
NEW AND NOTEWORTHY ROSES.

DAINTY BESS.—Probably the best hybrid tea single variety which was on show. The flowers are composed of beautiful crinkled and waved petals of a fine delicate pink shade, while a deeper shade is to be found on the reverse of the petals. It appears to be very floriferous and a fine contrast is provided by the foliage. It is certainly one of the best roses of the year. The flowers have a slight haunting fragrance. Awarded a gold medal. Shown by Mr. W. E. B. Archer, Ashford.

GWYNETH JONES.—This is certainly one of the most beautiful and decorative pernetiana varieties we have seen from the point of view of colour, which is unique. The flowers are semi-double, composed of petals of good texture and of a shade of fiery orange. It is indeed striking. The cluster of yellow anthers provides a vivid contrast in the flower itself, while these stand out from the bright green foliage. The flowers have a slight perfume. This variety received a gold medal. Shown by Messrs. McGredy and Son.

MRS. J. HEATH.—A good bushy hybrid tea variety bearing large-sized and pointed blooms. In the bud the colour is a mixture of orange crimson, but on expanding the petals become a shade of yellow tinged with red, the centre becoming deep yellow. It should prove a fine all-round variety. Shown by Messrs. McGredy and Son.

LADY F. STRONGE.—Another variety in hybrid teas of unique colouring. The large, well formed blooms are reddish to violet rose colour, shading to yellow at the base of the petals, which are of good size and



THE HANDSOME BLOOMS OF GWYNETH JONES, A GOLD MEDAL VARIETY.

substance. Shown by Messrs. McGredy and Son.

CECIL.—A fine pernetiana variety carrying large single flowers with spreading petals of a light yellow shade with a central cluster of deeper yellow headed stamens. Shown by Messrs. B. R. Cant and Sons.

MRS. BEATTY.—An excellent hybrid tea bearing large, handsome, long, oval-pointed blossoms of perfect shape. The petals are of good substance and of a shade of delicate lemon yellow, which is all the more striking against the dark glossy green foliage. Awarded a gold medal. Shown by Messrs. B. R. Cant and Sons.

RICHARD E. WEST.—Splendid flowers of a good yellow colour characterise this hybrid tea variety. The petals are markedly reflexed. Shown by Messrs. Alex. Dickson, Limited.

SCARLET GLORY.—An admirable hybrid tea variety carrying medium-sized blossoms of a good crimson scarlet colour. The petals are of velvety substance. The colour has the tendency of all crimson varieties, although not marked to any degree, to turn slightly blue on the margins of the petals. The flowers are also well scented. Shown by Messrs. Alex. Dickson, Limited.

GEORGE H. MACKERETH.—A very good crimson hybrid tea, carrying blooms which are sweetly fragrant. Shown by Messrs. Alex. Dickson, Limited.

DUCHESS OF YORK.—A fine decorative sort, bearing blooms of a wonderful colour. The centre is orange, shading outwards to pinkish and light yellow tones. Shown by Messrs. Alex. Dickson, Limited.

MRS. S. W. BURGESS. — A vigorous decorative hybrid tea variety with blooms of a cream orange colour, with a slight fragrance. Shown by Mr. S. W. Burgess, Tonbridge.

GOOILAND BEAUTY.—A cross between Golden Emblem and Sunburst, bearing blooms of a clear golden orange colour, which shades off to creamy yellow. The flowers are large and semi-double. Shown by Messrs. D. Prior.

KIRSTEN POULSEN.—A single dwarf polyantha sort, carrying numerous flowers of a deep rose red colour. Shown by Messrs. D. Prior.

Owing to shortage of space, the amateur and artistic classes, along with further notes on new roses, have unavoidably been held over until our next issue.

SUMMER PESTS OF THE ROSE

THE novice on consulting his text-book on roses and their enemies may well be appalled at the many and diverse insects and fungi that are probably mentioned. Of fungus diseases there will probably be round about a dozen, while of insects the names are legion. But, luckily for his peace of mind, the great majority are only very occasional in their visits to cultivated roses and may be ignored.

Diseases fascinate the scientist, who is somewhat akin to collectors of plants in that he gloats over the number he can tabulate. It is well that insect and fungus attacks should be recorded, with, where possible, suggestions for combating them. But this should always be prefaced by a plain statement of their relative unimportance to the cultivator. This the National Rose Society very wisely does in its most valuable little book on "The Enemies of the Rose," and heartens the amateur by stating that he is likely to be seriously troubled by only grubs and caterpillars, green fly and mildew.

During last spring the infestations of green fly on roses and, indeed, on most hardy plants, were more serious than usual. But within the past week or so there has been a marked decrease in their numbers. For destroying and, what is more important, preventing green fly a very mild insecticide suffices. In fact, during the growing season any strong corrosive wash is likely to do serious harm to the bushes as well as kill the green fly. It is only necessary to use a solution of quassia chips and soft soap, or some similar wash, which will adhere to the aphides and choke the breathing pores. The quassia chips should be boiled for a considerable time. Some say for twelve hours, but this period can be materially shortened if the quassia chips are first soaked in cold water for a week or so. A recommended formula is 2½lb. of quassia chips and 1lb. of the best soft soap (do not procure a cheap type, as this will contain an excess of soda) to 25 gallons of water. The soft soap should be thoroughly dissolved in boiling water and well stirred into the quassia extract before being added to the bulk of the water. This is an effective and economical fluid, but for those who have neither the time nor inclination for preparing it there are such proprietary mixtures as "Abol," "Nico Soap" and "Compound Quassia Extract," which are advertised in THE GARDEN. For all purposes it is important to use exactly the recommended quantity of all prepared insecticides and fungicides.

Although not serious in its effects, the "cuckoo-spit" or "frog-hopper" is often a nuisance on rose bushes by reason of the unsightly froth-looking covering of the nymphs. The simplest method of clearing them is to syringe forcibly with clear water so as to remove the froth and then to spray with one of the insecticides above mentioned.

In some seasons the leaf-rolling sawfly is fairly prevalent, and in addition to rendering the bushes very unsightly, this insect is actively harmful, largely by preventing the leaves from exercising their proper functions. In this case the leaflets which contain the greyish larvæ are rolled up tightly and, once the pests have a hold, there is nothing for it but to hand-pick and to destroy the affected leaves. In the early stages of an attack it is well to spray with a nicotine wash immediately after the hand-picking of the affected leaves.

These are the most important of the sucking insects which are likely to trouble the rose grower, and while a few of the biting insects, such as the leaf-cutting bee, which bites out circular pieces of the foliage to form its nest, may disfigure the bushes, they are more annoying than harmful and rarely visit bushes that have been sprayed fairly regularly with a quassia extract, as this seems to render the leaves distasteful.

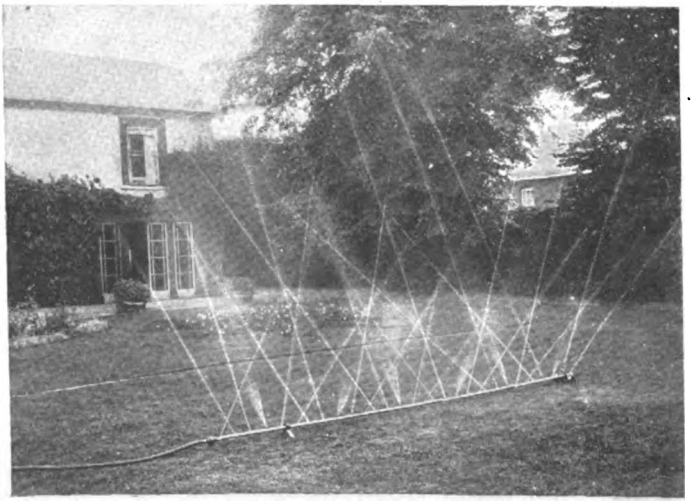
It must be clearly understood that one spraying alone is far from being likely to clear the roses of any pest. A suitable wash will kill the insects it touches, but some few are always missed, and there is the unborn generation to consider, so that the spraying should be repeated at short intervals. There are a few rules to be considered. Spraying should not be practised on sunny days or in the evenings of cold days. The first would be likely to result in scorched foliage and the second may cause a chill which would be very harmful to the roses.

Except for large areas, the spraying syringe such as is made by the leading firms is the best implement to apply the fluid with. The ordinary garden syringe, though admirable for its proper use, is unsuitable for applying an insecticide, as it is difficult to spray the undersides of the leaves and to obtain sufficient pressure to get a fine spray. It is always worth while to strain the wash before using it to make sure that it will pass through the sprayer without choking the jets. Where large areas have to be dealt with, a good knapsack sprayer such as the Mysto, Four Oaks or Stonehouse is admirable and easy to use.

With regard to fungoid diseases which attack roses, the present writer, being perhaps old-fashioned in some things, holds to the opinion that in many cases they are due to improper cultivation, and that where the roses are grown well fungoid diseases are mostly unknown. Mildew is an exception, and in many ways the rose grower is, with this, the victim of circumstances. As is well known, certain varieties are more liable to attacks of mildew than others, and in gardens which suffer from mildew it is always wise to grow only the more resistant varieties. As a preventive, "Kuremil" is excellent, or liver of sulphur dissolved at the rate of 1 oz. to 5 gallons of water, especially if a tablespoonful of liquid glue is added to make the spray adhere. A. C. B.

MECHANICAL AIDS TO IRRIGATION

THERE can be no doubt that one of the most important factors to be considered by the successful cultivator of practically all crops is the problem of providing a plentiful and sufficient supply of water during prolonged periods of hot and dry weather. While it must be admitted that, here in England, one seldom has cause to complain of extended droughts, it is, nevertheless, equally true that the growing seasons are few and far between when the rainfall and sunshine alternate in a sufficiently well balanced manner to render the lengthy and arduous task of artificial watering unnecessary. A few days of hot sunshine during the summer months cause the top spit of soil to become parched and dry very quickly, to the detriment of most seedlings and plants of a shallow rooted nature. Often such a state of affairs will result in serious damage to flower beds or lawns which have been the subject of much careful and tedious work in the past; while in the kitchen garden considerable delay will be caused before the crops reach maturity. The task of tending each individual



THE "WATERASQUARE" LAWN SPRINKLER IN ACTION.

Digitized by Google

bed or plant by means of a watering can is—in all but very small gardens—a laborious one, often taking up a great deal of time which could be profitably employed elsewhere, while the use of an

THE "GIANT" RAIN KING, WITH FOUR JETS AND MOUNTED ON A STAND.

ordinary plain hose-pipe cannot be regarded as a great deal more satisfactory. More often than not, the ground is saturated here and there in patches, and, unless great care is taken, the operator usually succeeds in getting more or less soaked himself.

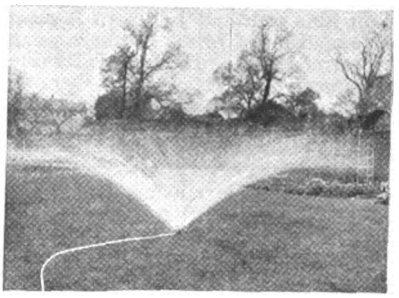
During recent years this problem has received a great deal of consideration from skilled engineers, with the result that it is now possible to obtain a great number of ingenious mechanical contrivances capable of distributing moisture over the ground in such an even and gentle manner that it closely approximates the actual fall of steady rain. The majority of these appliances can be obtained at moderate charges, and can usually be depended upon to give good service with an absolute minimum of labour involved. In most cases, it is only necessary to connect a hose-pipe to the instrument, turn on the water supply, and leave the rest to the machine. The initial cost is, of course, governed by the size and nature of the apparatus desired, and one can obtain small portable machines for dealing with lawns or gardens sectionally, or invest in a complete irrigation system which may be easily controlled by the manipulation of a valve.

For those who wish for a small but efficient machine at a very reasonable figure, either the "En Tout Cas" Pocket Sprinkler or the "2-Purpose" Rain King Sprinkler can be obtained. The former, which weighs only 1¾lb., will successfully cover with a fine mist-like spray a circle of 40ft. diameter, and the latter, while capable of covering the same area, has the twofold advantage of being readily convertible into a hose nozzle, in which case it can be quickly adjusted from a long, heavy spray with a range up to 55ft., to the finest mist. At the moment of writing, I have just received particulars of a similar machine of Canadian manufacture, known as the "Water Gun." It serves the combined purposes of a hose nozzle and lawn sprinkler, and appears to be a very serviceable little tool. It is fitted with a pointed spike which can be stuck into the ground at any desired angle, thus enabling it to be used for beds or borders of unusual shape, or for getting into obscure corners. By the simple turning of a small handle the supply can be regulated from a fine mist to a heavy stream, and quite apart from its use in the garden, it will be of great assistance in washing down outside windows, greenhouses, stone floors, etc. For those who wish to cover larger areas at one operation, an excellent choice remains, and the following brief descriptions of some of the better known makes will, perhaps, be of assistance in making a selection. The "En Tout Cas" Rotary Sprinkler is a very ingenious machine weighing only 7¼lb. As its name implies, it propels a jet of fine or coarse spray in a circular direction up to 80ft. in diameter. By a simple adjustment it can be made to oscillate backwards and forwards over a half-circle only, of the same diameter. It can be used in a variety of ways for watering lawns, flower beds or vegetables, and the water pressure required is only 12lb.

The "Stewart Rain King" is a very effective type of sprinkler which is so simple and sturdy in design that a child can manipulate it. It will cover an area of 70ft. on a pressure of 20lb. (which is about the usual house pressure) and can be instantly adjusted for either stationary or revolving operations. It weighs only 2¼lb., stands 5½ins. high, and has a base measuring only 6ins. by 5¾ins. A giant pattern of the same machine can also be obtained mounted on a standard and fitted with four revolving jets, instead of two as in the foregoing type. Each of these jets can be arranged to spray in different directions at once, and it is capable of covering a circle 90ft. in diameter. The "Pluviette" Standard is undoubtedly one of the

THE "EN TOUT CAS" ROTARY SPRINKLER ON A PERMANENT MOUNTING FOR SPRAYING BUSH FRUIT.

finest lawn sprinklers ever made. Working on a turbine principle, it will distribute a rain-like spray over an area between 300 and 400 sq. yds. from one centre. It is well adjusted for



THE "STEWART" RAIN KING AT WORK ON A LAWN.

varying water pressures, and is easily regulated to throw a fine, medium or coarse spray.

A more recent innovation of a slightly different nature has just been put on the market by that progressive firm, Messrs. British Overhead Irrigation, Limited. It is known as the "Waterasquare," and consists of a movable section of specially prepared pipe in 15ft. lengths. It is fitted at intervals of a few inches with nozzles set at different angles. Each length will, on an ordinary pressure of water, completely cover an area of 750 sq. ft. The total weight of the apparatus is only 42lb., and for convenience of shifting from place to place a small trolley is fixed at one end and the whole fitting can be pushed along in the same way as one wheels a barrow.

It is certainly one of the most effective methods for watering lawns and, in addition, is specially suitable for all kinds of sports grounds, such as bowling and golf greens, croquet lawns, etc., where a close and fresh green turf is desirable.

No article on irrigation would be complete without some reference to the great amount of experimental work which has been carried out by this firm, and it says much for the success of their endeavours when one finds their complete overhead systems being fitted on such eminent nurseries as Messrs. Carter's of Raynes Park, and Messrs. Sutton and Sons of Reading. The system has also been adopted by the London County Council on many of their public tennis grounds; while the number of market growers who have installations are far too numerous to mention. At their extensive demonstration grounds at Shepperton can be seen a site of 14 acres devoted to market produce. By means of the system fitted it is possible to spray every part of this ground with a supply of 20,000 gallons of water per hour, at the trifling cost of less than 2s.

Watering systems suitable for greenhouses, conservatories, lawns, gardens and orchards can also be inspected here, and any reader visiting these works can be assured of seeing demonstrations of a very practical and interesting nature.

THE AMATEUR SHOW

OPINION will probably be divided on this, the first Amateur Show, held under the auspices of the Royal Horticultural Society, at Vincent Square Hall on June 30th and July 1st. A comprehensive schedule of prizes had been arranged and it seemed that entries were fairly numerous in most of the classes; but there was a half-hearted atmosphere hanging over the Show, and for this the Society itself must, in part, be blamed. It would have been quite an easy matter to have re-arranged a number of the non-competitive exhibits so as to have filled the vacant spaces on the staging, and it should have been someone's duty to see that these collections, which were such an important feature of the Show, bore cards giving the names and addresses of the exhibitors.

Among the cut flowers competition was keen, especially in the case of sweet peas. Roses were not nearly so plentiful as might have been expected, even allowing for the drought, but the collections of general hardy shrubs were particularly interesting.

As we have suggested, the collections which were not for competition were admirable. Mr. W. B. Cranfield, East Lodge, Enfield Chase, deservedly received a gold medal for his collection of hardy ferns, which certainly could not be surpassed, even if it could be equalled. He filled the entire end of the Hall with well grown plants of a great many valuable and interesting varieties of scolopendrium (the hart's tongue fern), Athyrium Filix-fœmina (the lady fern), Polystichum angulare (the shield fern), Osmunda regale (the Royal fern), and many others.

Another unique collection was that of cotyledons, so attractively arranged by Mr. Reginald Cory, Duffryn, Cardiff. These ranged from species with large fleshy leaves to the smaller little clusters of almost sedum-like appearance. Sir Jeremiah Colman sent an admirable collection of his famous orchids from Gatton Park, as also did Mr. H. T. Pitt, Rosslyn, Stamford Hill. Hybrid liliums of great interest and such species as LL. giganteum, pardalinum, croceum, regale, Hansonii and umbellatum were displayed by Mr. R. O. Backhouse, Sutton Court, Hereford. A showy collection of Lychnis Haageana was there incognito.

A delightfully arranged collection of hardy flowering shrubs, sent by Colonel Messel, Nymans, Haywards Heath, included several varieties of leptospermum, cistus and escallonias, Indigofera Gerardiana and Philageria Veitchii, an interesting hybrid between Lapageria rosea and Philesia buxifolia. Mr. Lionel de Rothschild had a supplementary group of well grown shrubs similar to those in his first prize collection.

A large floor group, by Major Pam, Wormley Bury, Broxbourne, was arranged in the form of three water lily pools, surrounded by various sedges and grasses, bamboos, spiræas and Japanese irises, and this received much well deserved admiration.

COMPETITIVE CLASSES.

Roses were given the first place in the schedule, but it must be confessed that the blooms were generally somewhat disappointing. Although there were two classes for them, there was only one rather poor exhibit in the three vase class. The chief exhibits of tea and hybrid tea varieties were much better. The Rev. F. R. Burnside, a well known rosarian, won two first prizes with admirable blooms. His six vases included W. R. Smith, of lovely colouring, Dean Hole, Mélanie Soupert, White Maman Cochet and Mrs. Foley Hobbs, and his vases of hybrid perpetuals, Coronation, Louise Crette and Hugh Dickson were also of best quality. Another noted amateur rosarian, Mr. H. L. Wettern, Oxted Place, Oxted, was first in the class for twelve tea or hybrid tea varieties, and he included quite good examples of Avoca, Mrs. Wemyss Quin, Lady Inchiquin, George Dickson and La Champagne. Mr. G. A. Hammond, Silvercroft, Burgess Hill, who was second, had brilliant blooms of J. G. Glassford, Sunstar and Frances Gaunt, while in the third prize set of Mr. T. Evans, Reading, there was an enviable vase of Golden Emblem.

The general effect of the many spikes of delphiniums was good, though it would have been an improvement had more space been allowed. To the disappointment of some visitors, the two leading exhibits, which were put up by Mr. H. K. Farnell, The Elms, Acton Hill, and Mr. F. C. Stoop, West Hall, Byfleet, were composed of seedlings, but they were decidedly the best in the Show and were very attractive. Mr. E. H. Blakesley, Fairlawn, Redhill Common, had decidedly the best in the class of six vases, and he included Mrs. W. Wells, King of the Delphiniums and Lady Hammick. Mrs. G. M. Lewis, Sawyer, Brentwood, who won the second prize, showed two pretty vases of Madonna seedlings.

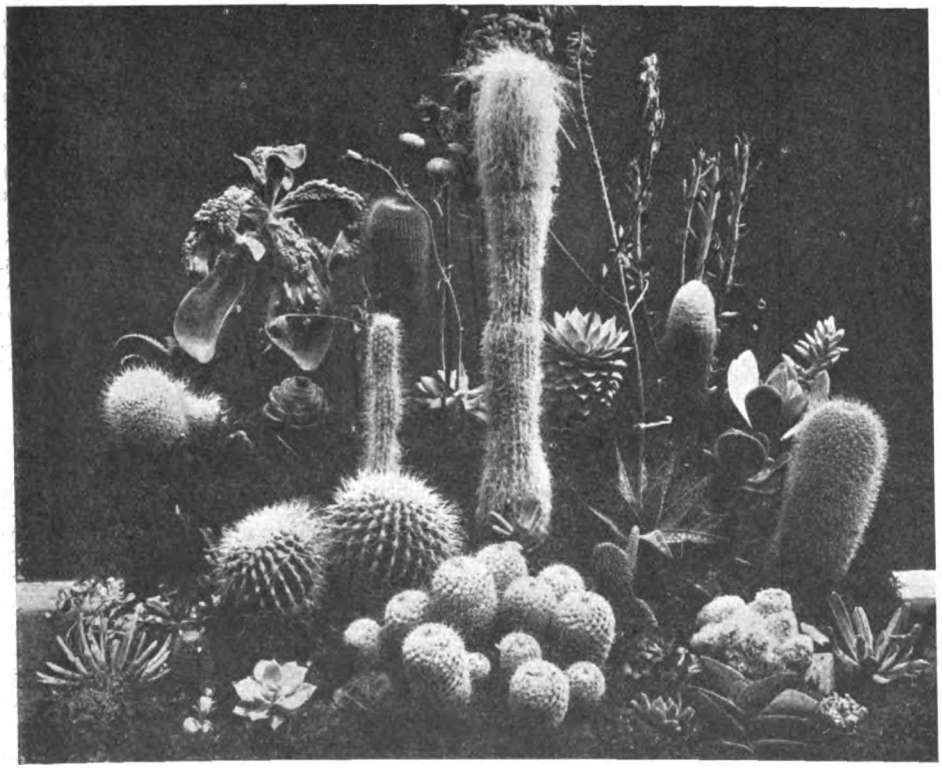
Sweet peas were certainly the most attractive flowers in the Show, and in excellent condition considering the trying season. The chief prize was awarded to Mr. R. W. Whitehead, Hillside, Reading, who had charming vases of Charity, Jean Ireland, Warrior, Orchid, Sunset and other good varieties. Mr. F. Churchward, Daccombe, Newton Abbot, was a good second, and he included glowing vases of Royal Sovereign and Tangerine Improved, two excellent orange coloured varieties, Mrs. Arnold Hitchcock and Wild Rose. Mrs. Hobart Tyler, Merton Court, Reading, had rather smaller blooms, but they were noteworthy for their intense colours.

Captain George Young, The Old House, Swallowfield, Berks, was first with six vases of very good sweet peas, which included W. J. Unwin, Grenadier, Warrior and Majestic, and Lieutenant-Colonel H. L. Scott, Hawthorn Lodge, Bracknell, was a close second. The best three vases were staged by Captain R. A. Barney, Faversham, who had lovely spikes of Charming, Powerscourt and Royal Scot. It was really too early for gladioli, but Mr. J. Fairlie, Acton, showed White Giant, Snow Wreath and Alice Kennedy very well and won the first prize.

Herbaceous flowers were of ordinary quality. Mr. Lionel de Rothschild, Exbury, Hants, was first and his most noteworthy vase was of Rhazya orientalis, an uncommon evergreen, introduced from Greece in 1889. It may be described as being an erect, narrow-leaved periwinkle, bearing plenty of small bright blue flowers, which it continues to produce for quite three months. In an unplaced collection there was a vase of Allium giganteum of striking appearance.

Carnations were well shown by Mr. R. Morton, Woodside Park, who was first with Linkman, Sam Weller, Mary Murray, Elaine and other good sorts, and in addition gained a first with three vases of border pinks. Mr. J. Fairlie was first with Border Yellow, Pasquin and Mrs. Hawksbee carnations. Violas were well shown by Mr. A. E. German, Hornchurch.

The new plant class was not very interesting. Mr. Lionel de Rothschild, won the gold medal with a large vase of Buddleia alternifolia, a Chinese species which was illustrated on November 8th last and which received an award of merit on June 27th, 1922. The long, slender sprays of fragrant, soft mauve flowers are very effective. The silver-gilt flora medal was won by Mr. F. C. Stern, with Indigofera amblyantha, a pretty rose coloured little shrub which unfortunately, droops when cut. The remaining exhibits were dormant rhododendrons.



THE ATTRACTIVE GROUP OF CACTI STAGED BY MR. REGINALD CORY.

Digitized by Google

FLOWERING SHRUBS.

Had the space been allotted more generously, the exhibits of flowering shrubs would have gained considerably in attraction. They were mostly of the "Riviera" type, which thrive best in the warmer parts of the country. Mr. Lionel de Rothschild, in his first prize collection showed a good dark form of Buddleia Colvilei, B. alternifolia, Leptospermum Boscawenii, Helichrysum rosmarinifolium, Zenobia pulverulenta and similar species. Lieutenant-Colonel Stephenson Clarke, Borde Hill, Cuckfield, included very floriferous branches of Leptospermum Nairnii, Abelia floribunda, Benthamia capitata and Magnolia parviflora. Sir William Lawrence, Burford Lodge, had a lovely vase of Rosa Moyesii, with Solanum crispum and Ononis fruticosa; and Mr. Reginald Cory, included the glowing orange-scarlet Lonicera Scarlet Trumpet, while some shrubby veronicas were conspicuous in the collection from Mr. F. C. Stern, Highdown, Goring-on-Sea.

PLANTS IN POTS.

A tasteful group composed chiefly of Lilium longiflorum, highly coloured crotons, spiræas, hydrangeas and palms, won the first prize for Mr. A. P. Brandt, Bletchley Castle, and Mr. C. Langmer, Ardgowan, Swallowfield, who used Cocos Weddelliana, crotons, caladiums, crassulas and gloxinias as effectively, was second. Mr. Brandt was also first with twelve plants, among which he had splendidly grown examples of Pandanus Veitchii, Aralia elegantissima, and a well coloured dracæna. Sir William Lawrence had such uncommon plants as Russelia Lemoinei and Zephyranthes carinata, a delightful rose-coloured zephyr flower, and a begonia with gorgeous foliage.

An especially fascinating little group of cacti was shown by Mr. Reginald Cory. There were little plants of Cereus senilis, C. Spachianus, Crassula puncata, Gasteria Bayfieldii, Mamillaria Parksoni and M. senilis.

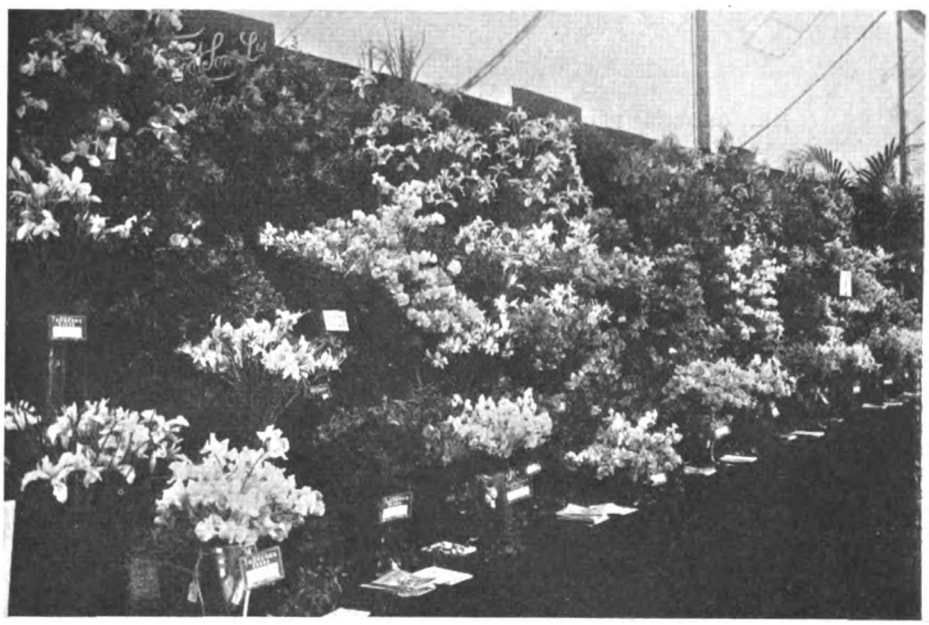
The orchids which won the first prize for Mr. H. T. Pitt, Rosslyn, Stamford Hill, included excellent miltonias, lælio-cattleyas and odontoglossums. Mr. A. Gentle, St. Albans, was second, and he showed Anguloa Clowesii, lycastes and lælio-cattleyas. In the class for six orchids, Mr. A. J. Sutton, was first with similar sorts.

Unfortunately, the remaining classes do not call for extended comment.

Gloxinias, mimulus, "any one genus of hardy plant," or British plants, were not represented, while the fuchsias and begonias were very ordinary. An exception was the six ferns in pots, where Mr. C. Henwood, Maida Vale, was first with charming specimens of Asplenium trichomanes trogyense, Blechnum spicant coronans, Polystichum angulare nitescens and other good examples.

BOURNEMOUTH FLORAL FÊTE

IN ideal surroundings and in glorious summer weather, a lavish display of flowers was provided for the public in the beautiful Meyrick Park on Tuesday and Wednesday, June 30th and July 1st. There was ample room on perfectly level ground for a big show of this kind, and the pine and heather clad hilly parts on the eastern boundary afford visitors a grand view of all open-air events. On the lower western side the large clumps of rhododendrons, pines and other kinds of trees cast a welcome shade of which the crowds of visitors took full advantage.



MESSRS. TOOGOOD S FINE EXHIBIT OF SWEET PEAS, GLADIOLI AND IRISES.

ROSES.

For a display of roses arranged for effect on a space 15ft. by 4ft., Mr. George Prince, Oxford, won the silver challenge cup presented by Mr. Walter Child Clark, and also the Bournemouth Corporation Cup, value 50 guineas, for the best exhibit in the competitive classes. Allan Chandler, a new pillar variety; Shot Silk, sweetly scented; Agéle Pernet, Mrs. Henry Morse, Mabel Morse, Mrs. Henry Bowles, Hadley, Queen Alexandra, Betty Uprichard, Sadie (a sport from Lady Pirrie) and William Cordes were prominent varieties. The exhibit was in the form of pillars with a groundwork of blooms in vases.

Mr. Elisha J. Hicks. Hurst, Twyford, Berkshire, was placed second, with a lovely collection in the form of pillars with a central arch and groundwork vases of blooms, including Queen Alexandra, Lady Hillingdon, Betty Uprichard, Chas. E. Shea and Mrs. Stevens, all in perfect condition. Mr. Arthur Radmore, Bournemouth, won third prize. In the class for twelve roses, distinct, on boards, Mr. George Prince won first honours. All were good, Edith Haig and Lady Barham being outstanding sorts. Messrs. F. Cant and Co., were second with blooms of Princess Victoria and Augustus Hartman. Mr. George Prince scored in the classes for five pink and five red, respectively; and Mr. Hicks in the class for five white. In another division, Mrs. A. Cook, Bournemouth, won first prizes for twelve roses, distinct, and also for six; Mr. H. Nixon was second.

SWEET PEAS.

Mr. A. E. Usher, gardener to Sir Randolf Baker, Bt., Ranston Park, Blandford, won the silver challenge cup for the third time, with a really grand lot of blooms tastefully displayed on a space 12ft. by 4ft. Grenadier, Wild Rose, Pink Perfection, R. F. Felton, Wembley, Mammoth and Purple Perfection were outstanding where all were good.

Mr. J. Stevenson staged a really magnificent lot of sweet peas; this collection was remarkable for the richness of the colours, these being deep, clear and very pure. Guinea Gold, Golden Glory, Coraline, La France, Diana, Venus, Charming, Crimson Glow and Stevenson's Cream, a green and yellow mixture, were notable.

Messrs. Toogood and Sons, Southampton, had a beautiful group of sweet peas and irises. Of the former, Doris, Floradale Purple, Matchless, Powerscourt, Mrs. Tom Jones and Royal Scot; and of the latter, Nymph, Prince Albert, Princess Dagmar, Grand Lilas, Lucinia, Bridesmaid and General Vetter, were very fine. The local classes for sweet peas were also well filled with charming blooms, Miss Fortescue, New Milton, Hampshire, being a prominent prize-winner.

CARNATIONS.

As with the roses and sweet peas, so with the carnations, there was a wealth of them. Messrs. Allwood Brothers staged a very fine collection in baskets and in vases. The silver cup, offered for the best exhibit in the Show, was awarded to this collection. A few of the many good varieties staged were the following: Beauty of Durham, Edward Allwood, White Pearl, Topsy (a better sort than Triumph), Laddie, Jessie Allwood (fine yellow), Mrs. H. Stoop and Eldora.

Messrs. Stuart Low and Co. also had a fine display, notable varieties being Amos Grove, Lord Lambourne and White Pearl.

For two vases of carnations, distinct, Mrs. Wyndham Pain (gardener Mr. P. Kitcher) won first place with very fine blooms of great substance and rich in colour.

HERBACEOUS FLOWERS.

These and rock plants were well represented. Messrs. M. Prichard and Sons had a charming group arranged in a natural manner on a space 100ft. square. Scabiosa caucasica, Watsonia Ardernei, kniphofia, Lupinus Downer's Delight, delphiniums Prichard's hybrid strain, Iris Duchess of Abercorn, I. Sultan, I. Haknoden (white), I. Lady Grey were the best.

Messrs. Skelton and Kirby also staged these plants well, Delphiniums Danube, Nettie and Violet Gueslin, and Aconitum Newbury Gem being notable.

MISCELLANEOUS EXHIBITS.

Mr. Usher won the challenge cup for a display of fruit, flowers and vegetables on a table space 12ft. by 4ft., all the produce being high class. Messrs. T. F. Rivers,

Digitized by Google

Sawbridgeworth, were represented, as usual, by healthy, well grown specimens of cherries, peaches, nectarines, plums, oranges and figs in full fruit in pots.

Messrs. Hilliers of Winchester had a charming exhibit of water lilies, bamboos, acers, gunneras and cistus; Cistus Silver Pink was conspicuous. Messrs. Stacey and Staddon were responsible for a rock and water garden, very natural and beautiful. Messrs. John Peed and Son, West Norwood, had a very imposing group of caladiums, crotons and gloxinias. Messrs. Leonards, Bournemouth, a unique exhibit of floral devices, cut flowers and choice fruits. Messrs. Jarman and Co., Chard, centaureas, irises, roses, gladioli, delphiniums and violas. Mr. T. K. Ingram, Parkstone, Dorset, floral devices. Mr. G. G. Collyer, Lymington, Hants, rock and herbaceous plants, Primula capitata, Campanula G. F. Wilson and Delphinium Loddon Guard. Messrs. Maxwell and Beale filled a large space with choice alpine and rock plants which were well arranged.

MR. GEORGE PRINCE'S EXCELLENT EXHIBIT OF ROSES.

Groups of shrubs and small specimens of conifers in pots were typical of the Evergreen Valley, as Bournemouth is called. Some of these choice shrubs and trees were exhibited by Messrs. Jeans and Trowbridge, who also won the silver challenge cup for a group of miscellaneous plants and cut flowers, arranged in a space of 200 sq. ft.—20ft. by 10ft. Graceful palms, a new zonal pelargonium—Mrs. Burt—coreopsis, blue hydrangeas, gaillardias, Canterbury bells and perennial asters were the principal plants and flowers in this group.

Gold Medals.—Messrs. Jarman and Co.; Messrs. Toogood and Sons (large gold); Mr. J. Stevenson; Mr. T. K. Ingram; Messrs. Allwood Brothers; Messrs. Stuart Low and Co.; Messrs. M. Prichard and Sons; Messrs. Leonards; Messrs. John Peed and Son; Messrs. Stacey and Staddon; Messrs. G. Watts and Sons; Messrs. Hillier; Messrs. T. Rivers and Son; Mr. Arthur Radmore; and Mr. W. E. Yandell.

Silver Medals.—Messrs. John Scott and Co.; Messrs. H. Haskins and Sons; Messrs. Skelton and Kirby; Mr. H. M. Elford; Messrs. Maxwell and Beale; Messrs. Jeans and Trowbridge; and Mr. G. G. Collyer.

CORRESPONDENCE

THE COLLECTION OF ALPINES.

SIR,—To visit during the summer months, in full flowering time, a strange mountain country, rich in plants one is anxious to acquire, is a very tantalising experience for an enthusiastic gardener. During a recent motor tour through the Cantabrian Alps and across the plains of Northern Spain, I saw many plants that I would have dearly loved to cultivate, but my efforts to transfer these to England met with very little success. If any of your readers can give me any "tips" that might be useful for my future guidance, I would be deeply grateful. It is all very well to say that the best way to introduce "alpines" is by means of seed, or to gather them in the autumn and pack them with dry roots! But how many of us can recognise the plants we want at this season? And, moreover, how seldom do we visit these mountainous districts during the autumn months?

From the small success I achieved, I feel convinced that it ought to be possible to devise some kind of zinc collecting box that would greatly facilitate the safe transport of "alpines," provided sufficient care had been exercised in the first instance in lifting them from the ground. Perhaps such a box already exists; if so, I would be very glad to learn from whom it may be purchased. I should imagine this box ought to be made of zinc or tin, and be at least 2ft. 6ins. long, 9ins. broad, and about 1ft. 6ins. in depth. The sides and lid, of course, would have to be freely perforated with holes to permit ample ventilation. With two trays divided into divisions of suitable size (also perforated), such a case should enable one to carry a fair number of plants (removed with a ball of earth), under airy, moist conditions; and if the divisions were lined with Fibrex or some similar substance, they could be removed at the end of the journey without any further root disturbance.

This box is, as yet, only a child of my fancy and before putting it to a test, I would like the opinion of others who have tried (I hope more successfully than myself), to lift and transplant "alpines" when in their full floral beauty.—COLLINGWOOD INGRAM.

VIBURNUM BITCHIUENSE.

SIR,—I was in the garden at Hayne, Moreton Hampstead, one day last month, and was struck by what seemed a giant bush of Viburnum Carlesii in the distance, in full bloom. When nearer, I discovered that, though the flowers and very pinky buds were very like those of V. Carlesii, the leaves were different and the flowers had no scent. I was told that it must have been planted many years ago, long before V. Carlesii was introduced. Another large shrub in full bloom, new to me, grew near it, with small, greenish-yellow, sweet-scented flowers. I sent bits of both off at once to Mr. E. A. Bowles and asked for the names, which he sent (in great hurry) as Viburnum Bitchiuense and Eleagnus multiflora, saying "the latter has pretty red fruit."—(Mrs.) LLOYD EDWARDS.

HABIT OF VIOLAS.

SIR,—I was sorry to see on the stands of some of the viola specialists at the recent Chelsea Show so large a proportion of the purely exhibition type of the flower. So many of these exhibition sorts are of little use as border or bedding plants, owing to their straggling habit of growth. They lack the tufted character which makes certain varieties so charming even before they come into bloom.

Visitors viewing an exhibit of violas at a show such as Chelsea make a selection as their fancy dictates, often regardless as to whether the varieties selected are useful for bedding and effect in the garden, for which purposes the average person requires these plants. Enquiries as to habit and reference to catalogue are apt to be overlooked when a particular variety is fancied. If a variety of poor habit is purchased, disappointment probably results, and the purchaser is likely to conclude that violas will not do well in his garden.

It behoves raisers of new varieties of violas to be careful in their quest for new and distinct sorts that the tufted habit and free-flowering propensity are not sacrificed on the altar of size. Having regard to the habit of many of the more recently introduced varieties, it seems evident that such a state of things may occur, and it seems to me that, in some cases at least, raisers are working on the wrong lines. Even those new varieties that are not actually straggling in habit are far too rampant in their growth. I have grown most of the named varieties that have been in commerce during the last twenty years and more, and for bedding purposes and freedom of flowering many of the older sorts are, for garden embellishment at any rate, still to be preferred to a great many of the newer sorts. It is only fair to say, however, that there have been sent out within recent years a certain number of most excellent varieties, distinct "breaks" in colour and of a good habit of growth.—H. C.

A WELL SET UP EXHIBIT.

SIR,—For some years I have been unable to attend shows, and am, therefore, the more dependent on what I see described and illustrated in the garden papers. I have always thought that in flower exhibits, and independently of the actual merit of the blooms, much depends on good arrangement. In your issue for May 23rd, among the notices of flowers at the Chelsea Show, there is an illustration of Messrs. Toogood's Spanish irises. The notice merely says that they are "well arranged," but these words do but scant justice to the quite admirable setting up of the exhibit, which certainly deserved special praise. The large central upstanding mass is perfectly balanced by the grouping of the blooms below, which swing up on either side in a way that is a model of good feeling for balance and proportion; while the back spaces on each side are just rightly filled by the slender upstanding chamærops.—G. JEKYLL.

NOTES FROM CONTRIBUTORS

THE DOUBLE DAISIES.

AMONG the flowers that have been very welcome this spring, particularly after the long drawn out winter, are the various forms of Bellis perennis.

The garden varieties of this daisy have been improved considerably during the past decade or so, and they can now be obtained in many tones of red and pink. They are all very hardy, will grow anywhere and are easily propagated by division.

Colonies of these plants interspersed among the low-growing subjects at the edge of the borders made my garden very gay for some weeks in spring. Although we are accustomed to look upon these daisies as commonplace little plants, they are well worth growing in considerable numbers to provide attractive masses of colour at a time when most needed.

Some very pleasing named varieties are Ball of Fire, a big flower, deep rich crimson in colour; Dresden China, a small flower of a delicate shade of rose pink—a charming little variety; Shirley, a recently introduced variety, the individual flowers of which are rather striking in appearance—it is a semi-double sort with dark crimson ray petals of considerable substance.—HOWARD H. CRANE.

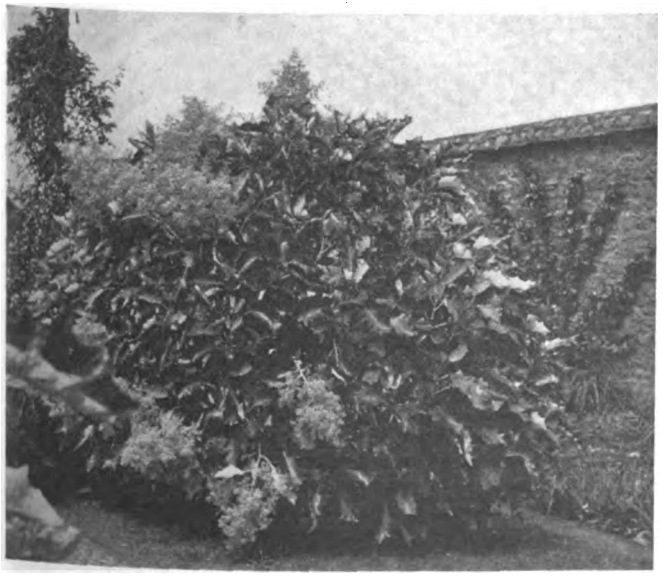
DAY LILIES.

WE can shut our eyes to the fugitive character of the day lilies—hemerocallises—when we recollect the output of their blossoms, and the comparatively little trouble the plants give once they have become established. They are never better served than when located near the margin of a stream, and are among the ideal plants for waterside gardening, loving moisture and, when catered for in this way, growing into beautiful clumps very soon. But it is not as waterside plants alone that they are useful, as one recognises their worth in the hardy plant border, and here they give a good account of themselves, if mulched with old manure from time to time. In July they are, with us, in full beauty, and have seldom failed through long years. H. flava, bright yellow; fulva, coppery red; aurantica major, orange yellow; and disticha fl. pl., semi-double orange crimson; are among the best known of these old-time garden flowers.—W. LINDERS LEA.

BRACHYGLOTTIS REPANDA.

I ENCLOSE a photograph of Brachyglottis repanda growing in this garden (West Porlock House, Somerset), which may interest the many readers of THE GARDEN. The measurements are about: Height, 6ft. 6ins.; circumference, 28ft. It was grown from a cutting struck five years ago.

It would be interesting to know if anyone has had like successful results with this composite.—G. W. W. BLATHWAYT.



A FINE BUSH OF BRACHYGLOTTIS REPANDA.

A HYBRID HEUCHERA.

THE enclosed is, I venture to think, rather a charming photograph of Heuchera Tiarelloides, the hybrid between a heuchera and Tiarella cordifolia, which seems to partake of the nature of both parents. I trust it may interest many readers of THE GARDEN.—R. HUDSON

HEUCHERA TIARELLOIDES, WHICH BEARS SOME RESEMBLANCE TO BOTH ITS PARENTS.

THE PURPLE CONE FLOWER.

FEW gardens of hardy flowers include among their treasures Echinacea purpurea, the purple cone-flower, a distinct and attractive as well as effective border plant, which would be a great acquisition to many places. It is far from being new to cultivation, but on account of a certain liability to succumb in very severe winters it has never been so popular as its attractions would justify. With regard to this remark about its being by no means a new plant, it may be pointed out that some confusion exists respecting the date of its introduction. In one work in my possession it is said to have been introduced in 1699, but in some others, generally considered reliable, it is stated as 1799. Seeing that it was figured or described in the *Botanical Magazine*, t. 2, published in March, 1786, and that reference is made there to what Miller said regarding its liability to succumb, it seems likely that the earlier date, given as 1699, is correct, although the *Botanical Magazine* gives no date itself. This point is probably of little importance to the gardener, but it would show how long this fine plant has been known in British gardens. It is frequently called Rudbeckia purpurea, but Britton and Brown refer to it, in the "Flora of the Northern United States and Canada," as Brauneria purpurea. Happily, the name of purple cone-flower is well established, although another is also applied to it in the United States, where it sometimes passes under the name of "Black Sampson," which is far from describing the flower's coloration.

The flower itself is a truly handsome one, with a distinct central cone and long, narrow petals of a good purple. It is faithfully represented as regards colour in the old plate of the *Botanical Magazine*, which tells us that the "outermost petals *x x* are long, purple and pendulous, and not unaptly resemble small pieces of red tape." It grows about three feet high and blooms from July to September, and in its best forms may well be accounted one of the most striking border plants of the season. It seldom ripens seeds with us still, but seeds produce plants which vary considerably in colour, breadth, and length of the ray florets. Good forms ought to be propagated by very careful division in spring, as later division is almost certain to be fatal to the plant. Some of the good forms are sold under varietal names and one of the best known to the writer is that called the "Taplow variety," crimson-purple, for which we have been indebted to Messrs Barr and Sons. The cultivation of E. purpurea is not difficult in ordinary garden loam, but it ought to be well drained, and one's own experience over a long series of years has confirmed the statement made by the old authors that it is liable to be lost in winter and that a spare plant or two should be kept in a frame to replace the others should they be killed. It is unfortunate that we have no absolutely hardy form of E. purpurea, which comes from Carolina and Virginia.—S. ARNOTT.

PUSCHKINIA SCILLOIDES.

A VERY useful spring-flowering bulb that is usually seen in large establishments is Puschkinia scilloides, sometimes named P. libanotica. A native of Asia Minor it has been known in this country for rather more than a hundred years and now forms a regular feature in any recognised collection of bulbs. The flowers, of which a dozen or more are borne on a spike, in a like manner to hyacinths, are of a very light blue and in some cases white colour with blue stripes. These marks or stripes are dark blue at the base, gradually shading off to a very light tone at the edges of the petals.

The flower spike attains a height of 6ins. or 7ins. and the flowering period with us is from the middle of March to the end of April.

The bulbs, which should be planted about 3ins. deep during the month of October are best left undisturbed for a period of three or four years, when they may be lifted, the young ones taken off and the whole of them allotted a fresh position. To get the best results the bulbs should be given a sunny position where the soil is light rather than heavy.—W. H., *Glasgow*

SIMPLE GARDENING

TOMATOES: TREATMENT OF SUMMER AND LATE AUTUMN CROPS.

A FEW years ago, when we experienced a very hot, dry summer, it was not much trouble to grow fine crops of tomatoes, even in the open air. Nearly all the fruits that set, ripened or were easily ripened after they were gathered. But we must not rely upon a similar warm autumn this year. The hot summer above referred to will be remembered as one favourable to the white fly, too. With reference to this pest I would urge amateurs, especially those who are growing tomatoes for the first time, to make good use of the remedies as supplied by advertisers in THE GARDEN. The tiny grubs are hatching out every day, and the remedies should be applied at least twice a week for a month or so till all flies are destroyed. When the plants have set several trusses of fruits, it frequently happens that the top trusses of flowers fail to set. This condition is caused by lack of strength of plant and frequently, too, through overdryness of the soil. While in full growth tomato plants require plenty of water, also top-dressings of rich lumpy turves and manure. Retain the leaves near the base in a healthy state as long as possible. It may be that a late autumn crop is desired. I always put out during July a batch of plants with this object in view, and select for them a nice sunny position near the glass. The plants may be finally planted in the border in large pots or boxes. When three trusses of fruits have set, remove the others, as the three will be burden enough for each plant.

PINKS AND CARNATIONS.

The pink is hardier than the carnation, it flowers early in the summer, forms dense masses in borders and is effective as an edging to a border. When the flowers have faded the silvery foliage is beautiful and retains this beauty and compact habit all through the year. The fragrance of the pink is rarely excelled by any other flower grown as a border plant. Divide the old plants or insert cuttings—pipings—to increase the stock. The present is a suitable time for the insertion of cuttings. Before any are taken from the parent plants see to the preparation of the border for their reception. This border should be in the open air, on the north side of a wall, low or of medium height; a narrow border in preference to one very wide. Dig the soil deeply and, if available, add some old potting soil to it, firm the ground and cover the surface with sand nearly 1in. deep, gritty, not fine and floury. As the cuttings are taken place them direct in a pail of water. The basal shoots are the best. Remove the three lower leaves, cut off square below a joint and insert at once, 2 ins. apart in rows, water through a fine-rosed watering-can, shade or, better still, cover temporarily with a garden frame. Border carnations should be layered as the basal shoots become available. First clear away all faded leaves and any weeds. Use as a compost, loam two-thirds, leaf-soil and sand one-third. Pack this compost close under the old plant. With a sharp knife cut, slant-wise, half through the stem. Bury the latter in the new soil and peg it firmly there. The chief after-attention is watering.

SOME CHRYSANTHEMUM PESTS.

Cultivators of these plants who wish to have in due course exhibition blooms will now anxiously watch the shoots that are to bear the flowers. There are several kinds of pests that destroy leaves and tender shoots. The leaf-mining grub is very troublesome this year. Watch the plants closely and directly any white specks and streaks

are observed in the leaves press the specks—which are grubs of the leaf-miner fly—between the thumb and finger. The letter *a* shows the sound leaf and *b*, *b*, *b*, grubs. Syringe the ashes round the pots with a paraffin emulsion and the foliage with clear, weak soot water every week to make the surroundings unpleasant for the fly. Green and black aphides infest the shoots as seen at *c*. Use tobacco powder in the evening and syringe it off early the following morning. While closely watching the plants note any suckers growing at the base, *d*, *d*, and remove them without injuring the roots of the plants. Do this till the middle of October. The cuckoo-spit or froth hopper is very prevalent this year, too. It surrounds itself with froth—the juices of the plant. The leaves, as shown at *g*, are deformed, and later on the shoots are eaten, shown at *e*, *e*, by the froth hopper or frog hopper, *f*, *f*. It is called the jumper, too. Destroy the larvæ now and, later, the jumpers by hand. These jumpers have broad heads and resemble frogs. If readers see little various-coloured, crocodile-like insects or grubs similar to the one shown at *h* on the shoots, retain them. They are the larva of the ladybird, a friendly insect which destroys aphides.

VEGETABLE MARROWS AND CUCUMBERS

I am now referring to vegetable marrows and cucumbers in the open air and also to cucumbers in cold frames. It is not always easy to succeed with these plants, and very difficult indeed in the case of marrows where the plants are growing on heaps of littery manure. There are two extremes to avoid, namely, the high, dry bed and the one under the spreading branches of large trees. In both cases there will be yellow embryo fruits and loss of crops. Where the plants are growing on the high, dry beds, improve the conditions by liberally top-dressing with good rich loam mixed with rotted manure. Where the plants are in much shade, train the shoots very thinly, stop the laterals one joint beyond the one bearing marrows and fertilise the young fruits daily. Cucumbers in open beds require very similar treatment, but the plants under glass must be watched closely, taking care that all tiny, useless shoots and fading leaves are regularly removed and strong side shoots bearing young fruits as regularly stopped to prevent undue crowding. Twice every day the plants should be well syringed, thoroughly wetting the under part of each leaf, or else the whole plant will be ruined by red spider in one week without hope of recovery.

EARLY CABBAGES AND ONIONS IN NORTHERN COUNTIES.

Where both kinds of vegetables are concerned, it is advisable to make two sowings of seeds, one about July 20th and the other about August 5th, in northern counties. Generally a small sowing in each case will be sufficient, and the resultant plants will be of more value than those from one big sowing made either early or late. In the meantime we must prepare the ground for these crops as long as possible beforehand. A very rich soil is not suitable, nor is a very poor one. The latter should be enriched with rotted manure if such is available. Of course, the border in which the seeds are sown will be a small one, and it should be in the open quarter, not sheltered by trees or buildings. Here, too, the soil should be deeply dug and well prepared, old lime rubble being mixed with it. The onions may be sown in the permanent bed—the one in which the bulbs are to mature—the surplus plants being drawn carefully and replanted early in October. The cabbages, too, should be planted in their permanent quarters between the middle of September and the same time in October, when the ground is in good condition.

IRISES FOR THE SMALL GARDEN

ALTHOUGH SPACE IN THE GARDEN MAY BE LIMITED, A CORNER SHOULD BE FOUND IN WHICH TO HOUSE A FEW REPRESENTATIVES OF THIS HANDSOME GENUS. IN FRONT OF SHRUBBERY PLANTINGS OR INCLUDED IN THE HERBACEOUS BORDER THEY LOOK MOST EFFECTIVE.

THE mentality that leads one to gardening is often fascinated by that widely diversified family of plants known as the irids. Into this Natural Order falls the iris, a genus that is represented, in one form or another, in, perhaps, as many gardens as any member of the floral world. But that representation is too often embodied in a few stray plants of the ill-named Iris germanica, which adds but a feeble quota of gaiety or colour to a garden, and that only for the briefest period in early summer.

BEARDED IRISES ALONG THE PATHSIDE.

IN SEMI-NATURAL GROUPS BEARDED IRISES ARE ALWAYS EFFECTIVE.

This is not an article for those deeply schooled in the iris as a genus; such folks would tell you how you may cull iris flowers right through the winter and early spring from the time of stylosa and histrioides till Delavayi closes the calendar in September or October. The purpose of these notes is rather to give a few common-sense hints on the culture of the tall bearded irises, which have become so popular during the last few years, and whose range of colouring has so widened under the care of the hybridist that these plants now form one of the most honoured and valuable occupants of our modern flower borders. One's interest in the iris grows with experience. A first planting of, perhaps, common and well known varieties fixes the attention on what are undoubtedly very beautiful flowers. Ambition soon begins to crave, and seductive catalogues are scanned, or selections made at the shows with a view to adding some choicer sorts at the next planting season. Insidiously and almost unconsciously a new hobby has been added to the joys of the garden, and a very pleasing and much valued one it becomes. But if one is bent on pursuing this hobby to its furthest possibilities, he is likely to have little reason for thinking of the iris as "the poor man's orchid." Six or seven guineas is not an uncommon price for a root of a new or recently introduced variety, and, while these are extreme and fancy prices, many of the newest additions to this iris group are undoubtedly of very high rank, and without excellence would never survive a false standard of price for more than one season.

The average grower will, of course, pay scant heed to those new things rejoicing in such highly polished prices, the more blithely as he knows there is wide enough choice at moderate, and even modest cost.

The bearded iris belongs to and is a typical example of that race of garden plants termed "thrifty." That is to say, it is easy to grow and is easily propagated. It would pay, therefore, to start a collection by obtaining even one plant each of, say, a dozen varieties, and from these increasing the stock as one's requirements or available space dictates.

Now, it is not an easy matter to give advice on the selection of a small number of sorts where a couple of hundred make insistent call for inclusion. Here, however, is a "baker's dozen" of standard well tried sorts, varied in colour, cheap in price, containing both tall and dwarf growers, all of good constitution and easy of increase, a very fitting collection for a small garden wherewith to whet the appetite for further adventures.

ALCAZAR.—This is a French variety raised about fifteen years ago, still in the front rank, finely upstanding in growth and flower-spike, and richly coloured. Standards blue violet with a faint suspicion of bronze, falls deep violet purple with distinct bronze veining at the haft.

ARCHEVEQUE.—Same origin as Alcazar and about the same time. A dwarf grower, extremely rich in colour. Standards violet purple of velvety texture; falls deep purple, flowers large and handsome.

AZURE.—A "Bliss" seedling introduced in 1918. Of all the many blue-toned irises, this is easily my first favourite among the cheaper sorts, the contrast between the standards and falls forming a perfect balance and giving in the mass a rich and telling effect. Standards lavender blue; falls deep violet blue.

Digitized by Google

CAMELOT (Bliss, 1918). —Tall-growing plant and the flowers are an excellent foil to the prevailing iris colours. Standards and falls are creamy white, delicately edged pale violet.

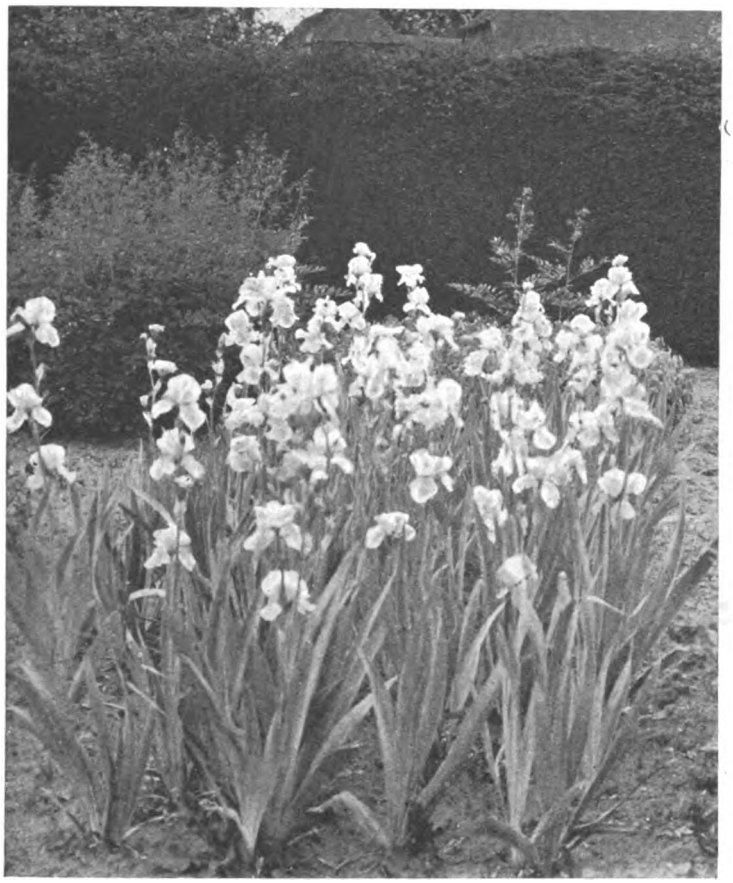
ELDORADO. — Another French introduction very attractive in its combination of colours. The standards are yellowish bronze with shading of heliotrope; falls bright purple with bronze yellow showing at the edges.

FRO.—A German iris, very free flowering and beautiful, medium height. The standards are bright golden yellow and the falls purple crimson slightly edged yellow.

LADY FOSTER.—Raised by Sir Michel Foster and introduced in 1913. Still one of the finest, the flowers being very large and of stout texture. The standards are pale violet blue, the falls darker in tone with a veining of old gold.

LORD OF JUNE.—One of Mr. Yeld's splendid introductions and has been in commerce some fourteen years. I think this is the most sweetly scented of all the irises, and its tall, commanding appearance and fine colour will ensure its selection in all gardens for a long time yet. Standards soft lavender blue; falls rich violet.

MARGARET MOOR (Bliss, 1918).—Standards and falls of this variety are both lilac red, the latter being deeper in tone. A valuable variant from the dominant blue tones.



THE STATELY IRIS PALLIDA DALMATICA.

PALLIDA DALMATICA (Princess Beatrice). — This wonderful iris has been in cultivation since the sixteenth century, and is still highly valued in the best collections. The foliage is vigorous, broad and glaucous, and the flowers stand high on strong upright stems. Both standards and falls are of beautiful pale lavender blue.

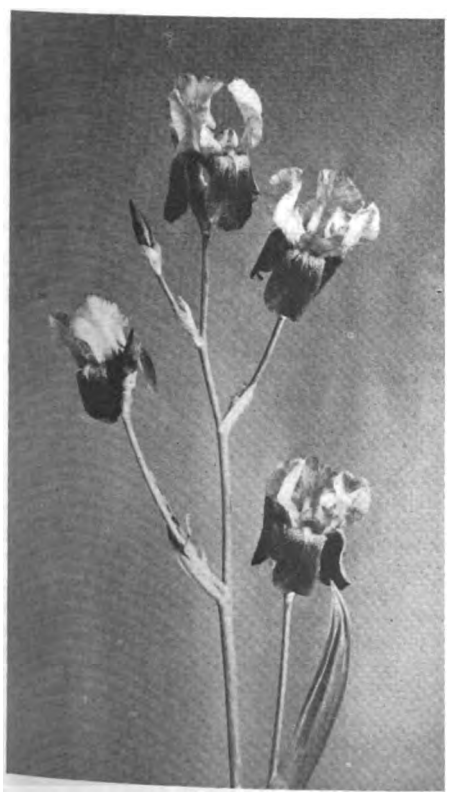
PROSPER LAUGIER. — A French improvement on the old Jacquesiana. Very floriferous and quickly forms bold clumps. The standards are a combination of brown heliotrope and bronze, and the falls deep violet crimson. A striking flower.

QUAKER LADY. — An American product very quaint and dainty in its tender colour scheme. Standards are smoky lavender suffused with yellow; falls similar, but deeper, with some violet flushing.

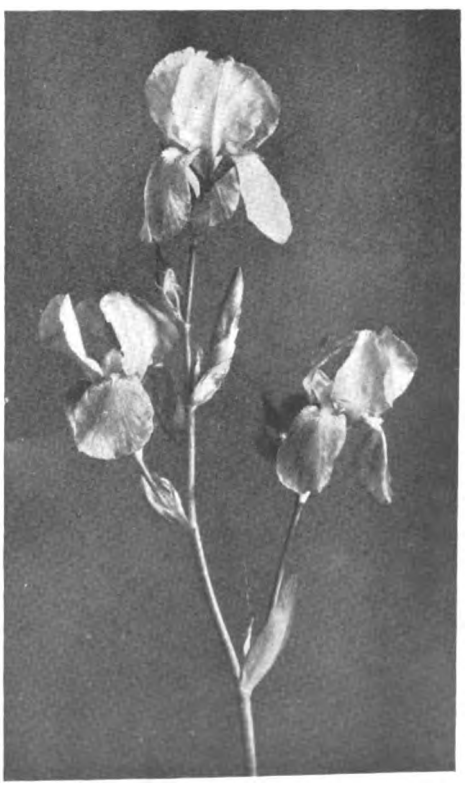
RODNEY. — Introduced in 1919 by Mr. Bliss, this is as near to a true self blue as we have. A tall branching stem throws the flowers well up, and these are of beautiful form as well as colour. A most desirable sort.

The culture of the bearded irises is simple, but frequently misunderstood. In conversation with garden-loving folk it is astonishing how often one is asked if these plants can be grown without the presence of a pond or stream. Evidently the conviction has got firmly embedded in the public mind that continual moisture is essential to their well-being. So far is this wrong that the Iris germanica race is one of the best drought resisters in our gardens. The plants are never in better condition than after a thoroughly dry period following the flowering season, and I can never remember seeing the foliage showing signs of distress for want of moisture. Even young seedlings three months old from germination will flourish happily in light soil during a long, hot, dry spell such as we have had this summer, and that without aid from artificial watering.

Nature's demand, then, is for a well drained soil, but it seems to matter little what the composition of that soil is. I have seen irises growing very contentedly in all sorts of mediums, from the lightest sandy loam to heavy clay. If there is any deficiency of lime in the soil, an annual dressing should be given and, if possible, a liberal quantity of crushed mortar rubble should be dug into heavy soils when beds are being prepared. The choice of a sunny aspect is another consideration making for their



THE GIANT ALCAZAR.



LADY FOSTER, A GOOD GARDEN VARIETY.

Digitized by Google

successful culture. Although irises will live and make an appearance of fairly healthy growth in shady or overhung quarters, they will only do really well in a position where they have free access to all the sunshine this island of "depressions" can get. Shallow planting must be adopted so that the upper part of the rhizome is quite exposed to sun and air.

The question of when to plant is an affair of extensive discussion. Some very successful growers declare September and October to be the best time, but my own experience, resulting from transplantations over the whole period from July to Christmas, tells me that the best results of all come from August operations, followed closely by those of early September, the latter being conspicuously better than those of late September and October. Yet I have received rhizomes, packed quite dry in a cardboard box, from the middle States of America just before Christmas, and they bloomed beautifully early in the June following. August and early September are, however, the periods I should choose had I full command of my time for planting at will. J. L. GIBSON.

IRIS SIBIRICA AND ITS ALLIES

BY W. R. DYKES.

MOST gardeners have heard of Iris sibirica even if they do not grow it, but comparatively few realise that it is only one of a number of species that form together a separate section of the genus. All come from Europe or Asia, with the single exception of the American I. prismatica, which is very distinct, but which seems, at any rate, more closely allied to the members of the sibirica group than to those of any other section of the genus.

All the members of the sibirica section like a cool, moist soil containing plenty of humus, and some will succeed where the roots penetrate below the water level in the soil, though they are also capable of doing well in a herbaceous border provided that the surface is mulched and manured. In my experience, divided plants never do so well as those which are put out as seedlings into their flowering positions and left undisturbed. There is, of course, the difficulty that seedlings of the different varieties do not come absolutely true from seeds, while even among seedlings of the species there is a certain amount of variation. When plants must be moved, or when it is desired to propagate by division a particular form or variety, the operation is best carried out either in early April when growth is just beginning or in September when the soil is usually moist and comparatively warm. If plants are moved in April, great care must be taken to keep the ground round them moist until they are completely re-established.

THE TALL AND HANDSOME IRIS SIBIRICA IN CONGENIAL SURROUNDINGS.

It is characteristic of the various members of the sibirica group that they form a more or less compact mass of slender rhizomes, from which grow a large number of roots, a great contrast to the somewhat sparse root fibres of the bearded irises. All the species except the Himalaya I. Clarkei and the American I. prismatica have more or less hollow stems, though in the case of some, such as I. chrysographes, the central cavity is nearly filled with pith.

I. sibirica itself seems to owe its name to a confusion with I. orientalis, because it appears to be a European species, and it is doubtful whether the true plant is found east of the Urals. It grows wild near the upper part of the Rhine, in Switzerland, Hungary and central Russia. The relatively small blue flowers stand high above the foliage on tall, slender stems, which are nearly twice as long as the leaves. I. orientalis has large flowers on shorter stems, which only raise them above the foliage, because the tips of the leaves bend over and droop. Of both species there are albino forms, that of I. orientalis being the well known Snow Queen, which is a purer white than that of the various varieties of I. sibirica, for the latter are more or less tinged or flushed with faint lilac or blue. Some forms of I. orientalis have their spathe valves heavily flushed with red purple, which has earned for them the name of sanguinea, though these red spathes are by no means a constant character.

Hybridisation between these two species produces interesting results, for the deep blue of the wild flowers can be diluted to a sky blue by crossing with the white, and the large flowers of orientalis can be obtained on the tall stems of sibirica.

Both I. sibirica and I. orientalis have their flowers heavily veined and flushed with deep blue purple on a white ground, which can, however, be changed to yellow by crossing them with I. Wilsonii, a yellow-flowered species from western China. The latter is not a very striking plant, for the yellow is pale in the somewhat twisted standards, and often dotted and flecked with purple on the falls.

I. Forrestii is another species from western China of more slender growth and narrow grassy foliage, but with flowers usually of a far clearer yellow and of more pleasing shape.

The most richly coloured species of the whole group is I. chrysographes, which earned its name, when I first saw it in flower, from the fact that its deep velvety purple falls are veined or streaked with gold over their central area. It comes from western China, where there appear to be several other closely related species or local forms. It is unfortunate that the various explorers, who since the beginning of the century have visited the great storehouse of good plants in western China, seem all to have been more interested in rhododendrons and other flowering shrubs than in anything so lowly as an iris. Consequently, we do not know as much as we might about this group of irises, and can only suspect that there are several good things yet to come into our gardens.

I. Bulleyana was first described as a wild species from the same region, but the variation among its seedlings casts some doubt on its claim to specific rank. It grows about 2ft. high, with somewhat narrow leaves and has flowers veined and blotched with blue on a white ground.

Digitized by Google

One of the tallest of all irises, and one that is valuable for its habit of flowering late in June, is I. Delavayi with long, drooping falls, on the central area of which appear large white blotches amid the surrounding purple. The first introduction of this species brought a form with dark red purple flowers, but later on some seeds, which were, I believe, collected by Mr. E. H. Wilson, gave me a whole series of colour forms, ranging through blue, as well as red, purple. A very pretty hybrid can be made by crossing I. Delavayi with I. Forresti or I. Wilsoni, for then the white ground of the falls becomes yellow.

The Himalayan I. Clarkei, from the neighbourhood of Darjeeling and the Chumbi Valley, is distinguished by the polished upper surface of its foliage and by its solid and not hollow stem. There is also extraordinary variation among the flowers, both in the shade of purple colour and in the markings and blotches on the falls. The stem also branches low down and often more than once, so that this species is abundantly distinct from the others in the group.

I. prismatica, from the north-eastern United States, has flowers like those of a small I. sibirica on wiry stems, which are characteristically bent and not stiffly erect as in the case of I. sibirica itself. The growth is much less compact than that of the European and Asiatic species, and the tufts of leaves appear at some distance from each other. To do well I. prismatica needs a moist, cool position.

All these irises are easily raised from seeds, and should be sown in the autumn in pots, which are best sunk to the rim in a bed of sand or ashes in an open position. The young seedlings should appear early in the year, and the pots may then be given the protection of a cold frame. By the end of May or early in June they should be big enough to be planted out in their permanent positions, where they should begin to flower in the following year.

AN EFFECTIVE GROUP OF IRIS DALMATICA AND LUPINS.

IRISES AND LUPINS

TO make a brave show in the herbaceous border during the first three weeks of June there is nothing more effective than a bold grouping of lupins and irises. The choice of variety is important, but even more so is the manner of planting, for the mistake so often made of planting nothing but the dwarfer plants in the forward positions must be avoided if beauty and not conformity is the first consideration, so many otherwise beautiful borders being spoiled by this, and having a flat and uniform appearance.

An occasional iris or lupin, for instance, among dwarfer plants when on the very margin of the border, or even growing so as to project over a flagged walk, breaks the outline and, standing apart, gives one the same sense of pleasure as the stray self-sown flower in path or wall.

In middle and backward positions tree lupins and polyphyllus can be grown intermingled, the differences in stature adding greatly to the charm of each, and the former making very bold growth where the soil is at all suitable. Neither plant is at all exacting in this respect, and lupins have become greater and greater favourites during the last few years, their delightful fragrance and the decorative effect of their habit of growth, as well as the development of a wonderful range of colours, having combined to increase their popularity.

Perhaps the most beautiful of the flag irises to grow with lupins is that shown in the illustration—Iris dalmatica—having several advantages for the purpose over other varieties and, being later in flowering than many of the group, it is at its best at the same time as the lupins. It is a most beautiful clear pale blue with slightly darker "falls," being much more striking than pallida or Florentina, two paler varieties somewhat resembling it. All three have glaucous foliage, but Iris dalmatica has a much bolder flag, and the flower-stem is proportionately much taller, many of those in the illustration measuring 3ft. 8ins. To add still further to its height and to make it free-flowering it is a good plan to plant the groups on small mounds in the border, for preference with a stone or rubble foundation and a couple of feet in diameter. This, while adding to the height, also ensures good drainage and has a very marked effect on the flowering.

CREEPING PLANTS IN THE GARDEN

BY DR. R. LLOYD PRAEGER.

FROM the point of view of a contributor, one advantage of an editor (of course, I mean one of *many* advantages) is that he sometimes suggests a subject for an article which the contributor himself would not have hit upon. A contingent disadvantage is that the contributor may not be quite sure what the editor is driving at. "Creeping Plants in the Garden" is capable of various interpretations, according to the taste and fancy of the interpreter. It might herald a procession headed by stonecrop or Solomon's seal or even Virginian creeper. When in doubt, it is well to begin with a definition; that clears the air and gives one a hint as to what one is talking (or writing) about. A creeping plant, according to Daydon Jackson's "Glossary of Botanic Terms," is one whose stem runs along or under the ground and roots at intervals. This excludes on the one hand plants which merely lie upon the ground (trailers) and, on the other, the so-called "creepers" of our walls and arbours. It includes all things that root as they run.

Creeping plants are plants with creeping stems, and to get at the inwardness of creeping stems, their variety and their vagaries, we must spend a few moments in considering the question of stems in general. The majority of stems, annual or perennial, show a more or less well marked alternation of nodes and internodes. The nodes are the points at which leaves are produced. They are often swollen; in hollow stems they are usually accompanied by a transverse partition; and they are the points at which branches and additional roots usually originate, or are capable of originating. The internodes are the spaces between the nodes. They are usually uniform throughout their length, and incapable of giving rise to branches or roots. The arrangement of the leaves on the stem, and also the distance between them (*i.e.*, the length of

Digitized by Google

the internodes) vary greatly in different plants, and it is this that to a great extent gives variety and character to their appearance.

While in plants with upright stems roots are seldom produced from the nodes (save when we plant portions of stem as cuttings), in creeping plants the production of nodal roots is characteristic. One effect of this is very important. A plant with upright stems has to rely upon its original root-system for all root purposes, that is, for the absorption of water and its dissolved salts, and for the safe anchoring of the plant; and no matter how much the stem elongates, these roots and the whole length of the stem are constantly in use, sending up materials to the growing parts. But in creeping plants the nodal roots short-circuit these arrangements. As the stem lengthens new roots are forming continually; the original roots and the older parts of the stem are not required, and die away, and there is no theoretical reason why a creeping stem should not go on creeping from Land's End to John o' Groat's, or why such a travelling plant should not continue creeping for a thousand years. When one looks at a field of bracken, one may reflect that the whole sea of greenery may have arisen from a single spore. Given only time enough, one scrap of couch-grass may fill a whole garden. This readiness to root at the nodes makes creeping plants very easy of propagation, since every node is a potential new plant. As we know to our cost, it makes weeds with creeping stems the most dangerous of all weeds, especially if these stems be underground, as in couch-grass, bracken and bindweed, for every buried scrap which is left behind in digging is capable of starting the trouble all over again.

CAMPANULA PUSILLA, ONE OF THE MOST CHARMING OF CREEPING PLANTS.

One or two other considerations relating to creeping stems have a practical application in gardening, and deserve mention. For instance, stems of this kind have not to maintain the weight of the plant as upright stems have, nor are they exposed to wind; therefore instead of becoming thick and stiff, they generally remain thin and soft. The roots, again, are somewhat ephemeral, since the plant keeps moving forward steadily; in consequence, though many, the roots are generally short. Perhaps it is for this reason that creeping stems are so characteristic of plants of wet places—the roots may not be long enough to penetrate to the damp lower layers of soil in places which are dry.

We may now proceed to review the various types of creeping plants as exemplified in our gardens, and consider how their peculiar modes of growth fit or unfit them for use in horticulture. To see creeping plants at their creepiest, we may take the "carpeters" of the rock garden—cotulas and acænas, the small New Zealand epilobiums, thymes, raoulias, Lippia nodiflora, etc. These have stems which lie close to but above the ground, producing small leaves singly or in pairs, and from the same points frequent tufts of fibrous roots. Two dainty tiny members of the same group are Arenaria balearica and Mentha Requienii. The usefulness of these carpeters in covering areas of soil or of path, or even damp stones, is well known, and needs no comment. In these plants there is only the one kind of stem, which creeps on indefinitely, bearing branches and flowers. Another common type is illustrated by the strawberry, sitfast, Geum reptans, several potentillas, etc. Here a short, erect stem produces slender prostrate shoots, consisting of a very long internode at the extremity of which a similar erect shoot and a tuft of roots are produced, also an extension of the prostrate shoot, which thus goes looping along till the close of the season, when the long internodes die away, leaving a number of rooted young plants sitting round the parent. A third type is exemplified by the common bramble, Lithospermum purpureo-cœruleum and the bugle, Ajuga reptans. In these the arching stems are leafy, and in autumn they take root at the tip to form new crowns in the following season. The crowns so formed may persist for many years, giving out similar shoots annually, as in the bramble; or they may flower and die in the ensuing season, as in the bugle. But the precise plan on which the plants work is very varied, and need not be followed here. Any gardener can study it for himself, and he will find it interesting and suggestive. The ultimate effect is that such plants tend to form a tangled mass of interlacing stems, spreading rather fast; their use and the dangers of their use in the garden are evident from this.

So far, the creeping plants which have been mentioned have stems which run *above* the ground, but many of the most characteristic of the creepers have underground stems. In some these stems prefer to be half-buried, and plough along with their backs showing above the soil. The great Saxifraga peltata does this conspicuously, and many irises. The blood-root (sanguinaria) and wood anemone show the same tendency. In all these the stems are very succulent, and are used to store up food. Their creeping, branching habit tends to the production of large patches. Many other familiar creepers prefer to keep their stems out of harm's way, 1in. or 2ins. down in the soil. Here belongs, indeed, the main mass of the creeping plants of the garden—woodruff and lily of the valley, Campanula pusilla and Calceolaria polyrrhiza, epimedium and maianthemum, helianthus and thermopsis—all kinds of plants, large and small, some spreading a foot per year and some an inch.

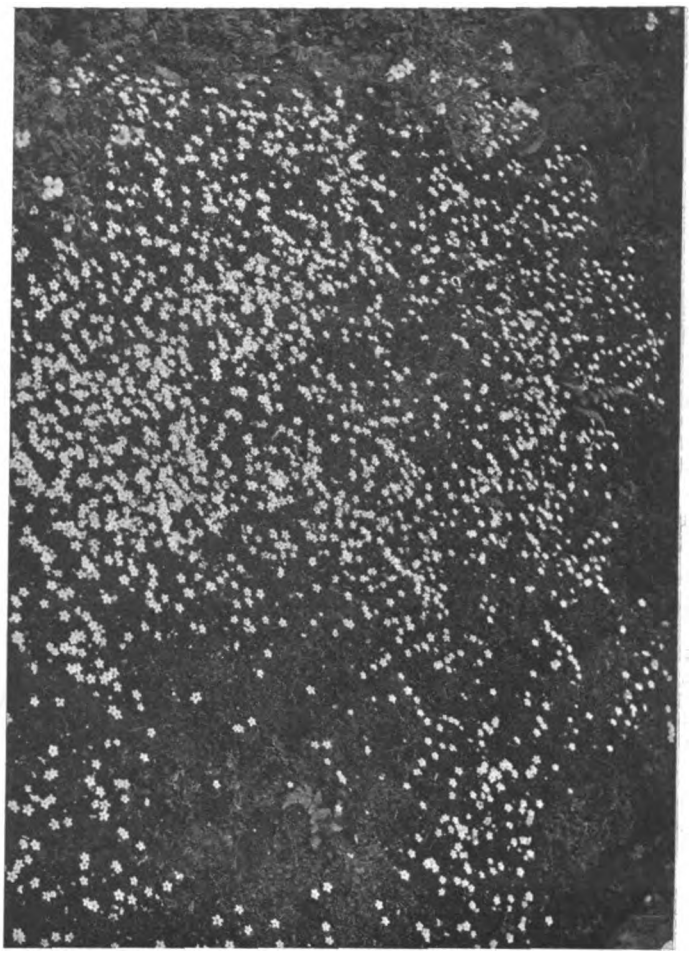
Where creeping stems are more deeply buried and cannot conveniently send each leaf up through the soil into the air, we often find a division of labour coming in. The main stem frequently has its leaves reduced to mere colourless scales, but along with similar underground branches it produces branches which grow up into the air and bear green leaves and flowers. This is what *appears* to happen in many grasses and sedges, but actually in these the subterranean stem soon grows up into the air, sending out a side shoot below which continues the underground stem, and in turn grows upwards. It comes to the same thing as regards result. In the creeping grasses and sedges the scale leaves, which are really ordinary leaves transmogrified, are often very hard and flinty, and at the

Digitized by Google

tip of the stem form so firm and sharp a point that one can prick one's finger on it. The usefulness of such a spear for forcing a way through hard ground can be imagined. In many plants the aerial and subterranean shoots, in pursuance of their respective functions, have become so unlike each other in appearance that if we saw them apart we could not guess that they belonged to the same plant. The bindweed and field thistle are familiar examples. In these the annual stems which bear leaves and flowers are highly developed and characteristic, while the perennial part consists of soft, colourless, formless, root-like growths, helpless-looking and ugly, but possessed of a fiendish vitality and power of penetration which places them in the forefront of enterprising and ineradicable weeds.

In some plants the scale leaves of the underground creeping stems are very conspicuous and peculiar. In the coralwort, for instance, of which one species, Dentaria bulbifera, is an English wild flower, the white, brittle underground stems are covered with tooth-like, white, fleshy scales, while the aerial portion consists of a smooth 2ft. stem bearing green, pinnate leaves and purple blossoms, and in the axils of the leaves curious shiny black bulbils, rough and scaly. These, if planted, grow at once into white scaly underground stems. The toothwort, another native plant, has stems still more scaly, and the scales are so curious in their structure that they were long believed to be insect traps, like the bladders of utricularia. From these scaly stems roots proceed which fasten upon the roots of trees and draw nourishment therefrom, for the plant is a parasite. The above-ground growth consists of cream-coloured leafless scaly spikes of succulent drooping flowers.

Creeping plants are not a race apart, but merge by degrees through the trailers into the main army of upright plants.



SOME CREEPING PLANTS, SUCH AS ARENARIA BALEARICA, ARE ESPECIALLY SUITED FOR CLOTHING SHADY WALLS.

THYMUS SERPYLLIFOLIUM IN A CHOICE SITUATION CASCADING OVER ROCKY STEPS

In species of very many different groups the stem has a tendency to develop roots when it is in contact with moist soil, just as roots often tend to produce shoots under the stimulus of light and air. These last are true *suckers*, which in the correct sense do not arise from underground stems, but from ordinary roots. Some trees produce them habitually, like the white poplar, and, in the garden, cherries and plums. The tendency of stems to root is much more widespread. Where it occurs in plants which do not creep we call it layering, and it is one of the most important means of increasing shrubs which do not strike easily as cuttings. Layering is, in a sense, forcing plants to creep which do not do so naturally.

The creeping habit is especially developed in plants of lakes, ponds and wet places, and it is this that makes the water garden so difficult a problem. Bulrushes (scirpus), reedmace (typha), sweet flag (acorus), arrowhead (sagittaria), pondweeds (potamogeton) and their fragrant cousin aponogeton, water lilies, all have stems which creep through the mud, many of them vigorously. Safely protected by the water, we cannot keep them in check, and in a few years hopeless confusion is the result. The marsh garden is just as bad, for marsh plants also generally creep. Look at the tangle in our own marshes of yellow loosestrife, water mint, gipsywort, skullcap, sedges and twenty others. How can we keep the water garden in order, then? Nohow, except by sticking to the comparatively few plants which do not creep, or only slowly. But by eliminating the vigorous ones, like typha, scirpus and that scourge the water horsetail, and re-making at intervals, order may be maintained to some extent.

Then there are creeping shrubs, some of which are as bad as the water plants for introducing confusion where one wishes order to reign. The well known snowberry, Symphoricarpus racemosus, is perhaps the worst offender in this respect. Some of the coriarias, too, need to be introduced with caution, as they run about underground and keep popping up where they are not wanted, and there are many others.

Digitized by Google

To sum up this rambling dissertation, a few facts emerge which are useful points for the gardener. Creeping plants in general have short roots, and need to creep in order to reach fresh food supplies. We cannot, therefore, confine them rigidly to a small area without periodical replanting and feeding. Generally speaking, they are suited to moist rather than to dry places. Those that creep below ground need constant watching if there are prized plants in their vicinity. Where they cannot conveniently be kept in check, as in water or among stones, they should not be introduced at all unless the intention is to let them run riot. A little fine top-dressing seldom comes amiss. In the case of rock plants it should be sandy, that it may easily work down through the tangle of leaves and stems.

DISEASES AND PESTS OF VEGETABLES.

GOOD cultivation does not consist solely of soil treatment, sowing, planting, feeding, training, etc.; it includes successful battles against disease and insect pests, which are always quick to attack weakly specimens and bring low the strongest, if they themselves are not killed or turned aside in time.

The following are some of the most dangerous diseases and pests of particular vegetables that the cultivator must guard against:

ASPARAGUS.

Probably many cultivators have observed bare places in their asparagus beds when the young "grass" is, or should be, growing freely. In many instances, the beetles and larvæ are feeding on the tender tips just under the soil, and examination should take place by removing soil. I have seen plants almost denuded of their young, feathery foliage in summer by the larvæ of the beetle. The soil should be freely covered with soot in the autumn, and in spring all beetles found on the bed should be killed; they are darker in colour than the ladybird. A soft-soap and paraffin mixture should be syringed on the foliage directly any larvæ are observed. Boil slowly 8 oz. of soft-soap for ten minutes in half a gallon of rain-water, and add 1 pint of paraffin afterwards. This will make 6 gallons of water for syringing forcibly on the foliage. The emulsion should be well stirred when being applied.

Asparagus rust is troublesome in some districts. If, in the summer, the plants turn brown, apply Bordeaux mixture in a fine spray, wetting all parts. The weather should be calm at the time of spraying.

BROAD BEANS.

Black aphides soon destroy the plants if they are not themselves destroyed directly they are found. They are dark brown, but are always referred to as black. When the plants approach the flowering stage, a constant watch should be the rule, and, on the appearance of the first aphis, remove the tip of the plant, as the pest starts at the top and multiplies downwards. The removed tops should be collected and burned. Little more trouble need be taken. The bean beetle is not often troublesome, as our seedsmen are careful in the preparation of the seeds. Furthermore, where seeds contain the beetle, the latter perish in them when the seeds swell in the soil. The same remarks apply to the seeds of peas.

RUNNER BEANS.

Thrips and red spider will, in some hot seasons, almost ruin the plants. The leaves of these plants are favourite homes of the red spider. The latter saps the strength-juices of the leaves, and, if left unchecked, reduces the latter to skeletons in a short time. Plants growing in a well trenched soil rarely suffer to the same extent as those in a poor, shallow one. The insects protect themselves by weaving webs, and light syringings leave them dry under the webs. The garden engine is better than the syringe,

but in each case the water should be directed to the undersides of the leaves. Use clear water only, and saturate the soil at the roots twice a week in dry weather, applying a good surface mulch after the first watering. Thrips often do much damage to runner beans, destroying the flowers as they open. The pests are sometimes conveyed to the new crop when old stakes are used again. But just before the flowers open syringe the plants with a soft-soap emulsion. Boil 1lb. of soft-soap in 1 gallon of rain-water and, afterwards, add 10 gallons of clear water. The soft-soap should boil gently for twenty minutes. The prepared liquid should be applied in a light spray, passing one way along the row and then return, treating both sides in a similar manner.

PEAS.

In dry weather, both thrips and mildew do a lot of harm to the foliage, and, should remedial measures be neglected, the crop of sound pods will be a small one. Vigorous syringing and judicious feeding with surface mulches will keep the growths clean and healthy. An attack of mildew may come where the plants are rooting in a constantly moist soil, or when they are, daily, artificially watered. Of course, we want the happy medium, and the conditions just referred to would result in a chill to plants and pods and conduce to a severe form of mildew.

Frequently, very fine pods are spoiled through the seeds in them being attacked by green and yellow grubs. When the flowers open, a moth lays her eggs in them, and, of course, they are enclosed in the pods, hatching as the seed swells to maturity. The only thing to do is to syringe the plants when the first flowers open, with a weak paraffin emulsion, or one made from quassia chips or extract, to render the foliage distasteful to the moth. The pea weevil eats the leaves, and sparrows are often blamed for this. Apply a light dusting of soot when the drills are open, and frequently after the young plants appear above the soil.

Mice sometimes destroy the seeds soon after they are sown. Procure some glass jam-jars about 7ins. deep, bury them at intervals of 7ft. apart, with the rims level with the soil. Three-parts fill them with clear water, and also smear some grease—mutton-fat for preference—inside the neck of each jar and just below the rims, approximately 1½ins. from the top of the jar; the mice, in trying to reach the fat, overbalance and fall into the water. As many as six are often so drowned in a single jar, and thus the quarter is cleared of mice in a short time. Rolling the seeds in red lead prior to sowing is a good old practice and often resorted to in these days.

As a guard against birds eating the pods and peas in them, nets are the best protection in the case of choice sorts required for special purposes.

POTATOES.

Perhaps, out of all the numerous drawbacks that the noble tuber is subject to, the potato disease (Phytophthora infestans) is the one most generally looked for and spoken of. In addition to the quality of the cultivation, we have such varying seasons as regards weather. Moist, dull weather, commonly called "close and trying," during the month of July, favours the spread of the disease. It would take up many pages to describe adequately, in detail, the whole life history

Digitized by Google

of this one disease and its remedy, so I shall only deal with the main points. It seems to me that the plants are more subject to this blight when they are grown on the same ground year after year and from home-saved seed. Change, in both cases, is highly beneficial, certainly, of seed, after the second year. New varieties are, generally, stronger and more disease-resisting. The Bordeaux mixture is the best known remedy, but it should be applied at the end of June, before there are signs of the disease, and twice in July. The tubers, as well as the leaves, become diseased. On a misty, dull morning in mid July, one may smell the disease as one passes by a field of potatoes. The spores are liberated by currents of air, and, being light, float away, settle on sound leaves and so infect them. The spraying should be done to make it difficult for the spores to live at all, much less multiply, thus acting as a preventive or preservative of the entire crop. Good and careful earthing-up does much to prevent the disease reaching the lower stems and tubers. If, however, the haulm is diseased, it should be cut off and burnt forthwith, as its functions are, naturally, impaired. Leaf-curl in potatoes is on the increase, but it is a disease that can be controlled very considerably. The writer has had much experience of it in the south. Seed tubers, ripened in a light, hot soil, will frequently remain hard in the soil when planted, instead of decaying, and the curled appearance of the foliage should suggest to the cultivator the condition of the "set." There is no cure, but it may be prevented if seed tubers are obtained from Scotland, or lifted at home before they are really matured, greened and sprouted in light, cool quarters. Potato scab spoils the appearance of the tubers. The writer has frequently observed badly scabbed tubers lifted on land heavily manured with fresh farmyard manure just prior to the planting; if a light sprinkling of lime is applied before the tubers are buried with soil, scab is not as bad even when fresh manure is used. In light soils, and in all soils thoroughly broken and manured with rotted dung several weeks before planting, scab is not serious.

Black scab first appears round the eyes of the tubers and then spreads all over them. It is such a bad disease that crops affected should be destroyed.

Wireworms are mostly troublesome in newly broken grassland. The grubs are generally found in the top 3ins., near the roots of the grass, and if this portion be peeled off and dried, then heaped and charred, the wireworm will perish. Vaporite is also very good, especially if mixed with the charred turves as they are dug in, as the fumes must be confined.

Leather-jacket grubs, the larvæ of the crane fly, can be destroyed by using Carter's "Kil-Jac." GEORGE GARNER.

MORE ABOUT THE SUMMER ROSE SHOW

AMATEURS' ROSES.

THE principal classes in this section contained many excellent blooms, and the competition generally was very good. The Amateur Champion Trophy was won by Dr. R. C. Turnbull, Colchester, who staged thirty-six particularly good exhibition roses. His chief sorts were Colchester, Lord Allenby, Red Star, Candeur Lyonnaise and E. F. Hudson. While the second prize collection of Mr. J. W. Hart, Potters Bar, was not quite so even in quality, it included excellent specimens of Captain Kilbee Stewart, J. W. Hart, Coronation, Gladys Harkness and Candeur Lyonnaise. Mr. F. Dennison, Leamington Spa, was a good third in this important class.

The sets of twenty-four blooms were of even higher quality than in the former class, and the first prize collection also won the Mawley Cup. This exhibit was staged by Mr. F. H. Fieldgate, Colchester, whose best blooms were of Hugh Dickson, Candeur Lyonnaise, A. Hartmann, Mrs. John Laing and Mrs. F. Dennison. Dr. Turnbull was a worthy second in this fine class, and he staged superb blooms of Mabel Morse, Mrs. K. D. McClure, Nellie Parker and Modesty. Mr. F. Dennison was a good third.

The exhibits of twelve distinct blooms also reached a high standard of excellence, and here Mr. C. H. Rigg, St. Albans, was first with J. B. Clarke, J. J. Glassford, Edgar Burnett, J. L. Mock and other good sorts. The second prize was won by Mr. A. Johnson, Bishop's Stortford, with a collection that, under other conditions, might well have taken first place. His very best were Coronation, Colleen, Modesty and J. L. Mock.

In the class for growers of fewer than 500 plants, the first prize collection of twelve blooms was also awarded the Mawley Medal as being the most meritorious exhibit in the whole of the amateurs' classes. Mr. K. de V. Pryor, Hitchin, included magnificent blooms of Mrs. C. Lamplough, Dr. A. Petyt (a brilliant crimson rose), Martha Drew and Candeur Lyonnaise. In his very good second prize set Mr. W. J. Bambridge, Kettering, showed Mrs. J. H. Welch and H. V. Machin of great merit. Mr. G. O. Nicholson, Market Harborough, had the best six blooms in this division.

Dr. Panckridge was the most successful exhibitor in the division for growers of fewer than 250 plants, and his six distinct varieties were all excellent. Mr. W. T. Cohen, Berkhamsted, was second. The extra class, open to all amateurs, also induced a strong competition, and the first prize was won by Mr. J. E. Raze, who included Candeur Lyonnaise, Bessie Brown and Mrs. C. Lamplough in superb condition. There was also an interesting and keen competition in the class for members who had not previously won a prize, and the chief honour was won by Mr. T. C. Hodgkins, Walsall, who included fine blooms of Lemon Pillar and Lady Plymouth.

The class for growers residing within ten miles of Charing Cross apparently suffered from the great drought. But Mr. A. W. Rogers, East Putney, who also won the first prizes for growers within eight miles and within five miles of the same centre, staged creditable blooms, which included Mrs. G. Norwood, Mrs. Elisha Hicks, Florence Forrester and Mme. Louise Crette.

There were some exceedingly good blooms shown in the first prize exhibits of amateurs who grow their blooms without any paid assistance. Mr. W. J. Bambridge had Coronation, Mrs. J. H. Welch and George Dickson. Mr. W. Sunderland, Driffield, had a lovely bloom of Mrs. F. Dennison. Dr. Panckridge had Candeur Lyonnaise, Dean Hole, Mrs. J. Marriott and Mrs. C. Lamplough of great beauty. Mr. G. W. Nicholson showed Modesty and J. L. Mock. Mr. A. L. Brine, Hythe, and Mr. J. T. Owen also showed blooms of more than average merit.

The tea roses were particularly good, and the first prize twelve distinct blooms shown by Mr. F. Slaughter, Steyning, included delightful specimens of Lady Plymouth, Mme. Jules Gravereaux and W. R. Smith. Mr. W. E. Moore, who had the best six tea blooms, included White Maman Cochet, the silver-gilt medal bloom.

Dr. M. Lacroze, Roehampton, has many times won the first prize for a group of roses and, as always, he had a very charming arrangement. His varieties included Betty Hulton, Mrs. Henry Morse and Mrs. H. Stevens. Mrs. Burgess had the best smaller group, and she used excellent blooms of Lady Inchiquin, Los Angeles and Sunstar.

Mr. H. R. Darlington, Potter's Bar, added to his many triumphs in the class for twelve roses of distinct varieties, showing General McArthur, Betty Uprichard, Florence Mitton and other good sorts. Mrs. Henry Balfour was second. Mrs. L. A. Tilley was the most successful with six varieties, having excellent stems of Silver Moon, Lady Hillingdon and Cupid. Una and American Pillar were well shown by Mr. F. Slaughter.

The baskets of roses were all very charming. The best two in the chief class of exhibition roses were excellent blooms of Mrs. G. Marriott and H. V. Machin, shown by Mr. J. E. Rayer, Worcester; and Dr. Turnbull was second with Mrs. G. Marriott and T. F. Crozier. Candeur Lyonnaise, shown by Mr. S. W. Burgess was first in Class 31, and mixed varieties shown by Mr. R. A. Smith, Hertford, was first in Class 34; while Dean Hole and Frau Karl Druschki won the first prize for Mr. E. T. Gann in Class 36. Avoca, shown by Mr. C. C. Williamson, was the best basket of twenty-four stems of a decorative rose. Mrs. Henry Morse, shown by Mr. W. T. Cohen, was the best twelve stems.

NURSERYMEN'S CLASSES.

The many baskets of cut roses in this section made a most delightful display. The best seven baskets were shown by Mr. H. Mattock, who included Mabel Morse, Louise Crette, Golden Emblem and Lady Inchiquin. Messrs. Chaplin Brothers in their second prize set included Mrs. Tresham Gilbey and Mabel Morse of great beauty. The best three were Margaret Dickson Hamill, Lord Charlemont and Mrs. Henry Morse, shown by Mr. G. Prince. Mr. H. Drew was second. Snow Queen, shown by Messrs. D. Prior and Sons, was the best hybrid perpetual variety, and Gloire de Chédane-Guinnoiseau, shown by Messrs. J. Crosfield and Son. The best basket of a hybrid tea variety was Mrs. H. Bowles, shown by Mr. G. Prince, and Messrs. Chaplin Brothers were second with the same variety. Mme. Jules Gravereaux was shown in the first prize basket of a tea variety by Mr. C. Gregory and also by Mr. Mattock, who was second. Mrs. C. Lamplough, shown by Messrs. Chaplin Brothers, was the best basket of any variety of hybrid perpetual, hybrid tea or tea rose put into commerce since January 1st, 1919, and Captain Kilbee Stewart, shown by Mr. G. Prince, was second.

ARTISTIC CLASSES.

Several well arranged and well grown roses were exhibited in the artistic classes. The dinner-table decorations excelled the exhibits

Digitized by Google

in all the other classes. Both the arrangement and conditions of the blooms in the bowls of mixed roses left much to be desired. Too much foliage had been used and the stalks of the blooms were not sufficiently long to form effective groups. The popularity of the variety Mme. Butterfly was noticeable. It was exhibited in nearly every class, and in many cases it was awarded a prize. Very beautiful specimens in perfect form were exhibited by Mrs. Courtney Page. The small rose foliage used with this rose gave a charming effect to the whole table. Mrs. F. Charlton gained a second prize in this class. Mrs. E. P. Butcher had some lovely blooms of Los Angeles, and Mrs. H. Barton made an attractive group with Emma Wright.

Mrs. Oakley Fisher was awarded the Nickerson Prize for a decoration of cut roses for a dinner-table. Ophelia was the variety used. Mrs. H. Barton was also competing for the Nickerson Prize, and received a second for the arrangement of Lady Inchiquin and a first prize for a bowl of mixed roses in another class. In a special class for competitors who had never won a first prize in the decorative section, Miss A. K. Lock received a first and Miss G. M. Zelley a second prize.

In vases of cut flowers, Mme. Butterfly was again the variety which received the first prize. Miss M. E. West was the exhibitor, and Mrs. Courtney Page won a second in the same class. The baskets of roses shown by Miss Griffith and Mrs. F. Charlton were both artistically arranged and in excellent condition.

In one of the table decoration classes, single varieties only could be used, and the beautiful blooms of Irish Fireflame were much admired. Mrs. Colston Hale won the first prize and Mrs. Oakley Fisher the second. In all the above classes amateurs only were allowed to exhibit. More vividly coloured varieties were, in many cases, used in the three open artistic classes. A table decoration of striking appearance was staged by Mrs. L. R. May, who used the variety Mrs. Henry Bowles to the very best advantage. Betty Uprichard and Roselandia could also be seen. Mrs. C. A. Tisdall had well shaped blooms of Mme. Butterfly in a prize exhibit; and Mrs. A. R. Bide also won a prize for the same variety arranged in a basket.

NEW AND NOTEWORTHY ROSES.

SALTAIRE.—Deep velvety crimson blooms, almost resembling burnt cardinal, characterise this hybrid tea variety. The foliage is rather excessive. The fragrance of this variety is exceedingly sweet. Shown by Messrs. Alex. Dickson, Limited.

APHRODITE.—The blooms of this hybrid tea are made up of rather pretty crinkled petals of a delicate pink. Buds are of a good shape. Shown by Messrs. Easlea.

MISS ANNA MARIE BALLEY.—A fine garden hybrid tea variety, orange yellow centre. Shown by Messrs. Easlea.

BEDFORD CRIMSON.—A fine scented crimson variety, very free and a vigorous grower. Shown by Messrs. Laxton Bros.

LITTLE JOE.—Good blooms of a fiery red colour, with petals cut at the edges. Shown by Messrs. D. Prior.

LUNA.—A hybrid tea variety with large blooms of perfect shape and of a pale yellow colour, which is deeper in the bud. Shown by Messrs. D. Prior.

LITTLE JULIET.—A good hybrid tea variety, carrying pinkish blooms slightly tinged with yellow. Shown by Messrs. D. Prior.

VIVID.—A fine exhibition variety, carrying well shaped flowers of a light crimson shade. The petals are of rich substance. Shown by Messrs. Frank Cant.

ELSE POULSEN.—A fine large single polyantha variety with beautifully frilled flowers of a delicate salmon pink shade. Shown by Messrs. D. Prior.

HERA.—A strong, bushy hybrid tea variety, with light crimson blossoms composed of rather prettily cut petals. Shown by Messrs. D. Prior.

CHARMING PRINCESS.—A good Pernetiana variety, the petals of the flowers having a yellowish base, which becomes pinkish on the outer margins. Shown by Messrs. D. Prior.

JOAN HOWARTH.—A fully double hybrid tea variety with flowers made up of large, substantial petals of a deep flesh pink colour. Shown by Messrs. Bees, Limited.

FIREFLY.—An excellent crimson hybrid tea sort, carrying sweet-scented, almost double blooms. The petals are of good substance and the foliage is also fine. Shown by Messrs. Bees, Limited.

CESTRIAN.—A fine hybrid tea exhibition variety with slightly fragrant rose-pink blooms made of close, overlapping petals of good substance. The foliage is handsome. Shown by Messrs. Bees, Limited.

NORA HENSLOW.—A good crimson single hybrid tea variety, with flowers made up of spreading petals and a good contrasting central cluster of stamens. Shown by Mr. F. Evans.

MURIEL CRONSHAW.—A sweetly scented hybrid tea variety carrying good white blooms with reflexed petals. Shown by Mr. F. Evans.

JOHN RUSSELL.—A fine hybrid tea exhibition variety of good habit. The petals are of good substance and of a deep crimson shade. Shown by Messrs. Dobbie and Co., Edinburgh.

MRS. TALBOT O'FARRELL.—A good pernetiana variety which will be found suited for all garden work. It is of a good upright habit and carries long, oval pointed blooms of a pink tinged with yellow colour. Shown by Messrs. S. McGredy and Son.

DORIS TRAYLER.—A hybrid tea variety of good habit and very free flowering. The colour of the blooms is a shade of yellow orange, while the outside of the petals is a crimson red. The foliage is good and appears mildew-proof. Shown by Messrs. McGredy and Son.

EVA EAKINS.—A fine pernetiana variety with blooms of a deep salmon pink contrasting well with the handsome well grown foliage. Shown by Messrs. McGredy and Son.

PATIENCE.—This hybrid tea variety is free and bushy, carrying well shaped blossoms with slightly reflexed petals of an almost crushed raspberry colour. Shown by Messrs. McGredy and Son.

WHITE ENSIGN.—We have already said that this rose is decidedly the best new variety of its type for some years. The perfectly shaped and dead white flowers of medium size are well carried on graceful upright stems, while the foliage is also to be admired. Shown by Messrs. McGredy and Son.

MRS. C. W. EDWARDS.—The flowers of this upright hybrid tea variety are of a light crimson shade with a yellow base, providing a vivid contrast to the dark green foliage. Shown by Messrs. McGredy and Son.

LADY LESLIE.—The fine well formed deep yellow flowers of this hybrid tea variety are rather inclined to break to pink. The flowers are carried well on stout, erect stems. Shown by Messrs. McGredy and Son.

MRS. S. PATON.—A vivid contrast is provided by this hybrid tea variety with its medium-sized flowers of a rose pink shade and its dark glossy green foliage. Shown by Messrs. McGredy and Son.

MARION CRAN.—The large well formed blooms of this hybrid tea variety are of a deep reddish-shaded pink composed of petals of rather a soft waxen texture. Shown by Messrs. McGredy and Son.

LADY WAKEFIELD.—This hybrid tea variety is a sport from Padre, and carries very delicate yellow blooms. The outer margins of the petals are tinged with rose pink. Shown by Messrs. B. R. Cant and Sons.

LADY HELEN MAGLOONA.—A vigorous hybrid tea variety carrying strawberry-coloured blooms which are neat and compact with close overlapping petals. The flowers are very fragrant. Shown by Messrs. Alex. Dickson, Limited.

LADY WORTHINGTON EVANS.—A very fine crimson red hybrid tea variety with the individual flowers of good shape and form. Shown by Messrs. Alex. Dickson, Limited.

FRANCIS SIMS.—A vigorous hybrid tea variety bearing numerous light, delicate rose pink blooms. The colour shades to a lighter tone towards the base of the petals. Shown by Messrs. Alex. Dickson, Limited.

DAME EDITH HELEN.—The large shapely blooms of this hybrid tea variety are of a fine shade of pink. These are carried on stiff, rather stout stems. Shown by Messrs. Alex. Dickson, Limited.

LADY MARGARET STEWART (hybrid tea) is characterised by its large, oval, egg-shaped blooms of a pure whitish yellow shading to a darker tone at the base of the petals, with a slight fragrance. Shown by Messrs. Alex. Dickson, Limited.

PRINCESS ELIZABETH OF GREECE.—Another hybrid tea variety, carrying medium-sized deep orange yellow blooms, which stand out well from the dark glossy green foliage. This variety looked well arranged in a basket. Shown by Messrs. Chaplin Bros.

MARS.—A sweetly scented hybrid tea variety, bearing medium-sized flowers of a shade of coppery pink, which becomes shaded with a bluey mauve, tinged with yellow at the base. Shown by Messrs. Chaplin Bros.

ELLEN TERRY.—A fine, sweet scented hybrid tea which has already gained a certificate of merit. The flowers are large and of a buff colour. Shown by Messrs. Chaplin Bros.

MRS. HERBERT NASH.—An excellent sweetly scented hybrid tea variety, with large, handsome blooms of deep crimson colour. Shown by Messrs. Chaplin Bros. Certificate of merit.

J. M. HART.—A hybrid tea variety, bearing large rose pink flowers, rather inclined to "blue." It is slightly fragrant. Shown by Messrs. Chaplin Bros.

LADY SIDNEY EARDLEY WILMOT.—A strong, freely branched decorative hybrid tea variety, carrying medium sized semi-double flowers of a deep salmon pink shade. Shown by Messrs. Chaplin Bros.

SENSATION.—A hybrid tea variety with large, sweet scented fine flowers of a rich dark velvety crimson. Shown by Messrs. G. Beckwith.

IVY MAY.—Hybrid tea. The rose pink blooms, flushed with gold on the outside of the petals, are most attractive. Shown by Messrs. G. Beckwith. Certificate of merit.

JOHN HENRY.—Another rich pink hybrid tea, carrying handsome flowers which are not too full. Shown by Messrs. G. Beckwith.

BLOSSOM.—The peach pink blossoms of this hybrid tea sort are flushed rose red, which shades to yellow at the base of the petals. There is a suggestion of tea fragrance. Shown by Messrs. G. Beckwith.

AUTOCRAT.—The large blooms of a pink to blush red shade of this hybrid tea variety are well formed and carried gracefully on long stems. Shown by Messrs. G. Beckwith.

ANGELE PERNET.—A vigorous Pernetiana variety, bearing vivid orange to copper blooms which are suffused with gold. Shown by Messrs. G. Beckwith.

ANNE.—A distinct and attractive hybrid tea sort with globular fragrant flowers of a cherry pink. Shown by Rev. J. H. Pemberton.

I. ZINGARI.—A fine semi-double sort with blooms of an almost coppery tint. Shown by Rev. J. H. Pemberton. Certificate of merit.

PENELOPE.—A hybrid musk, blossoms pink and well shaped. Shown by Rev. J. H. Pemberton. Gold medal.

THE PROVINCIAL ROSE SHOW AT BATH

THE combined show of the Bath Horticultural Society and the National Rose Society, which was held in the beautiful Victoria Park at the western city on July 9th and 10th, was a great success from every point of view. The entries were good and the exhibits reached a high standard of excellence.

With his usual generosity, the Mayor of Bath entertained a large party to luncheon, and pleasant speeches were made.

The President of the National Rose Society as the occasion demanded, was humorous and enlightening. Mr. Frank Cant made a delightful speech, and although Mr. H. R. Darlington spoke about roses and their fragrance, when he should have dilated on the unique beauties of the City of Bath, he was informative. But it remained for Mr. J. Pitt, who responded to the toast of the Judges, to coin the epigram of the day in "a raiser's pipe is full of sacrifices," and, as he said, we owe the delightful roses of to-day to the sacrifices made by raisers.

But, to paraphrase, "the show is the thing" and roses come first. The champion trophy was won by Mr. C. Gregory, who had thirty-six excellent blooms of Rev. F. Page Roberts, Mrs. E. J. Haddon, Earl Haig, Candeur Lyonnaise, George Dickson and similar varieties. Messrs. Frank Cant and Co., who were second, had charming blooms of British Queen, Florence Forrester, George Dickson, Candeur Lyonnaise and Lady Inchiquin. The best twenty-four blooms were set up by Mr. George Prince and these also were admirable, especially Lord Charlemont, Lady Inchiquin, White Maman Cochet and A. Hartman. Mr. C. Gregory was second.

The class for twelve blooms of roses distributed since January 1st, 1920, was particularly good, and Mr. Prince showed Souvenir de Claudius Pernet, Lord Charlemont, Mrs. C. Lamplough, Earl Haig, Muriel Dickson, Lady Inchiquin and Bessie Chaplin of great merit. Messrs. F. Cant and Co. in their second fine collection had Captain F. S. Harvey-Cant, Mrs. C. Lamplough and Mabel Morse of great excellence. There were many exhibitors of a basket of cut roses and Mr. C. Gregory was first with Mrs. C. Lamplough, and Messrs. A. Warner and Sons were second with Captain F. S. Harvey-Cant.

The five baskets of decorative roses were also of high quality. Messrs. S. McGredy and Sons showed Lord Charlemont, Mabel Morse and Gwyneth Jones of lovely appearance. Mr. J. Mattock had Lady Inchiquin and Louise Crette of considerable merit in his second prize set. Mr. Gregory showed The Queen Alexandra Rose, Golden Emblem and Mabel Morse and won the first prize for three baskets, and Mr. H. Drew, who was second, had a charming basket of Lady Inchiquin. Messrs. S. McGredy and Son, with a handsome basket of Mrs. Barraclough, was alone in the class for a basket of a new variety and deservedly received the first prize.

The extent and gorgeousness of the groups of cut roses astounded the general visitors, and, indeed, they were worthy of the highest admiration. Mr. E. J. Hicks had the best large group and had built up massed pillars of Climbing Ophelia, Los Angeles, Mme. Butterfly. Mr. George Prince, in his second prize handsome group, had arches of American Pillar, K. of K. and Red Letter Day.

In the medium-sized group Mr. C. Gregory was first, and he had many desirable sorts. The Rev. J. H. Pemberton was second. Mr. J. Mattock had the best smaller group. The best twenty-four varieties were staged by Messrs. A. Warner and Sons, which included Isobel, Hortulanus Budde, Betty Uprichard and Lady Roundhay in a fine exhibit. Messrs. F. Cant and Co. were second in this popular class, and Mr. E. J. Hicks had the best twelve varieties.

In the amateur section the Jubilee Trophy was won by Mr. J. W. Hart, Potters Bar, who had lovely blooms of Mrs. C. Lamplough, Gladys Harkness and Candeur Lyonnaise (the premier bloom of the section), among his twenty-four exhibition blooms. Mr. F. Dennison was a good second. Mrs. Hy. Balfour had the best twelve varieties, and Mr. A. B. Pim, was first with six varieties. Mrs. Hy. Balfour, showing White Maman Cochet, Mrs. Hubert Taylor, Maman Cochet and other fragrant varieties, was first with tea roses.

The artistic classes were very charming. Mrs. Courtenay Page had the best dinner table decoration and was also first with a lovely bowl of roses. While Mrs. Oakley Fisher has the best vase of roses. In the open class Mr. E. J. Hicks was first with a bowl of roses.

NEW ROSES.

The number of new seedling roses exceeded expectations and most of them possessed distinct merits.

ARTHUR COOK.—This splendid hybrid tea rose had previously won the certificate of merit and now received the highest award. It is a fully double bloom and very shapely in all stages of development. The broad petals are substantial and indicate a long period of usefulness. The colour is rich crimson flushed with velvety maroon. The neat foliage is crisp and firm and the stems possess few spines. Gold medal to Messrs. S. McGredy and Son.

DORIS TRAYLER.—A medium-sized hybrid tea variety, which is recommended for all purposes. The colour is old gold flushed with peach pink at the base of the petals. Certificate of merit to Messrs. S. McGredy and Son.

DUCHESS OF ATHOLL.—The colour of this hybrid tea rose is particularly fascinating and may be described as golden orange lightly flushed with peach. It is very beautiful in the bud and half open stages, but when fully open the charm of shape is lost, but the colour is fully retained. The stems are purplish, the neat foliage is very firm and the footstalks of the flowers are spineless. Certificate of merit to Messrs. Dobbie and Co.

DORIS TRAYLER, A FINE HYBRID TEA.

NANETTE.—This is a most delightful Wichuraiana variety. It bears plentiful clusters of fragrant, semi-double flowers which open roundly, disclosing a pretty cluster of golden stamens. The margins of the pure white petals are attractively undulated. It is recommended for pergolas and arches. Certificate of merit to Mr. Elisha J. Hicks.

THE BATH SOCIETY'S CLASSES.

Two large marquees were required to hold the exhibits in the classes arranged by the Bath Horticultural Society and these all were undoubtedly the finest that has been seen in Bath for many years.

In the open classes the groups of miscellaneous plants were very artistically arranged and the first prize arrangement of Mr. C. H. Smith was very delightful. The group of begonias which won the first prize for T. Crawford was excellent.

The first prize group of hardy flowers, arranged by Messrs. H. and W. Evans, was ideally beautiful, as was Mr. C. Wall's group of cut carnations; Messrs. Blackmore and Langdon's delphiniums were also admirable.

Sweet peas were of especially high quality and Sir Randolf Baker, Bt., Ranston, Dorset, was particularly successful in the open classes in which he showed magnificent spikes of such varieties as Wild Rose, Powerscourt, Fordhook Orange, Charming and Mrs. Arnold Hitchcock. In the amateurs' classes Mr. F. Churchward, Newton Abbot, was the chief prize winner, and he had lovely vases of Royal Sovereign, Pimpernel, La France and Wild Rose.

With roses Mr. E. Rayer was very successful, and he won the silver challenge cup and also had the best twelve blooms in the class open to those who do not employ a gardener.

THE SEMI-DOUBLE BLOSSOMS OF NANETTE.

SIMPLE GARDENING

DAHLIAS.

THE dahlia is a tender plant as regards frost; brittle and succulent of stem, and easily damaged by strong winds. Although tuberous-rooted, the plants soon show signs of distress when a dry spell of weather comes. If ordinary care be taken during the growing period, these plants do not cause the cultivator much real trouble; it is when we neglect them that damage is often done which cannot be repaired. The majority of lovers of large, brightly coloured flowers appreciate the dahlia, and those who are inexperienced only need a few hints in order to be successful with them. The plants require a deep, rich soil, and even those growing in such, now, will be all the better for a surface mulch. Plants in a poorer-rooting medium certainly need a rich surface dressing in addition to a mulch that will prevent undue evaporation. When engaged in attending to the plants, be sure that you avoid treading upon the soil near to the roots, as the plants do not thrive as well as when the soil is left in a natural open condition just above and around the tuberous roots. Spread on the surface around each plant half-rotted stable manure quite 3ins. deep. This dressing will be sufficient for all plants; failing it, scatter 2 oz. or 3 oz. of bone-meal on the border soil and cover it 2ins. deep with old potting or box soil or decayed rubbish from the garden heap and ashes from the smother fire, and apply one good soaking of weak manure water, now. Tie up the branches and add more stakes where needed.

TREATMENT OF SUMMER BEDDING OUT PLANTS.

Arranging and planting the bedding-out plants is always a busy and anxious time for the gardener. After this work is done some cultivators do not trouble themselves further about the plants, beyond giving applications of water in dry spells, such as we have recently experienced. But to obtain the very best from these border plants we must attend to them, if not daily, several times each week. It is not advisable to begin watering too soon, and when one does one should continue it consistently and apply plenty of it. There are two courses to take: one, thorough root soakings; the other, evening spraying of foliage plants, or the foliage of flowering plants, but not the blooms. The spraying refreshes, and prevents undue evaporation. Neat surface mulches are invaluable, as they, too, conserve moisture, prevent the sun unduly scorching the surface roots, and maintain the latter in a cool condition. Then there is the work of disbudding to attend to; the finest flowers on some stems are obtained by removing smaller side ones and, in the case of clusters, those around the central one. All fading flowers and leaves should be picked off daily if possible, or at least twice a week, if the beds are to be kept bright and fresh-looking. The removal of seed-pods and fading flower stems strengthens the remainder and the young ones to come. Staking is very essential and should be done neatly; while supporting the plants, the stakes should not be too prominent, and the ties ought to be just loose enough to allow the stems to grow.

STRAWBERRIES FOR FORCING.

Early runners taken from strong fruiting plants, firmly potted in good compost and nicely wintered in dry, cool quarters, will ensure success. I remember a lady showing me some plants in pots on her greenhouse shelf one spring, and how proud she was of them. But this pride was damped a little, owing to the lateness of the plants in flowering, and full disappointment came when I reluctantly told her that there would not be any flowers and, of course, no fruit. The real cause of the failure was the selection of quite unsuitable runners. The first young plant—the one nearest to the parent plant—on a runner should be layered, and all others beyond, on the same runner, should be cut off. These young layers may be selected from one year old plants that have borne fruits, or from two year old ones—also from those that have fruited. Often enough, one finds specimens that have not fruited surrounded by a lot of runners, very promising; and other plants, in the same row, possessing only two or three. The latter are the ones to select, and not those growing on the fruitless specimen; indeed, this latter plant, and all similar, should be dug out and destroyed. Layer direct into 3in. pots, using good fibrous loam, about six months old from cutting, and a small quantity of horse manure. Place a flat stone on the runner in the pot to steady the rooting plant and retain moisture round the crown and hasten the root growth. In due course, pot the young plants firmly in 6in. pots, this time adding a little bone-meal.

PLANTING OUT FORCED BULBS.

I know that many lovers of bulbs grown and flowered in pots, pans and boxes, discard them, as they think the bulbs are quite useless for the production of flowers in the future. If the bulbs are properly treated after the flowering stage is past, and, also, carefully planted out in an open border, a wealth of blossom will follow there year after year. The months of July and August are very suitable for planting such bulbs, and suitable positions are open borders or open quarters in new shrubberies. But for cutting purposes I much prefer the open border somewhere in the vegetable garden. To plant in orchards and similar positions where the ground is not kept quite free from coarse weeds is to court failure, as the full strength of each bulb, weakened by forcing, should be maintained and gradually increased, not lessened. Grade the bulbs and clean them without injuring their crowns; keep the kinds distinct and thoroughly dig and manure the border prior to planting, except in the cases where leaf-soil is abundant—then use the latter liberally and no manure.

THE DUTCH IRIS NURSERIES

DE GOEDE BROS.,
BEVERWYK, HOLLAND

Our specialty DUTCH IRIS
Highest award Chelsea Show, May 19th, 1925

PRICE LIST FOR THE ASKING.

NICOTINE INSECTICIDES

are by far the most efficient and economical for destroying all sucking Insects infesting vegetation

ENGLISH NICOTINE—95-98 per cent.
Full directions for using as fumigant or spray fluid.
Prices on application.

NICO SOAP (Nicotine Soap).
The best potash soft soap plus 7½ per cent. nicotine, for spraying or syringing work.
Prices: ½-lb., 2/-; 1-lb., 3/6; 10-lbs., 30/-

NICOTINE VAPORISING COMPOUND.
Nicotine content 50 per cent. In bottles for 2, 8, 16, 20, and 40 thousand cubic feet.
Prices: 1/6, 3/9, 7/6, 9/- and 17/6 respectively; ½-gallon tins, 61/-

CAMPBELL'S FUMIGATING ROLLS.
Very simple, for fumigating greenhouses. In four sizes for 500, 1,000, 2,000 and 3,000 cubic feet.
Prices: 7d., 10d., 1/6 and 2/- each.

CAMPBELL'S PATENT SULPHUR VAPORISER.
For vaporising sulphur. The best method of exterminating Mildew in glasshouses. Apparatus lasts for years. 5,000 cubic feet size, 18/-; 10,000 cubic feet size, 20/- each.

Obtainable through your usual Chemist or Seedsman or, in case of difficulty, write the Manufacturer,

J. D. CAMPBELL, Nicotine Manufacturer, 5, Lund St., Cornbrook, Manchester.

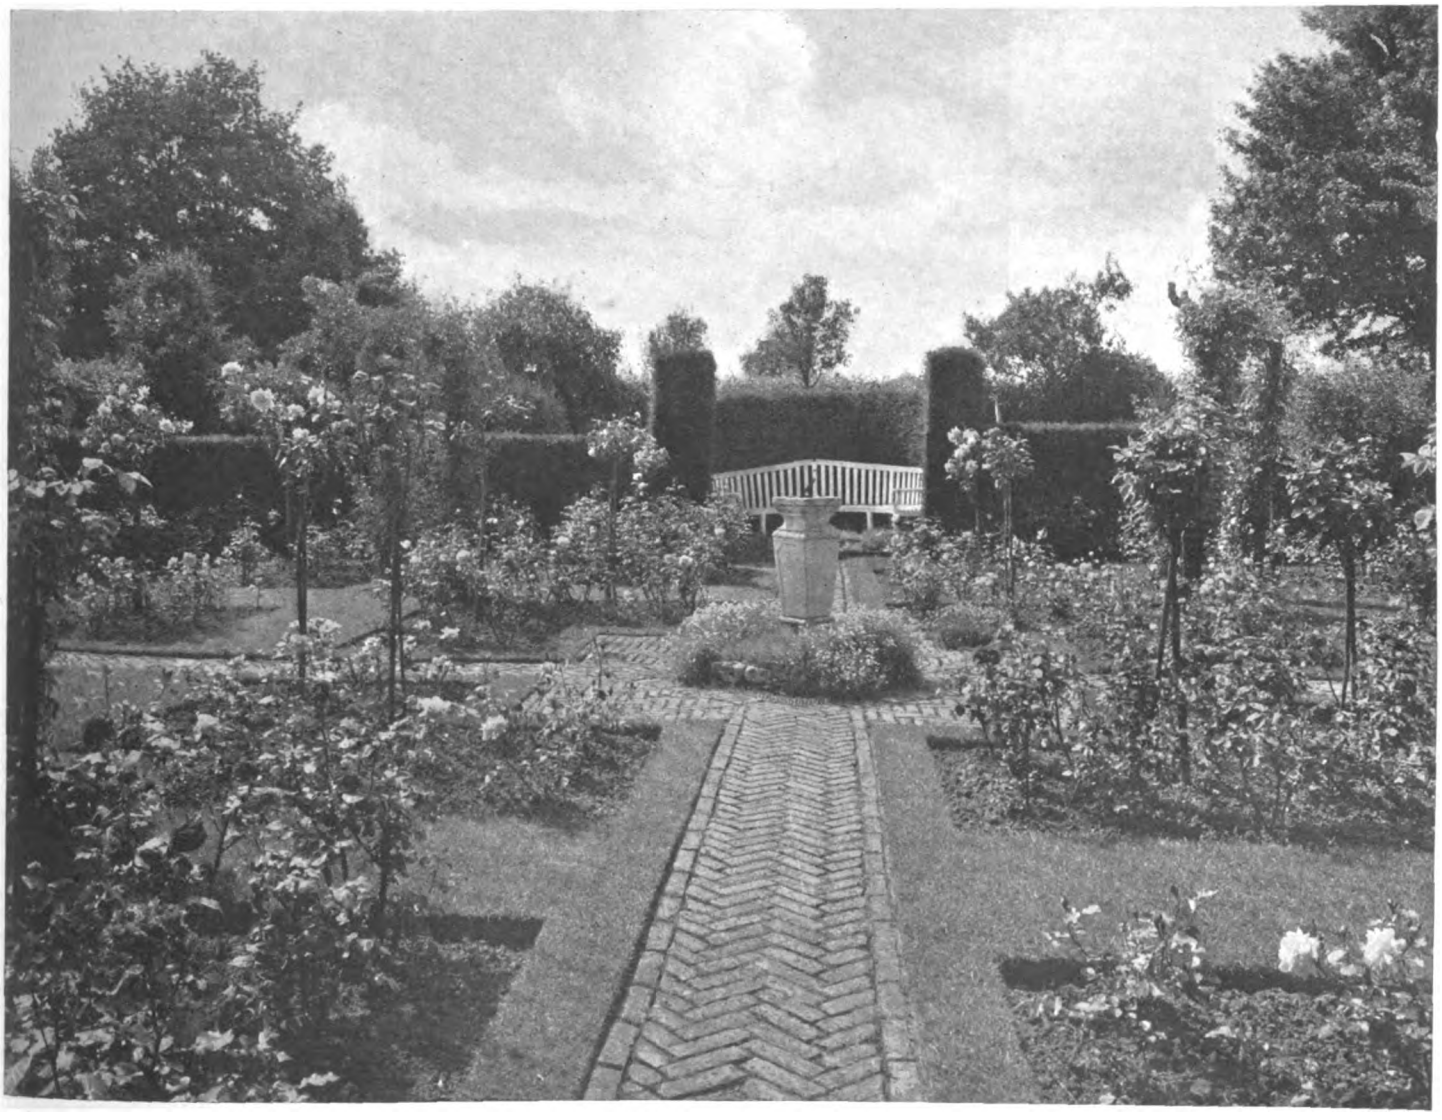
THE GARDEN

VOL. LXXXIX.—No. 2801. JULY 25, 1925

Price Threepence. Yearly Subscription, Inland, 17s. 4d.: Foreign, 17s. 4d. Registered at the General Post Office as a Newspaper and for Canadian Magazine Post.

Editorial Offices: 20, TAVISTOCK STREET, COVENT GARDEN, W.C.2. *Offices for Advertisements:* 8-11, SOUTHAMPTON STREET, STRAND, W.C.2.

Entered as Second-class Matter at the New York, N.Y., Post Office.



A SIMPLE YET EFFECTIVE DESIGN FOR A ROSE GARDEN. THE APPEARANCE OF THE BEDS IS GREATLY ENHANCED BY THE GRASS EDGINGS AND THE RED BRICK PATHS, WHILE THE EFFECT OBTAINED BY COMBINING VIGOROUS GROWING STANDARDS ALONG WITH DWARF VARIETIES IS MOST ATTRACTIVE.

PLANTS FOR THE PATHSIDE

THAT PART OF THE GARDEN FROM THE GATE TO THE FRONT DOOR IS PARTICULARLY SUBJECT TO CRITICISM, BUT IF A FEW OF THE UNDERMENTIONED PLANTS ARE INCLUDED THE RESULT SHOULD BE MOST GRATIFYING.

I OPEN the gate and any intelligent person would tell me that a few steps in space and a few seconds in time would find me at the front door. There is the path, perfectly straight, just a trodden brown earth path, there are no impedimenta, all is quite easy and simple.

But it isn't as simple as it looks, for the intelligent person was asked to look at the path and I see the flowers that are now growing in the beds at the sides, the flowers which have faded, but which I saw last time I passed this way, and more, those that will blossom before winter lays its hands on them all and sends them to rest.

There is the old apple tree leaning so gracefully and perilously because it is quite hollow, and over the hollow grows a Dorothy Richardson, kindly trying to cover the wound. The orange Dorothy buds smilingly lisp, "Don't notice the hollow," the older, cream-coloured roses say, "Please look at us and not at the sorrows of age." But their warnings are useless, for the gate made a noise as it opened and a tom-tit flies out of the hollow which is its home, or, at least, its summer residence. Silly bird, for Dorothy was doing her best to keep the secret of the tree's old age.

SEA PINKS BORDERING A NARROW PATH.

To the right is a Crimson Rambler, which had been budded on to a briar stock. The rambler never did very well, whereas the briar sent up branch after branch, until the gardener said, "Plucky, persistent little beast, its rough leaves are a jolly shape, anyhow. Let both the roses grow, let 'em fight it out." So there they are, together and so unlike. Under the earth they have a common dining-room, but up in the air their leaves take their aerial nurture independently.

The two plants react differently to moisture and sun and cold. The briar leaves come out first and drop first. When the leaves of the rambler are a little wilted on hot days, those of the briar still hold themselves proudly alert. When a frost comes the rambler succumbs, but the briar proudly displays a few very fat, red haws, while its leaves become bronzed or red or orange, before they pass away and leave the plant brown and bare. But if a few mild days come in November, or even in December, the rambler may unfold pale leaves and even experiment with a few green rose buds. Then the wise old briar, like a canny Brer Rabbit, "ain't sayin' nothin'." Inside its prickly brown stem it is amazed and rather scornful of the foolish adventurous ways of the upstart Crimson Rambler, which evidently has no well established tradition as to the correct behaviour of roses in November and December. This young thing, with so recent a family history, evidently has a mind which is easily led astray by December masquerading as May.

The blood red, small, dainty, tidy blossoms of the rambler, and the large, irregular, fade-red of the briar, do not go well together. This hybrid plant is not really proper to have in the garden, but there they are, two children whom life has produced. They shall do as they like, or as they can. Year by year the gardener will watch, and perhaps some day he'll know which is the winner.

At my feet is a great tussock of sea thrift (armeria), a plant that is beautiful every day of the year. I am not sure whether I like it better when it crouches by the path like a round, green hedgehog, or when, for a few weeks, it is like a great green cushion stuck with lovely pink-headed pins; then it is full of memories: Cornwall, a high cliff, a blue sky, a bluer sea and pinkness everywhere, not only in easy places, but there are little bunches of pink on tiny dangerous ledges, masses of pink on pieces of cliff that are just going to fall down into the sea, pinkness growing among pebbles on an inhospitable old raised sea beach. This thrift had a great adventure. A community of ants made a home near its roots and threw up a mountain of earth and ant eggs into the middle of the plant. It was cleared away several times, but the ants were so persistent, that finally the ant mountain was allowed to protrude from the middle of the green tuft. That little area of earth was not long allowed to remain a desert in a country so full of seeds; first a lesser crane-bill grew into a pretty rosette, but it did not produce a flower, then a columbine made a start, but it did not get beyond three of its tiny frilled leaves, finally a spiked valerian usurped the minute desert, and now has one little blue spike proudly sitting in the midst of the pink-headed pins.

Next door, clinging closely to the ground, is a plant of dwarf mountain thyme. It covers the earth in a thick, tight way that paint covers wood. Just before it comes into blossom it has a very cosy appearance, for the buds are protected by a fine down which makes the little patch look like a miniature purplish-green blanket. Soon the flowers will be out. Then I shall stay a long time by the little plant, to see the rich reddish purple of the tiny petals and I'll lean over to break off a minute leaf that the air may be luscious with summer fragrance.

The patch of lungwort (pulmonaria) leaves is getting rather shabby. I am sorry when their time for rest comes, because I am so grateful to that little plant for producing its simple protean flowers so early in the year. Most flowers come when flowering seems so easy and so simple, for they come into a warm and sunny world, but the lungwort pushes its delicate, blue-red, red-blue flowers out of a hard earth and into an air which may get nasty tempered at any moment.

There is a fascination in these flowers, which are pink or blue and which change from one colour to another, like a chameleon in the tropics. Even their full calyx is good to look at when the flowers have fallen. I have a special copper cup in which these flowers find a place year after year. Lungwort is not one of the gorgeous flowers, but it is well worth growing for its quaint, spotted leaves and its early bravery and delicacy. I would like to know how people prepared it for the curing of lungs in the old days. I wonder if it ever did any good. But it is certain that the mother was glad to do something that might be useful to the suffering husband or child,

Digitized by Google

and the sufferer was grateful to have any treatment to break the ennui of the long hours of waiting for the return of peace and health.

All the plants which have been used as medicine have a special human appeal; suffering is and has always been so near, so inevitable, that we cannot but look upon these helpful plants as friends and comforters. Lungwort was supposed to be good for the lungs, because its leaves have the spotted appearance of diseased lungs, just as greater celandine was good for biliousness, because its juice was yellow. I wonder if, on the same principle, they cured drunkards by letting them consort with other drunkards and turned bad-tempered folk into sweet-tempered by housing the villains together.

WHITE CANTERBURY BELLS, NEITHER ARISTOCRATIC NOR PLEBEIAN.

Somewhere in the background is a leopard's bane (doronicum), a lovely, gay plant, each blossom a foretaste of summer, each flower an August sun in April. It has, like all plants, its own proper and orderly time of flowering, but also an erratic, disorderly habit of producing a flower or two in August and one or two even in December. One wintry day you go out to see the garden, now like an old lady wrapped up in grey and brown, and you find one patch, perhaps two patches, of colour. One noon the wintry sun winked at the doronicum and as a result the plant suddenly produced two flowers, not gold, but making an effort towards goldiness. Gather them quickly, lest a frost curl up the petals and brown their tips, put them in a little green glass vase and stand them on the mantelpiece above the bright December fire. The fog may be thick, rheumatism may give you twinges, your nose may be red from a cold, but the little flowers sing a spring song which only the very stupid cannot hear. Even the flames of the fire hear and are apologetic, knowing what a poor substitute they are for the warmth and light of a May sun.

The lupins have been cut down, but their palmate leaves are busy, wide open by day, partly shut by night, but always breathing, breathing, storing up food for that time when each plant will send up its light, hollow stems to produce, one, two, three church spires, graceful like the spires of Coventry, Salisbury, but not quite as light and wonderful as the lace like spire of Ulm. The lupin paints her spires blue or blue and white, but man does not dare to paint the spires that he has made. Sometimes, however, the sun, when it draws near its setting and becomes friendly to man, so friendly, indeed, that man may look him full in the face, will pains the human spiret gold or yellow.

And here's another blue, anchusa, queer, straggly plants, hardly ever really erect, bearing in a thoroughly untidy manner its impudent and glorious blue flowers, those flowers with a cold, snow-white heart which stare at you, demanding allegiance, even obeisance, but which never become familiar, loving. How different from the hare bell, which seems just about to die of love and love for you alone.

The Canterbury bell on the other side of the path is somewhat betwixt and between the independent anchusa and the amorous harebell; it is a cosy, welcoming, homelike flower, willing to let all share in the blueness of its deep cup. Its five petals smile up at you as they turn back from the edge and show the yellow treasure. The humble bee is welcomed into the blue velvet boudoir, but, restless creature, he never stays long and yet he looks so sluggish and lazy. It is just possible that in his search for gold, he did not look round the blue room; probably thieves do not usually take an interest in the artistic furnishings of the houses they rifle.

The pink Canterbury bell is a delicate, sweet lady, but looks rather frail beside her blue cousin; the humble bee seems like a little bear when he visits her, much too rough in his manners for such an aristocratic lady, for she is Marquise La Rose, having risen socially above her family, who for generations have been merely Mr. and Mrs. Blue. The white Canterbury bell is neither aristocratic nor plebeian, but a strange and not very satisfactory exotic, whose complexion easily turns into an unpleasant brown when hit by a rough or cold wind.

As I leant down to look at a black and yellow ladybird on a grass plant, I heard a voice: "So you have come. We thought we heard the gate shut, but that was a long time ago."

O. A. MERRITT HAWKES.

THE DAISY BUSHES

BY SIR HERBERT MAXWELL.

The olearias or tree daisies of New Zealand consist of about forty species, with, in addition, a number of fine hybrids, the majority of which remain unsurpassed for their beauty of habit and profusion of blossom. As Dr. Cockayne, the eminent botanist, has said in one of his books, "their value for garden decoration equals that of the veronica." They fall naturally into two or three groups, which include species suitable for planting in gardens near the sea where moisture is plentiful, or in rocky and rather dry areas, or again, at the other extreme, in swampy positions. A wide range is thus offered in their cultivation, and with their handsome and striking appearance and charming flowers, they are deserving of being more widely cultivated in our gardens.

ALTHOUGH most of the shrubs from New Zealand, especially those from the North Island, will not endure the rigour of winter in midland Britain, yet there are wide tracts of our country—practically all parts near the sea—where many of them flourish as freely as in their native land. Among these are the daisy bushes—olearia—than which there is no class of evergreen that flowers more profusely, none better fitted to relieve the monotony which too commonly prevails in private shrubberies and public watering-places, none less exacting in cultural requirements where the climate is mild enough to suit them. The hardiest of the genus is O. Haastii, which endures even the trying extremes of heat and cold of London, and is pretty generally known and grown. It shrouds itself with a cloud of white blossom in August and

Digitized by Google

may be grown as a useful hedge plant near the sea; but, like all the other species, must be protected against rabbits.

O. chathamica and O. semidentata, both from the Chatham Islands, are reckoned among the tenderer species, yet the former grows well in the open in the Edinburgh Botanic Gardens, which are not blessed with a languorous climate. As for O. semidentata I cannot speak with any certainty, for I think that the plants we have grown under that name at Monreith are a narrow-leaved variety of O. chathamica. Both are very desirable shrubs, with thick, leathery, ever-green leaves and large solitary flowers, those of the latter having white or pale mauve ligulate rays round a dark violet centre, while the ray florets of O. semidentata are described as purple.

One of the tallest and most ornamental species is O. macrodonta sometimes erroneously called O. dentata, which is a tender Australian species. It may grow 20ft. high and makes a beautiful appearance when loaded with broad corymbs of small white flowers. It is sometimes confused with O. ilicifolia (holly-leaved), but its foliage is much broader and more like a holly than that of O. ilicifolia, whereof the leaves are linear-oblong or lanceolate. The two species are equally ornamental, growing to the same height and diffusing a similar musky fragrance when bruised. I used to wonder why, notwithstanding the vast quantity of feathered seeds that float away from these and other species of olearia, it was so seldom that one came across a self-sown seedling, nor was it until quite lately that the reason was found. A piece of ground having been cleared for the erection of a tool shed, many scores of seedling O. macrodonta colonised it, as no doubt they would do any bare ground not under tillage.

O. nitida is a very handsome evergreen, bearing plenty of large, rounded corymbs of white flowers in May and June.

OLEARIA HAASTII, THE HARDIEST OF THE DAISY BUSHES,

ONE OF THE MOST ORNAMENTAL SPECIES, OLEARIA ILICIFOLIA WHICH THRIVES IN A SHELTERED POSITION.

The leaves vary from 1½ins. to 3½ins. in length, bright green and shining above, white and satiny beneath. Inferior in beauty to this species is O. avicenniæfolia, but valuable in that it defers flowering till August. O. Colensoi is well worth growing for its fine foliage, the leaves being 6ins. long, very thick and leathery, shining green above and white below. The flowers are rayless, brownish purple, and are borne in racemes. Cheeseman reports this fine species as growing 30ft. high. O. Traversii, from the Chatham Islands, grows equally tall, with leaves 1½ins. to 2½ins. long, but it is a disappointing shrub, bearing flower panicles in profusion, but the flowers are rayless, greenish-greyish-yellow and inconspicuous, altogether not desirable for ornament.

Very different in appearance from these large-leaved species is O. nummularifolia, a stout, densely branched shrub which, so far, stands 6ft. high at Monreith and as much in width. Its white-rayed flowers are not borne in the same lavish profusion as those of several other species, but its foliage entitles it to a good place, being of a rich olive green. The rounded leathery leaves, never more than ½in. long, are closely set along the branchlets with revolute margins.

O. stellulata or Gunniana, from Tasmania, are so nearly alike that I cannot pretend to distinguish between them. They (or it) cannot be accounted as hardy as the species mentioned above, but they flourish freely in maritime districts, being covered with pure white blossoms in May and continuing much longer in bloom than any other species known to me. In stature they do not seem to exceed 4ft. or 5ft. O. insignis is reported as high as 6ft. in New Zealand, but I have not seen any specimen more than half that height in this country. It differs remarkably in appearance from any other daisy bush, having earned its specific name insignis—"distinguished"—by reason of its great leaves and large white flowers, 2ins. to 3ins. across. Being native to the South Island of New Zealand it is probably hardier than it gets credit for; at all events, I have seen it growing happily far from the sea in Sussex.

Different again from all other forms of olearia is the group represented by O. virgata, of which the small, narrow leaves are set along the slender branchlets in opposite fascicles, giving the shrub a plume-like appearance. This completes the list of daisy bushes whereof I have personal experience; but there are others among the five and thirty species of olearia indigenous to New Zealand which seem to be worth planting. Among these is O. lacunosa, with narrow leaves 6ins. and 7ins. long, about which Mr. Cheeseman observes that "its singular foliage should induce horticulturists to make the attempt to grow it!"

O. Lyallii, from the Auckland Islands, reaching a height of 30ft., with leaves 8ins. long; OO. Traillii, angustifolia and fragrantissima, from the South Island, seem to be desirable subjects.

HARDY ORCHIDS IN HERTFORDSHIRE

ORCHIDS of various types are plentiful in this country and they, of course, are of much interest to all lovers of our native wild plants when met with. There are no fewer than a dozen varieties that I have discovered myself in a radius of ten miles. They are found in the woods, pastures, chalk hills and moist meadows, according to the type and their requirements. I have noticed that practically in every case one species is never alone, but usually one or two other species are close at hand—in one instance about nine species are growing in a quarter of a mile radius; this I consider is an exceptional piece of rich flora.

We find Orchis Morio in abundance in the moist turf, in all its varying handsome shades; from the deepest purple to the palest blush pink, with very many intermediate shades, of which the delicate salmon pinks are favourites. Pure white forms and creamy also occur, but these are rare with us. The common name "Green Winged Orchis," describes beautifully the feature of the flowers, whose two side petals or wings have lines through them of a bright green colour. The flowers are carried on spikes a few inches high, from a tuft of sturdy dark green leaves.

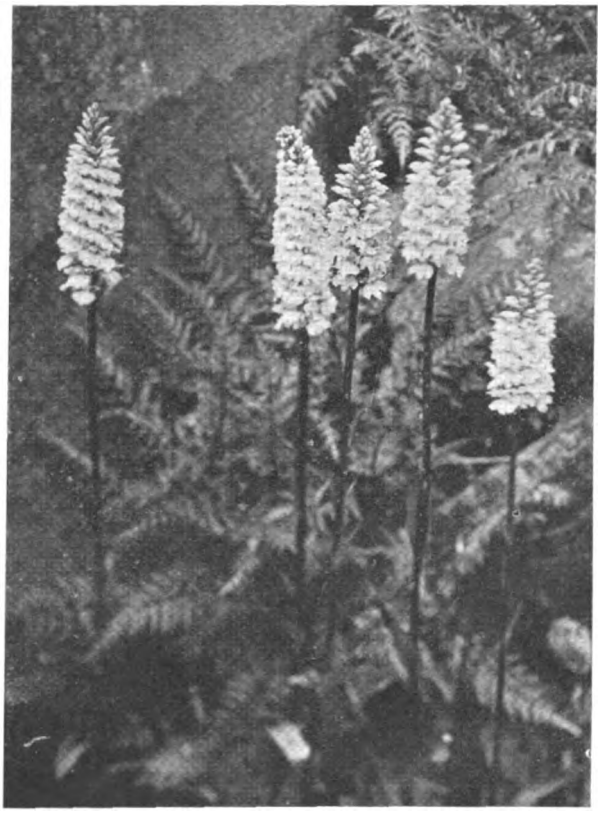
Orchis mascula, known as the Early Purple, abounds in great numbers; usually in moist, shady places. The woods appear to produce by far the best specimens, where the flower spikes attain a height of a foot or so, carrying the deep purple blossoms, and the leaves are long and fat, showing the results of a comfortable home. The leaves are conspicuous by the myriads of dark brown spots that share the upper surface, in odd cases the leaves are spotless. The colour of the flowers does not vary very much, and it is in very rare instances that an albino is observed.

In similar positions we find the Twayblade, Listera ovata, with its broad, oval, heavily veined leaves, that are situated two or three inches from the ground on its round stem. Only two leaves are produced on one stem and they are directly opposite. From the middle it throws up its 6in. to 9in. flower spike, carrying many curious green flowers which are certainly more quaint than pretty. It does not form tubers, as do the two preceding items, but forms dense mats of fleshy roots.

Habenaria viridis, the Frog Orchis, is again not very handsome to look upon, having small green flowers on 6in. stems, but this is not very common. Its leaves are long, narrow and bluntly pointed, and palmate tubers are formed.

Habenaria bifolia, the Butterfly Orchis, is fairly common in the woods, where it produces a pair of opposite, glossy, pale green lily-of-the-valley-like leaves. Several large flowers are carried on a 12in. stem in May and June. They are a creamy colour, the petals being arranged to present a starry appearance, and possess an extremely long spur in the rear, but the likeness to the butterfly is rather distant. The flowers give off a delicate sweet perfume, which is most pronounced at the close of a warm day. The tuber it makes is long and runs out to a point.

Spiranthes autumnalis, the Autumn Lady's Tresses, seems rather uncommon. It is quaint, yet handsome in its way, with numerous tiny white flowers arranged in a single row that winds round and round the 3in. slender stem in a spiral manner; they are also fragrant. After flowering it forms a rosette of short, sturdy glossy green leaves which sit perfectly flat and do not exceed an inch in height; these remain so, until shortly before the next flowering period, when they wither away. Two or three ovate tubers are formed underground in a cluster. It is autumn flowering.



THE WHITE FORM OF THE SPOTTED ORCHID.

Ophrys apifera, the Bee Orchis, has numerous stations in Hertfordshire, and is usually to be found in a chalky neighbourhood, where it occupies sunny aspects and dry positions. It is quite one of the favourites and certainly very popular, with its handsome flowers, made up of three rosy-lilac petals and a lower lip of a dark brown colour water-marked, as it were, a lighter brown shade. The edges of the lip are rolled backwards slightly and at once give the appearance of a velvety bag or pouch, strongly resembling the body of a bee, hence its name. The flowers are borne on spikes 6ins. to 12ins. high in June and July. It forms oval tubers and has bright green leaves up to 6ins. in length by about ¾in. in width.

Orchis ustulata, the Burnt Orchis, is in flower at the same time, and also occurs in chalky districts, but is not so common by far. It is a neat and curious little orchid, very dwarf in habit (3ins. or so), with between ten and twenty small flowers thickly placed on short spikes. These are of a deep purple colour and a lip of white, spotted with purple, contrast greatly and break the monotony of a dull shade. Small oval tubers are also produced in this instance.

Gymnadenia conopsea, the Sweet Scented Orchis, is a species the scent of which is one of the chief features, being extremely sweet and fragrant. It inhabits the dry, hilly pastures in the vicinity of chalk, and its rosy flowers on dense slender spikes poise gracefully above the short grass. The flowers appear in June and many constitute a spike. The foliage is long and narrow and the tubers it makes are palmate with four or five points or fingers. Creamy white forms are rarely found and they are quite good.

Epipactis grandiflora (the White Heleborine) rarely frequents our woods where chalk is in evidence. Its dull green lanceolate leaves clasp its 18in. stems at short intervals and from the axils its sessile, creamy-white flowers, yellow lipped, are produced during the months of June and July. For some reason or other the flowers fail to expand themselves as much as would be anticipated, and therefore do not show off to the best advantage. The plant does not form tubers but, instead, makes a dense bundle of tough, wiry roots, and lies perfectly dormant in winter, whereas most of the preceding items are in leaf at that time.

Orchis pyramidalis is a handsome species having extremely fine and beautiful flowers, usually of a clear rosy pink. Variation does not seem very general, and only on odd occasions have I witnessed pure white forms. The flowers are densely arranged in a pyramid-shaped head which tops a 6in. stem. Leaves are deep green, long and narrow, and make a tuft hardly rising above the short grass in which they are found. Sunny positions on poor chalky ground appear to be their ideal habitat. Flowers June and July.

Orchis maculata, the Spotted Orchis, is one of the commonest, abounding in great numbers in the moist pastures and meadows, and sometimes in woods. The usual colour is a pinky white, but there are specimens that are pale pink, also dead white. In all cases the flowers are markedly spotted and are produced in compact heads about a third of the length of the stalk.

F. BARKER.

BLUE IN THE GARDEN

WHO does not love blue? The colour chosen by the Roman Catholic church for the robes of the Madonna and typified by the expression "vouée au bleu," given to little maids in France to signify their devotion to the central figure of their religion. When Maeterlinck sent the children Tyltyl and Mytyl in his fairy play in search of the wonderful lucky bird, did he not choose blue for its plumage? So in the garden blue is the colour most prized by gardeners; partly for the sake of the colour itself and partly on account of the supposed scarcity of blue flowers. During the early months of last year *The Times* had an article from the pen of their garden correspondent on this subject, and though he seemed to me to be unnecessarily strict in his definition of blue, as applied to flowers, his remarks about catalogue descriptions of blue flowers were very much to the point. The blue rose, for instance, with its dingy mauve flowers and the well known Gladiolus Baron Hulot, could not be considered blue by the wildest stretch of imagination.

We must try to arrive at some sort of definition of blue in this connection. Science simply divides up white light into three primary colours, red, yellow and blue. But the extreme blue end of the spectrum is often referred to as violet and the expression "ultra violet rays" has quite a definite meaning. If we, therefore, admit all flowers which are blue according to the scientific definition of this colour and exclude all those which have much red in their composition, we shall find that we still have quite a long list.

When I speak of *blue in the garden* I do not mean that we are to have none but blue flowers, but rather that the dominating note might be blue, bearing in mind Whistler's stinging retort to the critic of his symphony in white: "Bon Dieu, did this wise person expect white hair and chalked faces? And does he then, in his astounding consequence, believe that a symphony in F contains no other note, but shall be a continued repetition of F, F, F? . . . Fool!!"

Blue in the garden can easily be overdone, as a correspondent, writing from Norfolk in reply to the article mentioned above, was only too ready to admit, as "the resultant effect was too cold, at all events for an English summer." If properly managed, however, there is nothing lovelier than blue in the garden. From early spring to latest autumn we can have bold patches of blue set among the green of leaves, like a sapphire in a ring. Only a few weeks ago I came across such a patch in Nature's own garden, composed of numberless spikes of bugle (Ajuga reptans), a plant which is well worthy of a corner in the rock garden, especially in the variety with variegated leaves, which show off the blue flowers to the best advantage.

Who cannot call to mind a beechwood in early spring, with the sunlight glinting through the boughs, with their tender young green, on to patches of bluebells growing thickly beneath?

The first blue effects of the year are, in fact, obtained by the judicious use of small bulbous plants, such as the grape hyacinth, scillas, chionodoxas and puschkinias. Perhaps, too, we may add the crocus, though the flowers are a bit purplish. Then come the hyacinths, which I like to grow in tubs close to the house so that their scent may enter the open windows.

Very early the blue anemones come into flower. First of all one from the hills of Greece, closely followed by its neighbour from the Apennines, with its astounding roots like bits of knotted charcoal. Then there are the little hepaticas, so common in the woods of Switzerland. The blue of the St. Brigid and the poppy anemones cannot compete with these little wild species and are best grown mixed together with the gay red shades in a border by themselves.

Early in the year, too, come the blue primroses, raised from seed each alternate year, for the colour is not fixed. If this is not done they revert to purplish shades. A packet of mixed seed from one of the large seed firms will yield a goodly assortment of shades from pale to deep violet blue. They often come like polyanthus, several on a stem. The true blue primrose was, however, discovered by Winter and named after him. He tells us how he found it in the Himalayas "growing at the edge of the snow, a patch of blue, looking lovely with the rising sun shining on it between the trunks of the trees, in delightful contrast with the white of the snow and its whitened leaves. It was a primrose with twenty or thirty blooms; at that elevation (10,000ft.), and with that clear atmosphere, really blue without that mauvish tint which it has chosen to assume in duller England."

THE INTENSELY BLUE ANCHUSA IN A CHARMING SETTING.

It is to annuals or, at any rate, to small plants raised from seed that some of the best blue effects in the garden are due. Many of them when once established can be relied upon to look after themselves year by year. Thus a blue haze composed of myriads of the small blue flowers of the forget-me-not creeps over the garden. It is the forget-me-not family which provides us with by far the greatest number of really intensely blue flowers.

As the forget-me-nots grow pale and finally fade away the blue violas come into bloom, edging all the paths and running along the side of the lawn. Some of them are, perhaps, not quite blue within the definition, but the impression produced is certainly one of blueness. If the dead flowers are removed, these violas will keep the garden gay with blue all the summer through.

The effect is very greatly enhanced by mingling the untidy, straggling nemophila with the violas. This little pure blue flower, with its white centre, set off by the dark anthers of its stamens, has a great fascination for me. A fitting companion for this little plant is another small annual, Phacelia campanularia, which holds up its dark blue cup-like bells to the sun. Like nemophila, the anthers form the chief decoration of the flowers, but in this case they are white, and the interior of the cup is also decorated by five symmetrically placed white spots.

Digitized by Google

Love-in-a-mist, with its pale blue flowers half hidden in a veil of green, must find some little corner in our garden, for its quaintness and old times' sake.

Though one cannot hope to get on a small scale in the garden that wonderful effect of a pale blue sea given by a field of flax in full bloom, the plant is well worth growing for its dainty pale blue flowers poised on slender upright stems. How many of us connect this plant with "flaxen hair," from the colour of dressed flax, or with linseed oil which is obtained from its seeds?

Apart from the small bulbous plants of early spring, the rock garden cannot boast of very many blue flowers, though the few there are make up in quality what is perhaps lacking in quantity. Both the little spring gentian (G. verna), with its flowers like little blue stars and the much larger stemless gentian (G. acaulis), with its great blue trumpets should both be included. Lithospermum prostratum is to the rock garden what anchusa is to the borders, one cannot say more. Then there is Eritrichium nanum, which Robinson calls the fairy forget-me-not. It is said to be ery difficult to manage. Omphalodes, too, with its ugly name, but lovely blue flowers, must find a shady corner. I had almost forgotten to mention the alpine columbine, an account of which we read in THE GARDEN last April.

THE QUAINT LOVE-IN-A-MIST WITH ITS PALE BLUE FLOWERS ALWAYS LOOKS WELL IN AN OUT-OF-THE-WAY CORNER.

There are also several quite blue veronicas which take their place on the rockery and especially one with bright yellow leaves, which make the flowers look even more blue than they really are.

Turning now to the larger herbaceous flowers of the border, June is the month, *par excellence*, in my garden for blue, for it is then that the lupins are at their best, every shade of blue to the deepest violet, planted all together in a little bed, surrounded by a crazy paved path with steps all on different levels. In the centre of this bed the taller delphiniums rear their stately spikes. Maeterlinck calls the delphinium "the rough larkspur, in his peasant's blouse who thinks himself more beautiful than the sky, looks down upon the dwarf convolvuluses, who reproach him spitefully with putting too much blue into the azure of his flowers." As if that were possible. In another corner the anchusas' intensely blue flowers form an effective background for the pink lupins.

The iris garden, too, has many blue flowers to show at this time of year. We have not space to call them all by name, and perhaps it would be invidious to single out any one for special mention. Several of the Indian poppies (meconopsis) have blue flowers and one must not leave out Jacob's Ladder (Polemonium cœruleum), with its pretty pale blue flowers with their delicate yellow stamens to set them off.

Later comes a whole assembly of herbaceous flowers on the border line of blueness, not blue as compared with either delphinium or anchusa, but quite blue when seen apart from them. Scabious, with the lovely caucasica for those who can grow it, Michaelmas daisies and the whole campanula family—both the larger plants which adorn the borders and the dainty little bells of the rockery.

In tubs on the terrace of the mansion, blue hydrangeas and agapanthus, the blue lily from Africa, are for the wealthy with glasshouses in which to winter these aristocrats of the summer garden.

For the parterre we have the wonderful Salvia patens, another member of the aristocracy too tender to spend the winter out of doors. Then there is the humble little lobelia brought from a coster's barrow to edge a bed on a suburban lawn or to form a pleasing contrast to the geraniums in a town window-box.

Of climbing plants there are several of the larger clematises with blue flowers and a curious little one with bunches of pale blue blossoms, which is Clematis Davidiana.

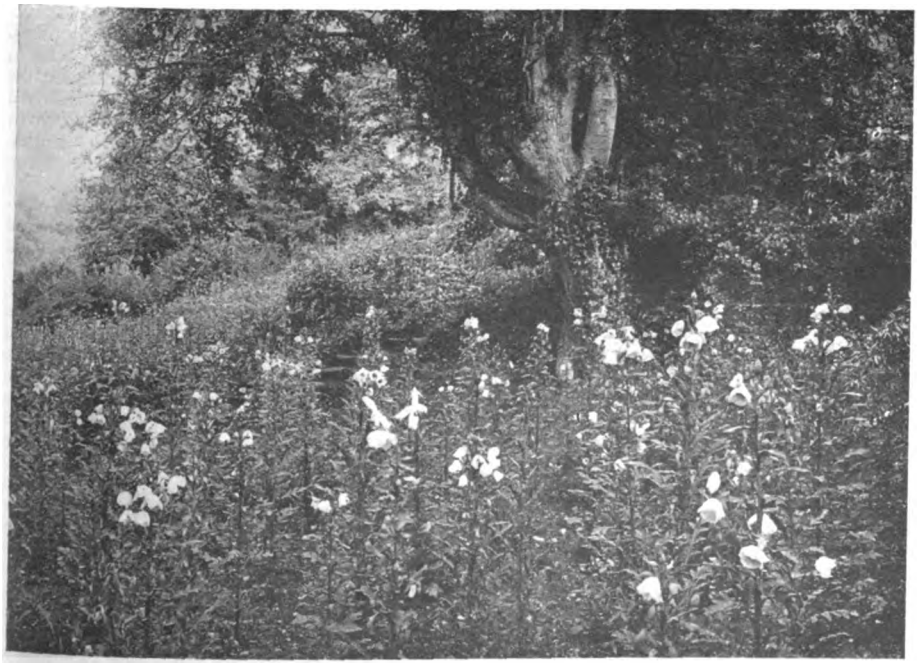
We must not omit to mention the blue convolvulus, with its beautifully shaped cup-like flowers. Unfortunately, like the blue rose, the blue sweet pea has yet to appear, though you will find Mrs. Tom Jones described in the catalogues as "bright delphinium blue"!!

The herb garden is not without its note of blue. Here is borage grown for claret cup and hyssop with its biblical reference:

"And ye shall take a bunch of hyssop, and dip it in the blood that is in the bason, and strike the lintel and the two side posts with the blood that is in the bason."

What shall we say of blue in the garden in winter? Have we not the blue tits flitting from coconut to bare bough and back again, thus keeping a touch of blue in the garden till the spring bulbs come into bloom, when that small patch seems to become a perfect carpet of delicate blue made up with the numerous nodding heads of bluebells.

EDWARD CAHEN.



THE BLUE HIMALAYAN POPPY WHICH IS SO EFFECTIVE IN THE SEMI-SHADE OF WOODLAND.

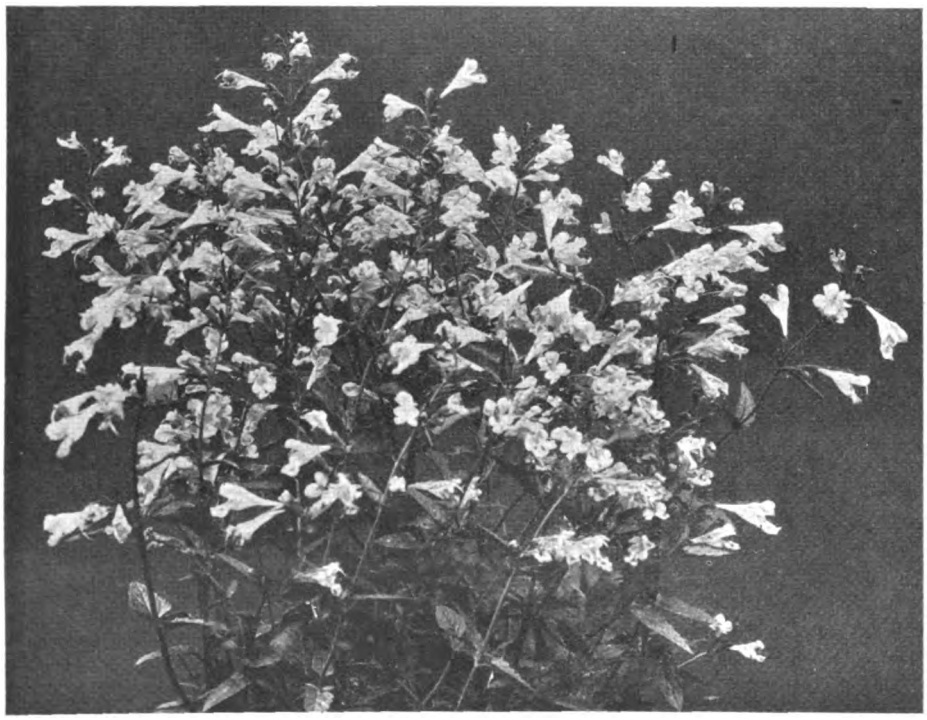
SUMMER FLOWERS AT VINCENT SQUARE

QUITE a dazzling colour display met the eye on entering the R.H.S. Hall at Vincent Square on the occasion of the Fortnightly Show held on July 14th, and the collections staged were fully representative of the season of the year. Two societies, the National Carnation and the Cherry and Soft Fruit Society, held their annual exhibition in conjunction with this meeting, and their exhibits greatly enhanced the general display. Considering the prolonged drought which has been experienced throughout the country in general during these recent weeks, the standard of the exhibits and the tones of colour of the blooms were really excellent. Chief among the floral displays were the magnificent stands of sweet peas with their blaze of colour, while carnations and roses followed not far behind. Herbaceous flowers were much in evidence, and gave that rich vivid colouring which is so warm and pleasing to the eye. The sidalcea was well represented on all the stands where herbaceous flowers were staged, and it certainly strikes one as being a handsome plant for general decorative effect in the garden where a touch of warm colour is desired.



NEPETA PAUL CHANDON WITH LAVENDER BLUE FLOWERS.

Phloxes were well to the fore, and the exhibit of Mr. H. J. Jones once again calls for special mention. He excels with the phlox, as he does with the hydrangea, and many of the varieties, which were laid out in baskets in the form of an oval carpet, were of wonderful shades. Among these we noted Rheinlander carrying large heads of salmon pink flowers with a deeper eye; Snowdrift and Mrs. Ruys, both pure white varieties; Mrs. H. Wood, delicate pink shading to deeper tones in the eye; and Nidar, of a mauve shade toning to white. Delphiniums were also staged, and provided that blue tone required to relieve the brighter shades of the phloxes. Two varieties, Millicent Blackmore and F. W. Smith, looked excellent in tall spray vases at each end of the exhibit.

Messrs. Waterers also showed a number of fine varieties of phlox, among which were Marie S. Jacob (pale lavender pink), Marechal Foch, Evelyn (deep pink) and Europa (white with a mauve pink eye).

An interesting exhibit was that staged by Mr. Ormiston Roy of Montreal of peonies grown in Canada. None of the varieties were named, but several appeared to resemble those on this side. It certainly was not apparent from the fine condition of the flowers that they had withstood a journey from Canada in cold storage. This fact serves as another striking example of how well some plants will carry over long distances uninjured.

Fruit was also well represented, and provided a tempting display. Messrs. Bunyards staged a fine exhibit of cherries, while Messrs. Daniel Brothers showed their new late black currant September Black, and Messrs. Seabrook the well known variety Seabrook's Black and a fine variety of gooseberry (Whinham's Industry). Strawberries and red currants were in the capable hands of Messrs. Laxton Brothers, who were showing such strawberries as Omega and Rearguard and their Laxton's Perfection currants. Many amateurs also contributed to the collection of fruits, along with the East Malling Research Station, which is doing such valuable work in the many fruit problems which beset the grower and cultivator in this country.

The alpines were again rather overshadowed by the wealth of border plants, for their season is shorter in our gardens than in the mountains, where spring creeps up slowly from the valleys and has only just reached the snow line. But all rock plants are not alpine, and the variety in the few exhibits showed that the rock garden need never be without flowers.

Messrs. Tucker showed the oddly beautiful little Campanula Zoysii, with bottle-shaped flowers of lavender blue closely puckered at the lips. In its home in the Julian Alps it is purely saxatile, but in the garden it grows freely in scree mixture and is far less difficult than is generally supposed. Its worst enemies are the slugs, which have a strange and detestable predilection for the rarer campanulas, and for Zoysii most of all. With it were shown Campanula kewensis a hybrid of C. excisa and much cosier, with jauntily twisted petals of violet blue; C. Wockii another hybrid with stiff, grey-green leaves and starry lavender flowers and Anagallis tenella, our rare native bog pimpernel, covering a close green mat with delicate pink cups veined with red.

Messrs. Wood of Ashtead made a very pleasant decoration in cool primrose yellow, white and lavender, with dwarf evening primroses (Œnotheras riparia, Fraseri and missouriensis), white campanulas and a new nepeta, Paul Chandon, which received an award of merit. Nierembergia rivularis was shown covering itself with pearl white cups, which, oddly enough, have the scent of the river mud in which it grows by the La Plata. In our cooler climate it prefers a better drained situation.

Messrs. Reuthe showed a number of campanulas hiding shyly under the semi-tropical shrubs: Campanula Raddeana, beautiful in its deep violet, but inclined to be rather lank and awkward in habit; C. cæspitosa, a very small and charming form of C. pusilla, but not the true plant, which is probably not in cultivation and C. valdensis, dark purple with rather hoary foliage.

Messrs. Waterers showed some pleasant St. John's worts, Hypericum cuneatum, whose mahogany red buds contrast with its glaucous leaves and enhance the golden yellow of its blossoms; and H. olympicum citrinum, a good sulphur yellow form; Campanula turbinata grandiflora, whose flowers are really too large for the plant and look like inverted umbrellas.

In the cherry and soft fruit show, under the auspices of the Fruit and Vegetable Committee of the Kent Branch of the National Farmers' Union, the large numbers of exhibits of cherries gave evidence of the keen interest which growers take in the culture of this choice dessert fruit. A cherry and soft fruit show, such as this, provides opportunity for fruit farmers to discuss questions of mutual interest and does much to maintain a high standard.

The fruit was perfect in condition and excellent both in shape and quality. Cherries, gooseberries and black and red currants were exhibited. Several silver challenge cups were awarded, as well as many prizes. In Classes I and II the Norton Orchards, Limited, won first prizes for cherries, the varieties shown being Bedford Black and Waterloo. The Executors of Mr. W. R. Dixon secured the first prize for black cherries, and Mr. W. F. Wood a silver challenge cup for a basket of Napoleon, and also a first for a fine exhibit of Amber (Kent Bigarreau). The fruit of the last mentioned variety was especially good in shape and colour.

Messrs. G. H. Dean and Co., Limited, exhibited very fine cherries, gooseberries and black currants, for which they received some of the highest awards given. In white cherries they excelled particularly. For a red (sour) variety, Mr. E. B. Gascoyne surpassed the other exhibitors, and the Executors of Mr. W. R. Dixon took the honours for three distinct black cherries.

The gooseberries were enormous in size. A basket of Lancashire Lad won a first for Messrs. Wakeley Bros., and Mr. Sydney Wakeley was awarded a challenge cup for the yellow gooseberry Brighton Mammoth. In Class XIV, for any variety of red currant, Messrs. W. J. and F. O. Thomas received a challenge cup for Fay's Early Prolific, and excellent black currants were shown by Messrs. G. H. Dean and Co., Limited. Sir W. W. Berry was awarded the first prize for raspberries, his basket of Superlative

Digitized by Google

being remarkably good in size, flavour and condition.

Among other exhibits were the following :

ALPINES.—Messrs. E. Dixon.

CARNATIONS AND PINKS.—Messrs. Allwood Bros., John R. Crowhurst, C. Englemann, J. Douglas and C. Herbert.

FRUIT.—C. H. Hooper, tables showing results of cherry pollination trials. Sir Charles Nall Cain, Bt., cherries and raspberries. Colonel B. T. Petre, new black currant.

HARDY PLANTS.—Messrs. T. Carlile, Chalk Hill Nurseries, K. and E. Hopkins, Kelway and Co., B. Ladham, M. Prichard, Rich and Co.. Stark and Sons, Limited, and Mrs. Martineau,

LAVENDER IN TUBS.—Messrs. Lucas and Hill, Limited.

LILIES.—Lieutenant-Colonel Messel.

ORCHIDS.—Messrs. J. T. Bolton, Sanders and Co., and H. T. Pitt.

ROSES.—Messrs. Chaplin Bros., W. Easlea and Sons, T. P. Edwards and J. H. Pemberton.

STOVE PLANTS.—Messrs. L. R. Russell and Co.

SWEET PEAS.—Messrs. S. Bide and Sons, Limited, A. Blandford and Messrs. Dobbie.

VIOLAS.—Mr. W. Yandell.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

SALVIA DICHROA.—This is a half-hardy species, by some authorities considered the same as S. bicolor. The stems are from 2-3ft. high and are square, characteristic of the family. The leaves are ovate in shape and rather long. Numerous flowers are borne in racemes 1ft. or more in length. These are of a bright to pale blue in colour, with the middle lobe of the corolla white, providing a good contrast. It is rather a handsome plant, especially when given full play. Shown by the University Botanic Gardens, Cambridge.

HOYA BELLA.—A rather slender and bushy evergreen shrub 1-2ft. high, and of graceful and attractive habit. The leaves are rather thick and oval in shape. The more or less waxy-looking flowers are borne in umbels. The corolla is made up of five pure white lobes, while the crown consists of five violet, almost boat-shaped segments. As the flowers hang downwards and are hidden by the foliage, much of the beauty of this handsome little species is lost. Shown by Messrs. Russell, Limited, Richmond.

PISTORINIA INTERMEDIA.—This representative, probably more commonly known as cotyledon, of the crassula family is a small succulent herb with more or less of an erect habit, about 9ins. to 1ft. high. The leaves and also the stems are thick and fleshy. The numerous flowers are carried erect in terminal cymes. These are of a dull yellow in colour, with five spreading rather ornate petals. Down the centre of each petal runs a dark crimson dotted line quite characteristic. Shown by Mr. L. Johnston, Hidcote Manor, Campden, Gloucestershire.

HEMEROCALLIS RADIANT.—A tall handsome variety carrying large flowers of a pure shade of golden orange which does not shade away into lighter tones in the throat. The perianth segments were also of good substance with some character about them. Each flower is about 3ins. long and when fully open 2½ins. across. The stems are stiff and erect. Shown by Mr. G. Yeld, Gerrards Cross.

NEPETA PAUL CHANDON.—This is a decorative variety about 18ins. high, carrying numerous two-lipped lavender blue flowers borne on stiff and erect stems. The foliage is light green and provides a good background for the flowers. Shown by Mr. F. G. Wood, Ashtead.

ROSE DAINTY BESS.—The praises of this fine single hybrid tea variety were fully sung in our report of the Rose Show at Regent's Park a fortnight ago. The large single flowers are composed of crinkled and waved petals of a fine shade of delicate pink which is deeper on the reverse side. Shown by Mr. W. E. B. Archer, Ashford.

ORCHIDS.

DIPLOMERIS HIRSUTA.—A native of Sikkim, in the valley of the Teesta, where it is found on sandstone rocks at elevations of about 1,000ft. to 1,400ft. Leaf solitary, bearing stiff, scattered hairs on both surfaces. Flowers pure white, nearly 2ins. long and 1½ins. across. Award of merit. Shown by Messrs. Sanders, St. Albans.

ODONTIODA THIASA VAR. GOLDEN GODDESS.—A finely grown plant with over thirty-two flowers, the segments boldly marked with bright red. Cultural commendation. Shown by Mr. H. T. Pitt, Rosslyn, Stamford Hill.

BRASSO-LÆLIO-CATTLEYA JUPITER VAR. MRS. STEWART.—Not only is this a noble flower, but the present example was brought to a fine state by skilful cultivation. The two spikes each bore a couple of immense flowers of mauve colour, the labellum purplish. Cultural commendation. Shown by Mr. J. J. Bolton, Claygate.

CORRESPONDENCE

VIBURNUMS CARLESII AND BITCHIUENSE.

SIR,—I am grateful to my friend Mr. Grove for setting me right about the relative merits of these two species. It was not, however, from plants of V. bitchiuense at Monreith that I formed the opinion which I ventured to express in favour of V. Carlesii. We have not, and never have had, any of the former species here, though we have, and greatly value, plenty of the latter. I wrote after examining the plants of V. bitchiuense at Kew, which happened to be in flower at the time, and I could detect no tint of rose on the unopened buds. Evidently I must lose no time in acquiring this species.

May I add an apology to Mr. Stern for having taken up his challenge without adequate knowledge of the subject. I lower my lance in salute to him.—HERBERT MAXWELL, *Monreith.*

A PRONOUNCING DICTIONARY.

SIR,—The *Gardeners' Chronicle* is quite right in making the "i" of "erica" long, and your correspondent Mr. C. G. O. Bond is in error in making it short and deriving the word from the Latin *ericius*, a hedgehog. Pliny's name "erica" is simply a transliteration of *ereike*, the Greek name for heath. The diphthong and the occurrence of the word in the Greek poets, *e.g.*, in Æschylus and Theocritus, prove the quantity of the "i" beyond any doubt. The Latin *ericius* is of entirely different derivation.—G. H. ENGLEHEART.

A CLIMBING ROSE.

SIR,—I think the rose described in THE GARDEN of July 4th by M. L., Bournemouth, is one I grow which came from Baveno (Lago Maggiore), where the gardens are full of it. I do not know the name, have never seen it elsewhere in England, and have not observed that it has any lemon verbena-like perfume. If M. L. gives me her address I will send her a specimen when it comes into bloom. It grows easily in Sussex. I have given it the protection of a wall and intend to try it more in the open when I have other plants. The two I have now are cuttings I struck from the original plant from Baveno.—DALLING.

ALUMINIUM SULPHATE AGAINST SLUGS.

SIR,—In discussing the use of sulphate of aluminium against slugs, some experiments reported in the Journal of the Royal Horticultural Society are referred to as the Wisley experiments. May I point out that these experiments were not made at Wisley, but were the work of the author of the paper, Mr. W. E. H. Hodson.—FRED. J. CHITTENDEN, *Director, R.H.S. Gardens, Wisley.*

A REMEDY FOR EARWIGS.

SIR,—Your correspondent, L. P., may clear his plants of earwigs by using a one in three thousand strength solution of perchloride of mercury, either as a spray or distributed through a watering can. It is made by dissolving 120 grains of mercury perchloride and the same weight of ammonium chloride in 5 gallons of water. Care needs to be exercised in the use of mercury perchloride, for the salt is very poisonous. But, while it is deadly to both earwigs and slugs, it is harmless to plants, used in the strength given.—WM. TAYLOR.

TRENCHING OF CLAY SOIL.

SIR,—I did not at first intend to add to my recent correspondence on the above subject, but after reading the note in your issue of the 23rd ult. I would like to say that, after Mr. Beckett's qualifications and elaborations, he and I are not so far divided in opinion as his original article would suggest.

If trenching can be done after the winter rains are over, and plenty of opening and enriching material can be added before a crop is planted or sown, I by all means second Mr. Beckett's "Trench, trench, trench."

But how many places at present permit of such work in spring—say March or April? Why, it takes most gardeners every minute to get ground decently wrought a single spit, along with the hundred and one other jobs which fall to be done at that season.

Most trenching and double digging is done in October and November, before the rains begin, as that is the only season the average gardener can find time for it.

Also, the necessary material for improving the sterile soil brought to the surface has a limit in most places, at least in my experience; hence my reason for advising caution.

Perhaps you will allow me to say that I am greatly surprised that so little interest seems to be taken in this, one of the most important of garden operations. I expected that many gardeners would have given their experience on one side or the other.—J. H.

CRINODENDRON HOOKERI.

SIR,—Taking the above name as given at Chelsea, I would like to mention some of the names which have been given to it by botanists and others. Besides the above spelling, it has also been rendered as C. Hookerianum. Only two species seem to be known, belonging to the lime tree family (Tiliaceæ), namely, Tricuspidaria lanceolata and T. dependens. The former is the name adopted as the oldest or correct one for the plant under notice at Kew. Tricuspidaria refers to three small points of the flower, But these points are conspicuous only in T. dependens, which would seem to have been the first species described: and a pale-flowered inconspicuous one it is by comparison with its more august relative. I have known T. dependens to be taken for the better plant in a garden, until it flowered and annoyed its owner.—J. F.

THE SALTAIRE SHOW

THE nineteenth annual show of the Saltaire, Shipley and District Rose Society was held on July 14th and 15th. at Roberts Park, Saltaire, in delightful weather, and it attracted a large attendance. Three large marquees were filled with choice exhibits, among which roses, sweet peas, carnations, pansies and violas, and rock gardens, predominated. The marquees were spacious and remarkably cool, considering the summer-like conditions, and everything bore a neat appearance. The public were able to see all the exhibits in perfect comfort.

One marquee was almost exclusively devoted to the rock exhibits. Messrs. Mackenzie and Sons of Ilkley were awarded two large gold medals for a charming rock garden which contained a varied display of alpines and shrubs and which was entered through a rustic arch. In the centre there was a streamlet crossed by a miniature rustic bridge.

Messrs. Conway's of Halifax had a rock garden flanked by a neat formal garden, surrounded by a border of pink verbenas and central beds containing polyantha roses, marguerites and hydrangeas.

Other good rock exhibits were those of Messrs. Kershaw's of Keighley (in which we noticed a fine crazy path), Messrs. Rashley and Co. of Mytholmroyd, and Mr. Gardner. In the latter exhibit there was a miniature tennis court and a floral surround.

In another marquee Mr. Frederick G. Wood, Mr. R. V. Roger and Messrs. Maxwell and Beale all had interesting collections of alpines set out on tables; but the feature of this tent was a pretty Old English formal garden, constructed by Messrs. Backhouse's Nurseries, Limited, York. It was semicircular in form, with a curving, low wall, below which in the centre was a miniature statue of the god Pan. This original and neat exhibit deservedly won the President's large gold medal.

ROSES.

There were many fine trade exhibits, and the principal prize-winners were Messrs. Alex. Dickson and Sons, The Donard Nursery Company, Messrs. Bees, Limited, Mr. Elisha Hicks, Mr. Henry Drew and Mr. George Burch.

In Messrs. Dickson's stands we noticed the following varieties as being particularly good: Scarlet Glory, Shot Silk (exceptionally fine), Betty Uprichard, Lady Inchiquin, Dame Edith Helen, Richard E. West and Fred. J. Harrison.

The Donard Nursery Company had fine specimens of Margaret Dickson Hamill, Clara Curtis, J. G. Glassford and Marjorie Bulkeley.

Messrs. Bees, Limited, showed Ophelia, Golden Emblem, Mme. Herriot, Mrs. Henry Morse, Nellie Parker, The Queen Alexandra Rose, and Independence Day.

Mr. Hicks had some very fine blooms, and his best varieties were W. F. Dreer, Los Angeles, Lady Inchiquin, Golden Emblem, Clovelly, Johanna Bridge, Betty Uprichard, Argyle and Florence H. Veitch.

In the amateur classes Mr. Cuthbert Dixon of Sheffield was a prominent winner, and among the local amateurs Mr. Harold Mitchell of Bradford was awarded first prize in all the principal classes. Mr. W. A. Simpson-Hinchliffe won the prize for the premier bloom in the Show with a very fine specimen of Mrs. Foley Hobbs.

In Mr. Mitchell's stands, Mrs. Foley Hobbs, Mrs. Henry Bowles, Edel and Caroline Testout were specially good; and in the other amateur exhibits, Willowmere, Lady Inchiquin, Mrs. C. Lamplough, Gladys Holland, Mrs. Henry Morse, Lady Ashtown and J. L. Mock were notable varieties.

Mr. G. C. Waud, in addition to a fine display of roses, also had some very fine carnations and sweet peas.

OTHER FEATURES.

It was said that there has never been a finer display of perpetual carnations seen in the district than the magnificent exhibit put up by Mr. Engelmann. It is doubtful if Mr. Engelmann has ever had his scarlets in finer colouring, and some of the varieties were positively dazzling. Tarzan, Laddie, Red Laddie, Saffron, Dainty and Spectrum were all outstanding kinds.

There were many fine vases of sweet peas in the competitive classes, and Sir Randolph Baker (gardener, Mr. A. E. Usher) secured the chief prizes. Some of his best vases were those of Picture, Tangerine, W. J. Unwin, Wembley, Austin Frederick and Powerscourt. In the local amateur classes, besides Mr. G. C. Waud, the exhibits of Mr. Stephen Shackleton were very good.

Pansies and violas, in spite of the drought, were well shown. Mr. A. W. Upton won first prize for a display of violas, in which the following varieties were especially good: Admiral Jellicoe, Mrs. Andrew Stevenson, Mrs. J. Ritchie, William Hattersley, Milton Jumbo and Annie Hamilton. Mr. J. Wood was awarded first prize for a neat table decoration of violas.

The pansies and violas staged by Mr. Herbert Bairstow were of high quality and secured for him all the premier prizes.

His stand of twenty-four violas included Admiral Jellicoe, Mrs. W. Hunter, Jenny Simpson, James Blair, Nancy Harrison, Annie Hamilton, Peggie Ramsey, William Barr, Edith Bastock and Mrs. J. McEwan. His twenty-four fancy pansies included Mrs. Andrew Frater (specially good), Argyle, Alex. Lister, Miss Nellie Thomson, A. J. Balfour and John Whiteford.

In the classes for six blooms (one variety only), Mr. Bairstow won first prizes with Betty Bishop, Malcolm Milner, Admiral Jellicoe and Annie Hamilton.

SWEET PEAS AT WESTMINSTER

UNDER the auspices of the National Sweet Pea Society, the annual exhibition of sweet peas was held at the R.H.S. Hall on Thursday and Friday last, July 16th and 17th. It is now twenty-five years since the inception of this Society and year by year a steady improvement has been recorded, till on this last occasion all previous shows were overshadowed. A high water mark of excellence was reached, which will be hard to surpass, if not to equal. It was probably the finest show of sweet peas which has ever been seen at Vincent Square and great credit is due to the Committee, especially the Secretary, Mr. A. C. Bartlett, whose untiring energy and enthusiasm has made this possible. Almost all the trade growers were represented, while in the amateurs, classes, the entries were numerous and the competition very keen.

TRADE CLASSES.

Among the trade growers, interest centred round the classes for the Bath and Eastbourne Cups, and the high standard and general excellence of the exhibits was most marked. In the Bath Cup Class, almost all our leading sweet pea firms were represented, and it fell to Messrs. Robert Bolton and Son of Halstead to carry off the Cup, along with a large gold medal. Their stand, although it appeared rather crowded, had a really fine display of colour, the shades of the blooms being greatly enhanced by the decorative trimmings of asparagus. It seems invidious to single out names, but those varieties which attracted our attention were Charming, Mrs. Tom Jones, Wizard, Supreme and Peggy, a novelty for 1926. The blooms were all in excellent condition considering that they were all grown out of doors without any protection or shading from the spring sunshine.

A large gold medal was awarded to Messrs. Sutton and Sons, Reading, who had a well arranged stand, in which three overhanging baskets, containing Dignity, Sunset and Hebe were conspicuous. The background consisted of four spray vases filled with Sutton's Giant White, Field Marshal (deep crimson), and the scarlet Pimpernel. Again the colour was rich and pure and the quality of the individual flowers excellent.

Mr. J. Stevenson of Wimborne staged a well balanced exhibit, in which the notable varieties La France, Cynthia, Diana and Hebe were employed to form a light toned background to the brighter and deeper shades of such sorts as Charming, Venus and Coraline. The high standard reflected great credit on the raiser in his cultivation, which was acknowledged by the award of a silver-gilt medal.

Messrs. Dobbie and Co. of Edinburgh, whose name is famous all the world over in connection with sweet peas, staged a most attractive display, consisting of a number of varieties, such as Grenadier, Sunset, Hawlmark Pink, all in the first quality of excellence. The shades of colour were good, while the size and quality of the blossoms were beyond reproach. The reputation which this Scottish firm has already established for themselves in connection with sweet peas should be greatly added to by this display, which received a large gold medal.

Another well set up exhibit was that arranged by Messrs. E. W. King and Co., Coggeshall, which was awarded a large gold medal. Such varieties as Pimpernel, with baskets of Patriot, Britannia, 2 L O and Seedling were included in the stand and all looked exceedingly handsome.

A gold medal was awarded to Messrs. Ireland and Hitchcock for their stand, which was composed of such sorts as Mauve Prince, Royal Scot, Lord Lascelles and Mascott's Ingman. All the varieties were in really fine condition considering the warm, dry weather.

Mr. A. Blandford, West Horsley, made use of the overhanging baskets, in which were arranged Valentine and Daisybud, both of almost a similar shade of blush pink. Other sorts included Austin Frederick Improved, Wild Rose and La France, the latter two showing up well against the darker tones of Warrior. A silver medal was awarded this exhibit.

In Messrs. Daniel's tastefully arranged stand such varieties as Picture, George Shawyer, Rosy Morn, Jack Cornwall V.C., were outstanding. The blooms were of good size and colour and fully deserved the silver medal awarded to their exhibitors.

In competition for the Eastbourne Cup, Messrs. R. Bolton and Sons again added to their already long list of successes by winning the Cup and a large gold medal with a most attractive and meritorious exhibit, which showed the merits of the individual varieties off to distinct advantage. The colour scheme was also to be commended. The spray vases of Royal Pink, Grenadier and Wizard used to overshadow the other varieties, were excellent, and their deeper tints were to some extent relieved by the clean, light shades of Ivory Picture and Matchless. Other sorts which were well shown were Gold Crest, Tangerine Improved, Blue Bird, Picture and Peggy.

Digitized by Google

Messrs. Sutton once more employed overhanging baskets filled with Lucifer, Picture and The President Harding, in their exhibit in this class, which received a large gold medal. Huge spray vases of Mrs. T. Jones (of a good colour), Mammoth, Royal Scot and Powerscourt were also to the fore as a background to such sorts as George Shawyer, Hawlmark Pink and Celeste.

Gold medals were awarded to Messrs. Dobbie and to Messrs. Ireland and Hitchcock for their excellent displays, the former firm including really fine blooms of Miss California, Mrs. T. Jones, Picture, Ruby, Elegance and Charity, relieved to some measure by well placed vases of Constance Hinton: while the latter staged large vases of Matchless, Powerscourt and Wizard, along with many other well grown blooms.

Messrs. Carter and Co. of Raynes Park, although they did not receive an award, had a tastefully arranged exhibit in small baskets, such varieties as Royal Scot, Diana, La France, R. F. Felton and Hebe being represented.

AMATEURS' CLASSES.

Although the trade was well represented at the Show, yet the principal feature was the large number of amateurs who entered for the different classes, and such is to be highly commended. The Society exists principally for the amateur, to assist him in the raising and growing of sweet peas, and it is most gratifying to see the results of their efforts in the increasing number of amateurs who are coming forward every year to take a place in the competitive classes. Prizes cannot be given to all, and those who have gone away empty-handed must do better in the future. In the various classes the entries were numerous and the exhibits were of a high standard, leading to a very keen competition. The majority of the blooms shown were of good quality and colour and indicated that the amateurs were almost as highly skilled in the growing of the certain varieties as the raisers themselves.

The *Daily Mail* Challenge Cup went to Mr. T. W. Franks, Tonbridge (gardener, W. Humphrey), who, in his twelve vases of distinct varieties included Tom Sykes, Pimpernel, Rosy Morn, Wizard and Powerscourt, all in fine condition. In addition to the Cup, he was also made the recipient of £20 by Messrs. E. W. King, as he included three of their novelties in his exhibit. Major General R. L. Mullons, Colchester (gardener, T. Baines), was a close second, with such sorts as Wild Rose, Royal Sovereign and Tom Sykes, among others, while the third prize fell to Dr. G. Cole, Beeston, Notts, who staged Lord Lascelles, Matchless, Gloriosa and others.

The Sultan Cup was awarded to Lieutenant-Colonel Sir R. Baker (gardener, Mr. Usher), who showed, in his eighteen vases of distinct varieties, such sorts as Charming, Valentine, Royal Scot and Royal Sovereign, the quality of the blooms being excellent. Major Geoffrey Lubbock, Pangbourne, Berks. (gardener, J. B. Lowe), was second, with fine blooms, among which were Hawlmark Pink, Field Marshal, Jean Ireland and Mrs. Arnold Hitchcock.

In the class for six vases of distinct varieties, Mrs. V. M. Williamson, Canterbury (gardener, W. Langsdon), received the Cory Cup, the premier award for her excellent exhibit, which included fine blooms of Hebe, Charming, Royal Sovereign and Powerscourt. Mrs. Shirley Woolmer followed a close second, including Mrs. Tom Jones, which was judged as the best bunch in the Show, while Mr. W. Barrett, Bray, Co. Wicklow, was third with really good blooms of Elegance, Gladys and Annie Ireland, considering that they had been cut on the Tuesday and had with stood a fourteen hours journey.

Lieutenant-Colonel Sir R. Baker was successful in winning the gold medal of the Society for his collection of twelve vases of British raised varieties, while Lieutenant-Colonel H. Laurence Scott was a good second, with Mrs. Tom Jones, La France and Hebe among others.

Mrs. Williamson added to her triumphs by winning first prize in the class for three distinct colour varieties. Her winning three were Constance Hinton, Mrs. C. W. J. Unwin and Mascott's Helio. Mr. Arthur Hutton was second, while Mr. Allan Gibbs obtained the third prize.

The Monro Challenge Trophy, for the best twelve vases with not less than six varieties, raised or introduced by the exhibitor, went to Messrs. Thos. Cullen and Sons, Witham, who staged, among others, Pink Perfection, Blue Bird, Mermaid and Crusader, while Messrs. E. W. King, with 2 L O, Britannia and others, were second, and Mr. H. J. Damorum was third.

In the President's Class with three vases illustrating colour schemes, the first prize was awarded to Miss Russell, whose vases were most attractive. Mrs. F. W. Franks was second, and Mr. A. Johnson, third.

Messrs. E. W. King reversed the order of the things in the seedling class, when they were first with Britannia, Giant Mauve and Brenda, three varieties not yet in commerce, and Messrs. Thos. Cullen, were second.

The former firm were also successful in the class of one vase of a variety not yet in commerce. With 2LO they were first, with Messrs. Ireland and Hitchcock runners-up with Firefly.

In the raisers' classes, Mr. J. Stevenson was first with Charming, Coraline, Venus and Cynthia, with Messrs. Thos. Cullen second and Messrs. E. W. King third.

In the class for the E. W. King Cup, for which there were a large entry, Mrs. Arthur Hutton was a praiseworthy winner with blooms of Grenadier, Royal Sovereign and Geo. Shawyer. Sir Joseph Tichborne was second, with Captain R. B. Brassey and Miss Russell third and fourth respectively.

Still another cup, the Burpee Cup, was awarded to Sir R. Baker, when he was first with six varieties which have not been in commerce for more than one year. He included Miss California, Mammoth, Sunshine and Coraline. Mr. H. D. Tigwell was a worthy second.

In the District Classes, Mr. Allan Gibbs was a successful first for the Western Counties and South Wales, while Mr. T. W. Franks occupied a similar position in the Southern Class. Entries were poor in the Scottish and Irish Classes, and Mr. J. W. Jeffrey of Selkirk was first in the former and Mr. W. Barrett in the latter. The reverse was the case with the Midland Counties, where the entries were large, Captain R. B. Brassey being successful.

Few affiliated societies put up an exhibit for the challenge shield awarded for twelve distinct varieties, and this was won by the Pangbourne and District Gardeners' Association by a well set-up exhibit.

In the single bunch classes there were numerous entries and many varieties were shown. Miss Russell was the most successful in these classes, lifting eight first prizes.

In the special division for amateurs, Mr. F. T. Rogers won the Hawlmark Challenge Cup, while Mr. Arthur Leigh won a silver cup. Mr. Simon Richards was awarded *The Amateur Gardening* Challenge Cup, with such noteworthy varieties as Charming, Mascott's Purple and Mrs. A. Hitchcock. In the classes for small growers, Mr. H. W. Lewington received the cup for twelve distinct sorts, while the Walter Voss Challenge Cup went to Mr. J. Randall.

In the floral decoration classes, the standard might have been higher. Foliage was too much in evidence, while in many cases too much attention was given to the actual vases, rather than to the flowers themselves. The baskets, however, were tastefully arranged and the first prize went to Mrs. L. Fortescue.

There were a few other classes of which, unfortunately, through lack of space, we are unable to give an account.

MESSRS R. BOLTON'S EXHIBIT WHICH WAS AWARDED THE EASTBOURNE CUP.

FLOWERS AT THE ROYAL SHOW

FROM a small beginning the horticultural section of the Royal Show has now become an important event. In consequence of the liberal prizes offered, the herbaceous section display excels anything ever seen in London, and with premiums amounting to £75, offered in three prizes, no other show, probably (and certainly not the premier horticultural society), can bring out such fine groups.

In the group of Messrs. Bees, which secured the highest award, delphiniums predominated. Cambria is a metallic blue, and Willie O'Breen a pale shade of blue. The yellow Verbascum vernale was very telling. In the group of Messrs. Artindale (Sheffield) that fine Eremurus Bungei was a good shade of yellow.

Iceland poppies, and especially Giant Orange, were bright in Messrs. Gibson's (Leeming Bar) fine display and the ever popular erigerons, which are sometimes called " Summer Michaelmas Daisies," were fine in Messrs. Harkness' group, also from Leeming Bar.

One of the most beautiful of herbaceous plants, the lovely blue Scabiosa caucasica, and its varieties, figured prominently in the exhibit from Messrs. Jarman and Co. (Chard).

Roses which are best for the garden are not always to be seen at a show, but a judicious selection of not always the largest and best formed could be made from Souv. de Georges Pernet, rose pink flushed with apricot red; Souv. de Claudius Pernet, bright yellow; Betty Uprichard, old rose with darker reverse to petals; Lady Inchiquin, a unique shade of orange vermilion; Los Angeles, salmon flushed with apricot orange; Etoile d'Holland, crimson, sweetly perfumed; and Clarice Goodacre, a dainty biscuit white. These were displayed by Messrs. Bees, Limited, Liverpool; Thos. Robinson, Nottingham; W. and J. Brown, Peterborough; A. J. and C. Allen, Norwich.

Shot Silk, a pink flushed with a scarcely perceptible shade of yellow, was the best in Messrs. Alex. Dickson's group. The combination of a fine garden rose with the form of exhibition standard is found in Lord Charlemont, a deep crimson, shown in Messrs. B. R. Cant's group.

CARNATIONS.—No show at any time of the year is now without carnations, and just at this date the old border types are at their best. Border Yellow, Bookham Rose and Salmon Clove, were three of the best seen in Mr. Horace Lakeman's collection from Thornton Heath. A miniature garden on the ground contained Messrs. Allwood Bros. Dianthus Allwoodii from Haywards Heath; they also had Edward Allwood massed in a telling way, included in their collection of perpetuals. The crimson carnation, Topsy, was fine in Mr. C. Engelmann's display from Saffron Walden.

FORMAL GARDENS.—Much anent the arrangement of a garden may be learnt by a visit to one of these shows. Thus, an ideal crazy paving surrounding a cool pool was arranged by Mr. C. H. Taudevin of Wollaston, Cheshire, and a still more extensive lay-out by Messrs. Kent and Brydon from Darlington included a terrace walk with large water garden flanked with bamboos, lilies, delphiniums and other herbaceous plants.

Smaller rock gardens were arranged by Messrs. Maxwell and Beale, and Mr. R. V. Rogers. An instructive garden was made by the Aldersley College near Chester. Those who are fond of a dainty flower in this class will find the miniature mauve Campanula linifolia, which was in the exhibit of Messrs. Bowell and Skarratt, a charming addition.

GROUPS OF PLANTS.—The masterly skill of arrangement employed by Messrs. Cypher, W. Holmes and T. Petch, were alone worth a visit to the show to see. The combination of orchids and foliage plants was made to give the maximum light effect and show combined.

Sweet peas with perfume are mostly found among mauve and duller shades, but the orange salmon Gold Crest in Mr. Robert Bolton's group, the reddish salmon Royal Sovereign in Mr. E. W. King's group, and the soft mauve Powerscourt in Mr. J. Stevens exhibit were outstanding. The mauvy blue variety " Orchid " was conspicuous in Messrs. Dobbie's group.

Some gorgeous begonias came from Messrs. Blackmore and Langdon. A good selection would be Nurse Cavell, a pure white; Mrs. Richard Caulfield, rich salmony rose; Mabel Langdon, pale salmon; Sir Henry Wilson, scarlet; Rayon d'Or, orange.

Strawberry Waterloo, nearly purple, with Omega, a new late variety, were included in the group from Messrs. Laxton Bros.

MISCELLANEOUS EXHIBITS.—Messrs. Suttons had a tent all to themselves, with patches of various types of grasses for golf courses. Inside the main tent sweet peas, larkspurs and Clerodendron fallax were well displayed.

The fragrant Phlox Etna, a reddish salmon, pentstemons, and the brilliant dwarf Dahlia Coltness Gem, were sent from Hawick by Mr. John Forbes. From The Donard Nursery, Newcastle (Ireland), some choice shrubs included the brilliant Tricuspidaria lanceolata, and a much neglected, but easily grown, shrub, Spartium junceum, popularly known as Spanish broom.

A further tent, away from the rest, housed the specialities of Messrs. Dicksons, Chester. Roses and herbaceous plants, fruit trees and floral work were a varied display from a firm noted for the great variety of its products.

A fine strain of streptocarpus and gloxinias, arranged with caladiums, crotons, came from Messrs. John Peed and Sons.

A collection of the more rare herbaceous plants, as well as such showy subjects as kniphofias, phlox, campanulas, etc., were sent from Christchurch by Messrs. Maurice Pritchard and Sons.

One naturally associates sweet peas with the name of Henry Eckford, Wem. His flowers were of their usual fine standard and included some fragrant varieties, which the public appreciates more to-day than ever.

THE WINDSOR ROSE EXHIBITION

ON July 11th the Windsor Rose Society held its Annual Show on the slopes of Windsor Castle, so thoughtfully and considerately thrown open by His Majesty. In past years the Show was usually held on the last Saturday in June, but for good and sufficient reasons the Committee decided upon a later date this year, and gained thereby in that they had the finest Show for many years, and the perfection of the arrangements represented an enormous amount of hard work by the hon. secretary, Mr. J. Harding.

The chief attraction is the King's Cup, which is offered annually for the best forty-eight distinct roses and is open to all England. In the past it has been won four times each by Messrs. B. R. Cant and Sons and by Messrs. D. Prior and Son, and twice by Messrs. Alex. Dickson and Sons. This year's winner proved to be Messrs. Frank Cant and Co., who staged an excellent collection of such sorts as Mrs. Wallace H. Rowe, Mrs. Foley Hobbs, Mrs. Elisha Hicks, Dean Hole, Bessie Brown and Premier. Messrs. B. R. Cant and Sons were a good second in the champion class, and they had fine blooms of Mrs. Henry Bowles, Mrs. G. Marriott, Bessie Chaplin and George Dickson; while Messrs. D. Prior and Son were third.

Mr. George Prince was the most successful exhibitor of eighteen tea or noisette blooms, and his very fine collection included fragrant specimens of W. R. Smith, Maman Cochet, White Maman Cochet, Mrs. Foley Hobbs, Lady Plymouth and Mrs. Hubert Taylor. In the second prize exhibit of Mr. E. J. Hicks Maman Cochet, W. R. Smith and Mrs. Foley Hobbs were particularly good.

Competition was very strong in the class for trios of twelve varieties, and Messrs. B. R. Cant and Sons had a splendid exhibit of such sorts as Captain Kilbee Stuart, H. V. Machin, George Dickson and Mrs. George Norwood. Messrs. D. Prior and Son were second, and they included Venus, Mrs. R. D. McClure, Martha Drew and Mrs. G. Marriott of great excellence.

The best twelve blooms of any hybrid perpetual or hybrid tea rose were magnificent blooms of Mrs. Elisha Hicks staged by Messrs. F. Cant and Co.; while Mr. C. Gregory was second with a splendid dozen of Candeur Lyonnaise. The similar exhibits of any tea or noisette rose were also of high quality, and Mr. George Prince was the first prize winner, with Mr. E. J. Hicks second and Messrs. D. Prior and Son third, all with Mrs. Foley Hobbs. Mr. George Prince was also the most successful exhibitor of twelve blooms each of a crimson and a white rose in two baskets.

The best of the four exhibits of twelve bunches of decorative roses was set up by Mr. Henry Street, who had lovely vases of Lulu, Sunstar, Ophelia and Golden Emblem. Messrs. A. Warner and Son were second with Los Angeles, Isobel, Ophelia and similar varieties.

AMATEURS' CLASSES.

Equal in importance with the King's Cup to the trade is the Windsor Challenge Cup to amateur rosarians. It is for open competition, and this year the greatly desired distinction of winning the honour fell to Dr. R. C. Turnbull, Colchester, who had among his superb twenty-four blooms the best rose in the whole of the Show. This was a delightful specimen of Mrs. C. Lamplough. He also showed George Dickson, Mrs. H. R. Darlington, Cleveland, Mrs. George Marriott and F. N. Thompson of great merit. Mr. F. H. Fieldgate, also of Colchester, was a worthy second in this important class, and his board of fine varieties included Louise Crette, Her Majesty, Avoca and Coronation. Dr. Turnbull also won the first prize for trios of six varieties with a superb collection, and Mr. Fieldgate was again a good second. Dr. Turnbull added to his triumphs by showing the finest six tea roses, and he included lovely blooms of Mrs. Campbell Hall, Maman Cochet and White Maman Cochet; while Mrs. Henry Balfour was second.

In the local classes, Mr. J. Tiller had the best collection of roses, and he included Lady Inchiquin, Mrs. G. Marriott and George Dickson of great excellence.

The splendid quality of the many exhibits of sweet peas augured well for the success of the forthcoming annual show of the National Sweet Pea Society. The Prince of Wales' Cup was again won by Sir Randolf

Digitized by Google

Baker, Blandford, with fifteen magnificent vases of Wizard, Wild Rose, Powerscourt, Warrior, Constance Hinton and Mrs. Arnold Hitchcock. Major C. B. Krabbe, Calcot, Grange, Reading, was a good second in this large class, and he showed beautiful vases of Bunty, Wizard, Hebe and Purple Perfection. Sir R. Baker also showed the best twelve bunches in the open amateurs' classes, and with six equally fine vases won the Edward Webb and Sons' prize for sweet peas.

The trade exhibits were a magnificent feature of the Show, and Mr. Elisha J. Hicks again won the Lady Peter Cup with a splendid exhibit of roses. Messrs. A. Bide and Sons had sweet peas; Mr. Charles Turner and Mr. J. C. Allgrove showed delightful groups of border flowers; Mr. J. H. Pemberton, Messrs. Brinkman Brothers, Mr. G. Gregory and Mr. C. H. Murrell staged roses; while Mr. W. Yandell set up one of the largest collections of lovely violas ever seen.

BORDER CARNATIONS

THE two shows held by the National Carnation and Picotee Society during the last week were most successful owing to the untiring energy of the committee. On July 14th some fine blooms were exhibited at the Royal Horticultural Society's Hall; and on July 16th an interesting show was held in the Carpenters' Hall. The latter is the first show which this Society has held in the City during the forty-seven years of its existence. After a few words spoken by the President, the show was opened by the Lady Mayoress, who very kindly presented the challenge cups won at the previous show. The representative of Mr. James Douglas of Bookham fame received the Cartwright Challenge Cup; Miss Shiffner of Lewes the Edmund Charrington Challenge Cup; and Mr. H. A. Knapton of Orpington the Martin Smith Memorial Cup.

The quality of the blooms exhibited was excellent, the colours clear and bright and the foliage healthy. The selfs were not so good as many of the fancies, which were truly of outstanding merit. Among the amateurs who carried off the greatest number of prizes were Miss Shiffner, Mr. E. Charrington of Limpsfield, Mr. James Fairlie of Acton, Mr. H. A. Knapton, Mr. F. W. Seymour of Finchley and Mr. S. Williams of Chipstead.

In the first division (open), Messrs. Lowe and Gibson deserve special mention: they were awarded a first in every class. Ganymede was the best white ground picotee, Togo the best yellow ground picotee, and Steerforth the premier clove-scented carnation. Fine specimens of Lieut. Shackleton, Prospero and May Murray were shown by this firm. Messrs. Torrance and Hopkins also had some good carnations in this division, including David Herbert and Paladin. In the amateur classes, Mr. F. H. Seymour had a first prize exhibit, and of the three fancies Paladin was superior in shape and quality. Mr. E. Charrington showed St. Claire Amos, and, near by, Mr. F. H. Seymour had some beautiful blooms of that charming orange yellow variety, Elizabeth Shiffner, and the fragrant Burgundy clove. Miss Shiffner, one of the most successful exhibitors of the Society for some years, took a first prize for the pale cerise pink, Mrs. R. P. Smith.

In the third division, in which only members who grow fewer than 300 plants in pots were allowed to exhibit, Mr. R. S. Bowra of Golders Green won two first prizes, Bookham Rose, Border Yellow and Highland Mary being the best varieties which he exhibited. In Class 21, Mr. H. A. Knapton showed Santa Claus, a yellow ground picotee with a narrow edging of purple. A vase of three dissimilar self varieties and another of three blooms of clove-scented varieties won prizes for Mr. S. Williams. Mr. H. A. Knapton was particularly successful in this third division.

Blooms from plants grown and flowered in the open border were exhibited in the fourth division. Primrose Dame and Yvonne Thomas, Lieut. Shackleton and Highland Mary, shown by Mr. F. W. Seymour, were awarded first prizes. Mr. H. Spicer of Hitchin had some lovely flowers of Steerforth, and Mr. G. D. Murray of Worcester Park won a first prize for a seedling carnation.

The three trade exhibits were staged by Messrs. Allwood Brothers, Mr. James Douglas and Messrs. Lowe and Gibson. Many of the old varieties were seen on these stands. Mr. James Douglas had a large collection of new and old varieties, including Kelso, Lieut. Shackleton, M. F. W. Seymour and Elbor. The last two varieties gained first-class certificates on July 14th. Messrs. Lowe and Gibson had many good fancies and some excellent novelties which should soon become very popular and were well worth taking note of. Most noticeable of the varieties from among the whole exhibit were Viceroy, Mr. Edmund Charrington, Myrtle Pettigrew, Joan Lowe and Dr. Raymond Crawford.

OBITUARY

MR. E. CHARLES BUXTON.

IT is with the deepest regret that we have to announce the death of Mr. E. Charles Buxton of Coed Derw, Bettws-y-Coed. Though he had attained the ripe age of eighty-seven, he was still working in his beautiful garden when he was struck by the intense heat, passing peacefully away a few days later, *i.e.*, on the 11th inst. Though he was not a prominent public figure in horticultural activities, Mr. Buxton was widely known, large numbers of people at one time or another having visited his wonderful garden. He was, moreover, such a voluminous letter writer and frequent contributor to the garden press on matters pertaining to most phases of horticulture, that few men of his generation could claim to have enjoyed a more varied and extensive circle of friendship.

To the average gardener of to-day and to generations to come, the memory of "E. C. B." will be kept alive by the lovely clear blue form of Geranium Wallichianum, by Thymus serpyllum aureum, the lemon yellow Anthemis tinctoria, the very dwarf Aster dumosus and a distinct form of Lychnis viscaria. But to these and other excellent plants which bear his name one might add many which, if they did not originate in the Coed Derw gardens, have been treasured and saved from oblivion by their devoted owner. Among the former is that delightful little unnamed white geranium (not the albino Herb-Robert), Dianthus Woolley Dod, Veronica peduncularis and Rhododendron cheiranthifolia. The beautiful pure white Lamium Orvala alba was one of Mr. Buxton's latest introductions, and there is no doubt that the fine form of Cotoneaster horizontalis, with perfectly flat, prostrate branches and practically identical with that now listed as C. h. var perpusilla, appeared as a seedling at Coed Derw before the latter variety was sent in from Tibet. Another plant of the highest merit which first saw the light at Bettws-y-Coed is a particularly good form of Sedum spathulifolium, with blood crimson leaves.

If the passing of Mr. E. Charles Buxton means that the gardening world is the poorer for the loss of one of that distinguished band of worthies which have linked the days of fifty and more years ago with our own, one also craves the honour of paying a tribute to the memory of one who was, above all else, a grand old English gentleman of a type that is fast vanishing from among us.

Temporary Trial Ground.—The N. of E. Horticultural Society has been granted the use of a plot of land, one and a half acres in extent, situated on the Harlow Moor, at Harrogate, by the municipal authorities, at a rental of £2 per annum. It is intended to use the land as a temporary rose trial ground. Adjacent to the pine woods and a little west of the reservoir, this land is peculiarly adapted for rose culture. The Hon. Secretary of the North of England Horticultural Society, who has done yeoman work on behalf of the Society in the north, is to be heartily congratulated on the fruition of this scheme, which has been under consideration for many months.

Rose Trials at Wisley.—The first meeting this season of the Judging Committee appointed by the R.H.S. to review and adjudicate upon the roses under test at Wisley, took place on Saturday June 27th, when thirty varieties, then in full bloom, were examined and pointed. The Committee's awards are based upon points given for hardiness, habit, foliage, freedom of blooming and its duration, colour, shape, fragrance and lasting properties. The first-class awards given last year by the Committee to Hawlmark Crimson, Betty Uprichard, Christine, Red Letter Day and Mrs. Wemyss Quin, were in all cases again confirmed by their inspection on this visit. Further meetings of the Committee have been arranged during the blooming season. The rose garden is situated about a mile from the main entrance to Wisley Gardens, and it is well worth a visit by all lovers of the rose, and, indeed, by everyone who has a genuine interest in a garden.

Trials at Wisley.—The Royal Horticultural Society will carry out trials of nerines and lachenalias in their gardens at Wisley during the coming winter. Raisers and growers are invited to send three bulbs of each of their varieties to The Director, R.H.S. Gardens, Wisley, Ripley, Surrey, so as to reach him by Friday, July 31st. He will be pleased to send the necessary entry forms on request. A trial of winter spinach will take place at Wisley during the coming winter. One packet of each variety should be sent, to reach The Director (from whom the necessary entry forms may be obtained), R.H.S. Gardens, Wisley, Ripley, Surrey, by Saturday, August 29th.

PUBLICATIONS RECEIVED.

"The Gardener's Calendar," a garden guide for every day of the year, by T. Geoffrey Henslow. (Published by Dean and Son, Limited, 29, King Street, Covent Garden, W.C.2., price 2s. 6d.) A practical little book which permits of notes recording work done day by day, and which will thus form a permanent record.

CATALOGUES RECEIVED.

Messrs. Sutton and Sons, Reading.—Seeds for Summer and Autumn Sowing.

Messrs. Cooper and Nephews, Limited; and Messrs. McDougall and Robertson, Limited.—A Spraying Guide for Insect and Fungus Pests.

Messrs. Austin and McAslan, Mitchell Street, Glasgow.—A List of Flower Show Fixtures for 1925. This list will be sent free to any of our readers who make application, and will be found most useful.

SIMPLE GARDENING

WEEDS, SEEDS AND SEEDLINGS.

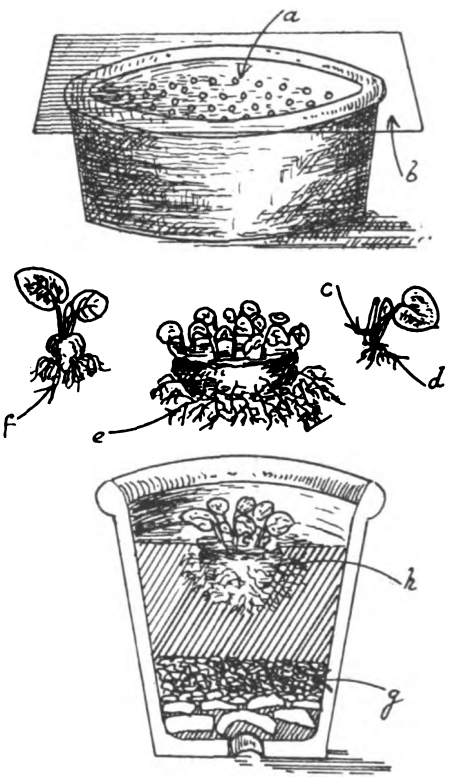
DURING the whole of the month of June it was possible to keep the garden free from weeds without much effort. I say it was possible, but, unfortunately, only a few owners of gardens took advantage of the long, dry spell of weather in this way, judging from the number of gardens I have lately inspected. The weeds in the borders, in the majority of cases, were small, but they seeded in this small state and laid the foundation for a fine crop of seedling weeds which will cause trouble very soon if the Dutch hoe is not freely used. Being small, the weeds in June were not noticed particularly, only in cases where the gardener is given to close observation. Not only does the free use of the hoe kill the young weeds wholesale, but a mulch is also created which breaks the surface crust and lets in air immediately and prevents undue evaporation of moisture from the lower soil. This conservation of moisture induces the roots of plants to penetrate deeper in search of it, which is much better than attempting to bring them to the surface by surface applications of water. In addition to the small, there are large weeds to be dealt with; these will be found in shrubberies, among bush and other fruit trees, in the rows of beans and peas, and even in the cabbage and cauliflower quarters. Hoeing is rarely beneficial in such places; hand-weeding is, if the offenders, when pulled up, are duly destroyed in the smother fire. If they are allowed to lie on the ground, many of them, especially groundsel, will mature seeds there.

LETTUCE AND ENDIVE FOR THE WINTER.

These two salad plants are of great value during a season when green salading plants are scarce. In the ordinary way both are easily grown, but at this season they need a little extra attention. If the weather is dry, the seeds for the autumn supply of both lettuce and endive should be sown in drills where the plants are to grow to usable size, and so avoid the work of transplanting and the check to growth. All plants which bleed freely at the roots when the latter are mutilated receive a serious check, and the result, in part, is apparent in the premature "bolting" to seed which, approximately, causes a loss of 15 per cent. in each batch so transplanted. Seeds of these plants are cheap and there are many of them in the smallest packet. It is well worth while spending a few pence more and having a larger packet so that seeds may be sown fairly thickly in the drills. The latter should be shallow and the seeds in them very lightly covered with fine soil. If the ground is almost dust-dry, pour water in the drills before the seeds are sown, but do not water after they are covered no matter how dry the soil may be. Germination will be rapid and sure, and at an early stage of growth the plants should be thinned out to about 8ins. apart in the case of lettuce and 10ins. in that of endive. For this autumn crop the soil should be rich, but for the crop that is to remain almost throughout the winter a soil of medium richness will be best.

CYCLAMENS.

These are ideal flowers for the amateur's greenhouse, and are economical plants to grow as they do not require much artificial heat during the winter months, and not any from spring to autumn. It is a good plan to make a sowing of seeds late in July or during the month of August where the means for artificial heating are limited, and in early September where unlimited heat is available. As these plants like cool conditions at this season, a cool place in a greenhouse or frame—the latter for preference—should be selected. Pans or pots are better than boxes for both seeds and



young plants. Light turfy loam, peat and leaf-soil, in equal parts, form a suitable compost, with a small proportion of rotted manure for the plants when the latter grow larger and near the final potting stage. Do not use manure for the seed pans. Thoroughly drain the pots or pans with clean potsherds; make the soil level, and dibble in the seeds singly 1in. apart, as shown at *a*, afterwards covering the pan with glass, *b*. Wait patiently for the seeds to germinate, as they are slow to do so. Keep the soil in an even state of moisture for seedlings and all plants after new growth begins. Old corms, now growing again, should not have any stalks, *c*, removed forcibly, as by doing this the new leaf and crown, *d*, may be pulled up; cut off such stems. Take care of the new roots of old, *e*, and young, *f*, when repotting. Pot corms as shown, providing sound drainage, *g*, and keep the crown of the corm, *h*, well up in the compost.

OUTDOOR OR BORDER CHRYSANTHEMUMS AND PLANTS FOR LIFTING.

The earliest varieties begin flowering in July, then a representative collection will provide flowers till November. The later ones receive more moisture and, moreover, flower during a cooler part of the year. For these reasons we should treat our earliest sorts more generously as regards liquid foods from the end of July to the middle of September, and so encourage a more robust growth. It is the general appearance of the plants now that should be our guide as to the amount of feeding advisable. If the stems are thin and hard, the lower leaves shrivelling and those about them turning yellow, then we should thoroughly saturate the soil with clear water and, in a few hours' time, apply weak doses of liquid manure liberally at least once a week. If this treatment be followed for one month, the result will be a fine batch of plants bearing masses of flowers. In some districts leaf-soil is plentiful, and if it is well rotted a surface mulch should be applied, as it will conserve moisture and have a neat appearance. Disbudding should be the rule where a restriction of the number of flowers on a plant will be an improvement; but disbudding should be very carefully done. Plants now growing in an open border, and which are to be lifted and transplanted under glass for flowering to form a succession to those in the borders should be neatly staked out to ensure firm, well ripened wood and leaves. Judicious watering and feeding must be the rule. These few details should be attended to now, as they are important; unripe wood will not bear nice flowers late under glass.

PREPARE NOW FOR THE AUTUMN GREENHOUSE DISPLAY.

Those who wish to be successful in maintaining a display of flowers in the greenhouse or conservatory throughout the year must look well ahead and make the necessary preparations. Most of the plants for the purpose we have in view now are, at the present time, growing in the open air or in cold frames. Berried solanums, Solanum capsicastrum and the scarlet-flowered salvias, coupled with the general favourites, zonal pelargoniums, are all in cool quarters outside, and should be cared for daily. Flower-stems should be removed before the blooms show colour, however eager one may be to see the different colours and shades. Certain shoots will grow longer than the majority; they must be stopped, and all plants should be so treated that the stems will be short-jointed and firm, then such will retain their normal condition in the duller days under glass. The zonals will not require much feeding, but the solanums and salvias should be liberally fed with weak and clear doses of liquid manure and soot water. The colour of the berries will be richer in consequence.

GEORGE GARNER.

SPRING-FLOWERING CROCUSES

BY H. A. GREATOREX.

WITHIN THE NEXT FEW WEEKS, BULB CATALOGUES WILL BE SCANNED AND VARIETIES SELECTED TO ADORN THE GARDEN NEXT SPRING. THE TINY BUT GRACEFUL CROCUSES CRAVE THEIR FULL SHARE OF ATTENTION AND A NUMBER OF THE SPECIES MENTIONED IN THIS ARTICLE SHOULD BE TRIED.

THE same kind of post-war confusion fell upon the winter and spring-flowering crocuses offered by the trade as afflicted those that flower in the autumn. There was the same disposition to confuse the identities of certain closely allied forms, the same inclination to send one common species —Tomasinianus, in this case—for almost anything that was ordered, the same evidence of mixed and impure stocks, and lastly, the same tendency towards improvement, till to-day, with quite a small number of exceptions, all the kinds offered may be trusted to be true to their respective names.

One of the first of the crocuses to brighten the short days of the New Year is Imperati. I have found this listed in three forms: the type, albus and Maw's No. 1. What the latter should be like I do not know. What I have actually received under this name is the Dutch monophyllous form. I have not seen it listed since 1920, nor have I received it since that year, though I have seen it from a Dutch source in a neighbouring garden. Not only does it fail to produce seed with me, but in five years it has formed scarcely any off-sets.

In 1920 this same Dutch form was sent to me when I ordered the type. But since that year an order for the type has always produced an interestingly varied assortment of the typical diphyllous forms—some plain, some lightly and some the heavily feathered, most with the exterior buff of a greyish drab tint, but a few with the buff of a richer yellow hue. The only white form I have so far got is the one in which the inner segments are faintly tinted with lilac, and the outer striped on a yellow buff ground to a slight but varying degree, with pale, rather muddy lilac.

Five other members of the Imperati group are listed. They call for small comment. Suaveolens does not seem to be obtainable yet. At any rate, what I always get for it is Tomasinianus. Corsicus, minimus and etruscus may be quite relied upon, though there is a richly feathered form of etruscus, supplied by Messrs. Barr under the varietal name superbus which is so extraordinarily like corsicus in appearance and so very unlike the plain forms sent under the type name, that one may well be excused for thinking that a mistake has been made. Apart from the difference in the corm tunics, I find the two species easily separated when in flower, by the fact that in etruscus, as I receive it, the throat is bearded, and in corsicus, glabrous. All the individuals of corsicus sent me by Messrs. Barr in three separate years have identical featherings. In minimus, on the other hand, it is difficult to find two alike. The two species are easily separated by their proper spathes, diphyllous in minimus, and monophyllous in corsicus. Minimus has the smaller and prettier flower. Finally versicolor in two forms, one with a lilac ground, is true enough.

ONE OF THE FIRST SPECIES TO RAISE ITS HEAD IN EARLY SPRING, C. IMPERATI.

C. SIEBERI DELICATELY TINTED BUT A ROBUST GROWER.

The spring-flowering members of the annulate group are represented in present-day lists by three species, biflorus, chrysanthus and ærius. Five years ago the only form of chrysanthus I succeeded in getting was the variety fusco-tinctus. Fusco-lineatus was also listed, but in place of it I received a small, dull form of speciosus. It has since dropped out of the lists. Fusco-tinctus is a pleasing crocus. Its flowers are small, but the bright golden yellow of its interior gains an added richness from the backing of the evenly stippled brown of the outsides of the outer segments, and contrasts brilliantly with the black of the anthers. Last year Messrs. Barr offered several varieties of chrysanthus, some white, some yellow. Their chrysanthus pallidus is not the form described by Mr. Bowles and figured by Moon in the second volume of "Flora and Sylva." It has a fine globular blossom, but is of a medium yellow colour with some obscure greyish featherings, and no sign of black barbs to its anthers. "Pallidu feathered" is very different. It has smaller flowers with more pointed segments, with a varying amount of brownish feathering on a pale sulphur ground, some paler than others, and some with and some without black barbs to the anthers. It is an exceedingly pretty crocus. A rather curious form is "Quaintness," yellow within and with the exterior evenly washed over with reddish brown, through which yellow brush marks show. Only two feathered white forms have reached me, Mr. Bowles' "Snow Bunting," a pretty flower with only slight featherings and black barbs to the anthers; and a chamlijah form which, although it lacks the black barbs, has its featherings, so like those of Mr. Bowles' seedling "Bullfinch," that there can be little doubt of its identity.

Digitized by Google

The large form of biflorus, known as the Scotch crocus, is quite true. The same can be said of the variety Weldenii, which embraces a number of forms from pure white ones to those which have the rich purple exterior of the Alexanderi type. Some are small and of a poor, ragged shape; but the best coloured specimens have fine large globose flowers. Biflorus Barrii, as I get it, is mixed. Most of the corms produce long, cylindrical buds, very heavily feathered. These flower very late—not until the Scotch crocus has finished—and are, I have little doubt, the real Barrii. With them are other corms producing much narrower leaves and short, ovate buds, with three lightly feathered stripes, flowering a little earlier. The same mixture comes to me as biflorus pusillus. Lastly, the beautiful ærius and its variety "celeste" are expensive, but quite true to name.

The rather bewildering group of little yellow crocuses related to aureus have been too much for British nurserymen. The earliest of them, vitellinus, is listed, but when I order it I get an unstriped form of graveolens. There is no doubt of this, the pale yellow of the exterior and the extraordinarily evil smell being unmistakable. Mr. Bowles tells me that Messrs. Van Tubergen have the true vitellinus. Graveolens itself is listed, and is true enough. Those which I receive are striped more or less with brown. It has pretty little starry flowers, and would be very desirable, if it were not for its dreadful smell.

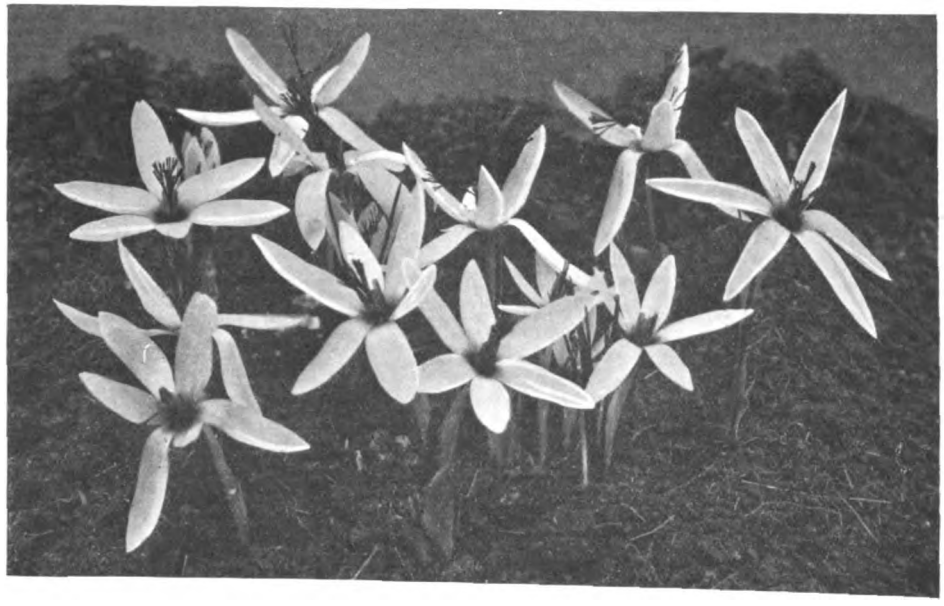
Two other small yellow crocuses listed are Olivieri and candidus subflavus. The latter is true to name. The former, however, as sent out by Messrs. Barr, has relatively such narrow leaves, and its throat and perianth tube so stained with purplish grey, that I long suspected it to be Suterianus, a suspicion which Mr. Bowles confirms. Aureus itself is quite true. It is of a most goregous shade of deep orange, almost pinkish orange in the bud, and grows very freely from self-sown seed. Of its derivatives two are listed, the Dutch yellow and aureus sulphureus. The latter is the concolor form. Four or five years ago I received under the name stellaris a crocus which at the time puzzled me very much. It had small, rather pale yellow flowers, decorated on the outside with three brown stripes. It is certainly not stellaris, and I have little doubt that it is one of the striped forms of aureus sulphureus. The only other member of the group listed, the very distinct looking Korolkowi, can generally be obtained, though occasionally Salzmannii erectophyllus is sent in its place.

Banaticus I have had from Holland. It is rather a poor doer. Besides the common garden forms of vernus a few small-flowered wild forms are offered, the prettiest of which is vernus "l'unique." Its blossoms are of an unusual shade of pale purplish pink, but it shows signs of dying out with me. Siculus from Mr. T. Smith of Newry, on the other hand, takes care of itself well but its small flowers are of a rather unexciting streaky purple. My slugs inform me that it has a better flavour than any other crocus in flower at the time.

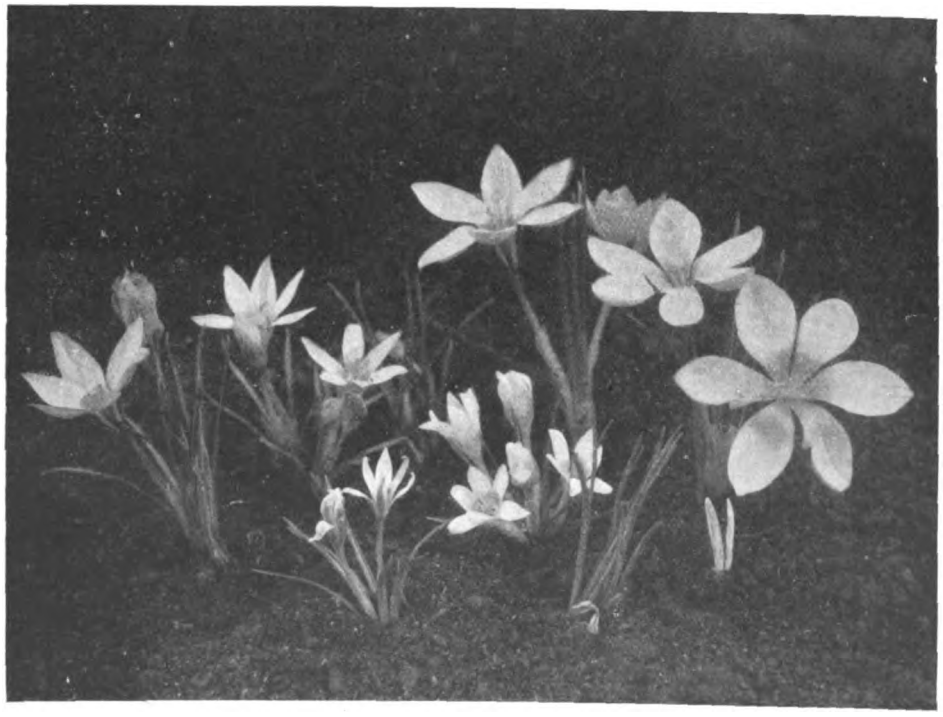
Tomasinianus in many shades of amethyst can be obtained without difficulty. It has a way of appearing when all sorts of other crocuses are ordered. A pretty white form reached me as longiflorus melitensis. Last year Messrs. Barr offered some of Mr. Bowles' beautiful variety pictus, and although late planting has made them rather pale and variable, I have not much doubt that they are true.

That delicately tinted, but robust grower, Sieberi, is obtainable only in the lilac Greek form. Susianus, with its rich mahogany exterior and distinct form presents no difficulties. It would be one of the best of all crocuses if it would flower more freely. Stellaris can now be obtained, though a few years ago Messrs. Barr sent out for it the really much more interesting striped aureus sulphureus mentioned above.

Finally, Fleischeri, with its remarkable corm tunic is quite unmistakable, and I have never found any disposition on the nurseryman's part to send anything in its place.



THE RATHER DAINTY AND UNMISTAKABLE C. FLEISCHERI.
This species is nearly always supplied true to name.



ONE OF THE MANY WHITE VARIETIES OF C. CHRYSANTHUS.

THE RAREST FLOWERS IN EUROPE

RARITY for its own sake appeals to the collector of postage stamps, but not to flower lovers, unless they be keepers of museums rather than of gardens. Yet there is something intriguing about a beautiful flower that hails from one place alone in all the world. Many plants are peculiar to one range only in the mountains; but I have in mind those that belong to a single hill or even rock. I imagine that even a schoolboy knows the wide-saucered blue or white bellflower that trails its beauty from many a hanging bowl in cool greenhouse or cottage window. From a few yards of rock, on which alone it grows in nature, on the small Cape of Noli that juts out into the Mediterranean not far from Genoa, Campanula isophylla has jumped into the homes of the people. Daphne rupestris, that shuns every limestone precipice on the Tombéa but one, and every mountain but Tombéa, bids fair to jump as far, when once the demand for its rose-pink stephanotis-like flowers and entrancing fragrance has compelled a supply at less than the guinea it now commands. Viola cornuta is as beautiful as common, in English gardens or on the Pyrenees; but its lone outpost across the breadth of France, where the high hillock of Grammont looks down on the Castle of Chillon across the Lake of Geneva, gives me the impulse to collect it just there, where it has been established by some strange freak. The most fragrant of the violets, the most unknown, Viola Comollia—of kinship with Dubyana and the other fine cenisias which are the unapproachable Ladies Vere de Vere of the mountains—is the rarest of the rare on only a scree or two of the Alps that stretch eastwards of Como, is as difficult to grow as to find, and as beautiful as it is unique with its light wine-rose petals endorsed with buff. One Corsican mountain alone stands sponsor for a dwarf columbine of the first water (yet who has seen it ?); and the cape that projects from the northern end of the island like a carbuncled nose, is the sole nursery of a sensational alyssum of normal gold and abnormal 3ft. stem. If this be a giant rarity, Thlaspi cepeæfolium is a pigmy one—the least in stature, the highest in quality of the iberis-like thlaspis, very different in habit from either of the two others that have found admittance to the alpine garden. This tiny treasure is almost entirely restricted to the low pass that cuts the Julian Alps in two near the new frontier of Italy and Jugo-Slavia, where the tourist struggles with names like Bohinska Bistritza, which he had never imagined outside of musical comedy. Not very far away there is a plant on which the limelight has been shed by no less than Baedeker, unrivalled guide but no botanist. Many a time and oft have I been unhappily lured by the words "rich flora" scattered throughout the fat little red books; and in one instance alone does Baedeker particularise as to what his rich flora might be: "Near Hermagor," he relates, "grows the Wulfenia carinthiaca, a beautiful plant with dark blue flowers, found nowhere in Europe except on the slopes of the Gartnerkofel"—and nowhere else nearer than the east of Asia.

E. ENEVER TODD.

SOME NORTH AMERICAN VIBURNUMS

BY E. H. WILSON.

MANY OF THE FINEST VIBURNUMS IN CULTIVATION ARE NATIVES OF NORTH AMERICA, AND AS YET THEY STILL AWAIT INTRODUCTION TO OUR GARDENS, WHERE ASIATIC AND EUROPEAN SPECIES ARE MORE COMMONLY GROWN.

AMONG the tree viburnums with deciduous leaves none is handsomer than V. prunifolium, the black haw. Native of eastern North America, it grows naturally on rocky hillsides and the borders of woods, and apparently delights in exposed situations. It is a small tree, occasionally 30ft., but usually from 15ft. to 20ft. tall, with a single trunk clothed with fissured bark and a shapely crown of straight, spreading branches clustered with numerous short, spur-like branchlets. These give a rugged character to the plant, whose habit resembles that of certain hawthorns. The leaves on red-purple petioles are oval, pointed or blunt, about 2ins. long and 1in. broad, smooth and dark green, and in the autumn turn a deep rich wine colour. The flowers are all fertile, pure white and are borne in flattened, rather small clusters which are abundantly produced about the end of May and early in June. Attractive in habit of growth and freedom of

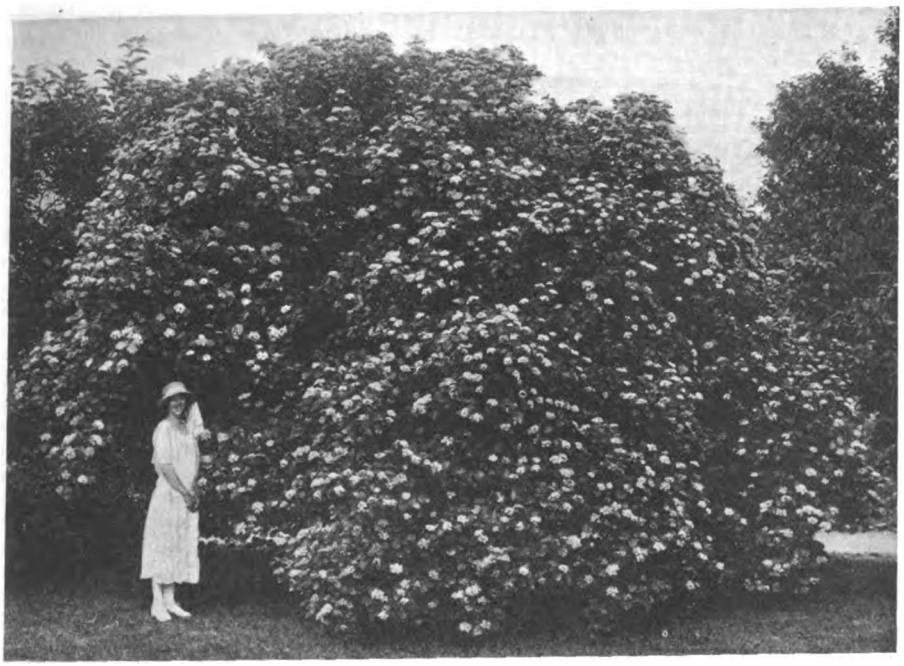
VIBURNUM CASSINOIDES WREATHED IN BLOSSOM. IT IS EXCEEDINGLY BEAUTIFUL WHEN IN FULL FRUIT.

Digitized by Google



THE ROUND-TOPPED V. CANBYI, THE LAST SPECIES TO OPEN ITS FLOWERS.

blossom, this viburnum is most beautiful when in fruit, which is borne in drooping clusters. It is relatively large, ovoid, changes as it ripens from green to pink and finally to dark blue, and nearly black at maturity when it is covered with a glaucous bloom.

In the Arnold Arboretum native shrubs either in groups or singly are freely used in the borders and by the roadsides. Since it is so very beautiful in fruit, V. cassinoides in several hundreds has been planted. The fruit as it ripens becomes first cream-coloured, then pink, and finally blue-black and bloomy. In the early autumn fruit of the three colours is present in the same clusters, and the effect is very lovely.

As we grow the viburnum it is a shapely shrub from 4ft. to 10ft. tall, with numerous ascending branches, but in a wild state it is often 20ft. high and of straggling habit. The leaves are variable in size, more or less oblong to broad-oblanceolate and pointed, thick in texture and shining dark green; the flowers are cream colour with prominent stamens, and are produced many together in broad convex clusters which terminate every shoot in mid-June. The fruit ripens in September, and is ovoid in shape and about one-third of an inch long.

This viburnum is a common plant in north-eastern North America, and seems equally happy in swamps or on dry rocky slopes. So useful a shrub ought to be better known in British gardens.

The last viburnum of the season to open its flowers is V. Canbyi. This is native of eastern North America, and blossoms about the end of June and early in July. Vigorous and densely branching, it forms a round-topped bush 10ft. to 15ft. high and broad, and is well suited for using as a specimen shrub or as a screen. The rich shining green leaves are roundish, prominently veined and coarsely toothed. The flower-clusters are flattened, round about 3-4ins. in diameter, and are densely crowded with pure white fertile flowers with prominent outthrust yellow-anthered stamens; the fruit is small, ovoid and dark blue in colour. In the autumn the foliage is tinted wine colour to rose violet.

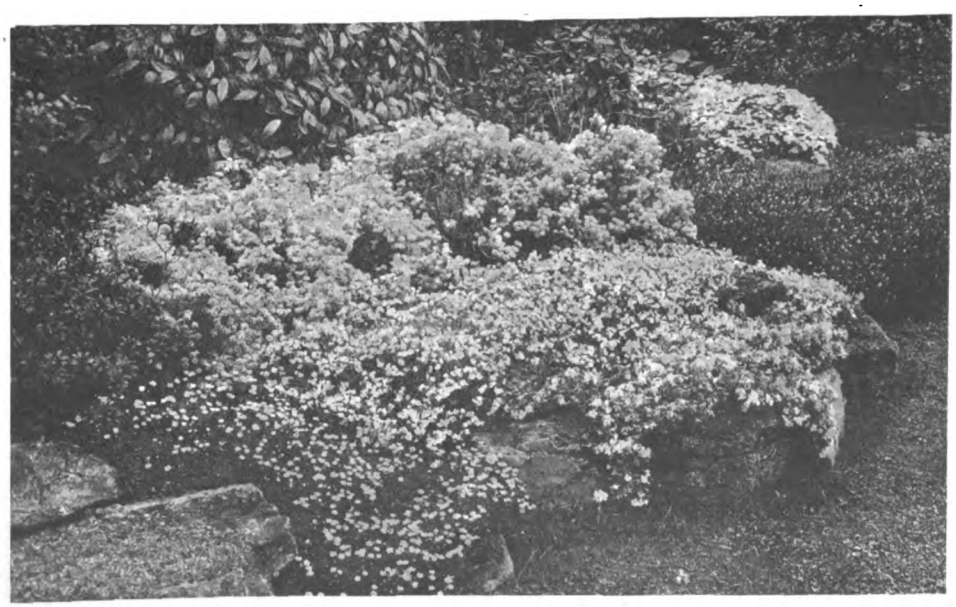
This viburnum grows naturally in moist woodlands, but in the Arnold Arboretum, where it has been freely planted, it grows well in any situation. Of rapid growth, it quickly makes a good bush, and is handsome either in flower, fruit or when decked in autumn foliage.

DWARF PHLOX FOR THE ALPINE GARDEN

NOW IS THE TIME TO MAKE PREPARATIONS FOR NEXT YEAR'S DISPLAY IN THE ROCK GARDEN. SPACE SHOULD BE FOUND FOR A FEW VARIETIES OF DWARF PHLOX TO ENSURE A TOUCH OF BRIGHT COLOUR AMONG THE OTHER ALPINES.

EVEN amid all the welter of gay colour that floods the slopes of the rock garden in May and June, the various "mossy" and dwarf phlox are capable of making their mark among the severest competition and forming cascades of brilliant flowers which "carry" far and wide. Not only is the colour range a wide one, but the species, too, are extensive and the variation in habit enables us to employ them in a variety of positions and thus gather up the fullest possible measure of their artistic possibilities. Upright growers, such as divaricata, with its erect stems 6ins. high and wonderful blue flowers, are simply glorious where used in large pockets either on a level with or below the eye. Another form of this, Laphamii, is very much larger, so far as the flowers are concerned, but the colour is not so clear.

A splendid form is the newer Violet Queen, whose colour is aptly described by the name. An exquisite little species of mat-like habit, with leaves so closely crowded together that they have a moss-like effect, is Douglasii; the tufts



SHEETS OF DAZZLING WHITE PRODUCED BY THE MASSING OF ALPINE PHLOXES IN THE ROCK GARDEN.

Digitized by Google

of green foliage are studded all over with lavender blue flowers which, when smelt, prove to be deliciously fragrant. Amœna, instead of clustering close to the earth, rises to a height of 6ins. and bears small heads of large deep rose flowers during the month of June. Ovata caroliniana is a specially neat grower, about 1ft. tall, that carries on its flowering season into August; the tufts of foliage are very close and terminate in heads of vivid rose pink flowers that are most effective.

The variety procumbens is especially valuable and interesting. To begin with, it is the effect of crossing P. pilosa and subulata, and has resulted in a very robust prostrate plant with masses of rosy mauve flowers that make a great display. The plant has the desirable quality of flowering again in autumn, a fact that suggests great possibilities by re-crossing backwards with the object of producing a similar desirable habit in the subulata varieties. Of pilosa, the most highly coloured form is Brilliant, a useful dwarf with intense rosy crimson flowers. Stolonifera deserves to be included if only for its early-flowering habit, though its claims are much greater than this; the plant is in the form of tufts of light green foliage surmounted by heads of intense rose flowers. Verna provides quite a contrast to this, for the leaves are in masses of deep olive green with—again—rose flowers. For sloping pockets where vivid colour is the important thing, both Stellaria (starry phlox) and subulata (mossy phlox) are extremely valuable, and a large number of varieties of each are available.

All the Stellarias are vigorous growers and rapidly make handsome patches. There is much confusion between these and the subulata section. All the following, however, are true Stellarias: Annulata, milky white with a purple ring; Bridesmaid, pale lilac with a deeper centre; G. F. Wilson, lavender blue, very free both in growth and flower; Newry Seedling, with starry mauve flowers; and Seraph, white with blue-eyed flowers.

The subulatas, with their mossy deep green foliage, are simply invaluable and should be lavishly used. These, by the way, look splendid when two or more varieties are planted side by side and run into one another in the course of their growth. Of these, atropurpurea, ruddy crimson; Brightness, rose with crimson eye; Frondosa, rose flowered with crimson eye; Fairy, rose with purple eye; Kathleen, lilac with crimson eye; Little Dot, pure white; Nelsoni, white with crimson eye.

Another use for the procumbent species is as a groundwork for beds of the May-flowering Darwin or cottage tulips. These flower simultaneously and, with the varied colour range of both tulip and phlox, remarkably beautiful effects can be planned. Propagation is very easily effected by means of cuttings taken immediately after flowering. These should be inserted in very sandy soil in cold frames and kept moist until well rooted, when they may be planted out at once in their permanent quarters. In selecting the position for planting in the rock garden, etc., the importance of abundance of sunlight should not be overlooked. A strong, rather stiff loam is the best, for in a light dry soil flowering soon comes to an end.

H. W. CANNING-WRIGHT.

COMPLETE CYCLAMEN CULTURE

WHEN MAKING UP YOUR BULB ORDER THIS AUTUMN THESE UNUSUAL AND GAY LITTLE GREENHOUSE PLANTS SHOULD NOT BE OVERLOOKED.

NOTHING could possibly be simpler than successful culture of the cyclamen, and certainly nothing could be more beautiful than the exquisitely coloured butterfly-like flowers, poised above the deep green rounded leaves that so gracefully clothe the surface of the soil in which the corms are growing. In common with many other flowers, remarkable improvements have been effected in recent years, and we cannot too strongly commend the purchase of a really good strain of seeds from which to raise the supply of plants.

Many varieties are named, and one gains the advantage by purchasing these in splendid colours which are true to type, for special care has to be taken, in this case, in the selection of the seed parents. Special attention may here be directed to the Sheepwell strain, which, in addition to giant size and splendid colourings, adds the further charm of a powerful and distinctive fragrance. Another interesting "break" that is worth noting is the silver-leaved strain. In this, the leaves are of giant proportions with a broad silver zone on a deep green ground, while the flowers are a bright salmon-rose. A few of the best of the named varieties are Giant White, Firefly, Giant Shell Pink, Vulcan, Queen Mary, Salmon Scarlet, Carter's White Swan, The Sultan, Crimson St. George, Scarlet King, Webb's New Scarlet Queen, Salmon Queen, Bath Beauty, and of the excellent "Caledonian" strain the varieties Lady Helen Cassel, Septimus F. Beck, and Giant White Wonder are beautiful both in shape and colour.

CYCLAMEN SALMON QUEEN WITH VARIEGATED FOLIAGE.

At the outset of this note, we expressed the opinion that culturally "nothing could be simpler," but the whole secret of this rests upon one point—you must keep them continuously growing, right from the day when the first leaf appears until the finality of flowering is reached. Never must there be a single day's pause or check or your plants will suffer.

Sowing may be done any time during August, September or even October, but an earlier date than the latter is to be preferred, as it gives a longer period of growth. Special care should be taken when crocking the pans in which the seeds are to be sown. The compost should consist of a mixture of fibrous loam, old manure from an exhausted hot-bed, and plenty of coarse silver sand. Press this down moderately firmly, and then water with a fine-rosed can, and all is ready for the operation of seed sowing. The best mode of doing this is by dibbling in each seed separately, at distances of an inch apart. It is sometimes recommended to cover the seeds, to a depth of half an inch, with soil; but we prefer the shallowest possible covering that will hide the seeds from view. To guard against their becoming too dry, cover the pan with a sheet of brown paper and place a pane of glass over that. A brisk warmth is necessary to germinate the seedlings quickly and

Digitized by Google

evenly and a minimum of 55° Fahr. is about correct. Directly germination takes place, remove the paper and glass and place the pan on a shelf so as to ensure the sturdiest possible growth—but take care that they are not scorched by sudden bursts of strong sunlight.

Pricking off need not be done until the leaves begin to touch each other, but care must be taken to keep the soil evenly moist. While a cool airy atmosphere is desirable for the promotion of the sturdiest growth, a strict watch must be kept that this never becomes too dry. Abundance of atmospheric moisture is the greatest aid in keeping them growing continuously, for once the outer casing of the corm becomes tough, which it quickly does in a dry atmosphere, good plants cannot result. By early February the little plants should have made sufficient progress for transfer to single pots, and a similar compost to that recommended for sowing can scarcely be beaten. The time for potting depends, of course, upon the progress made, the best time being when the seedlings are making their fifth leaf.

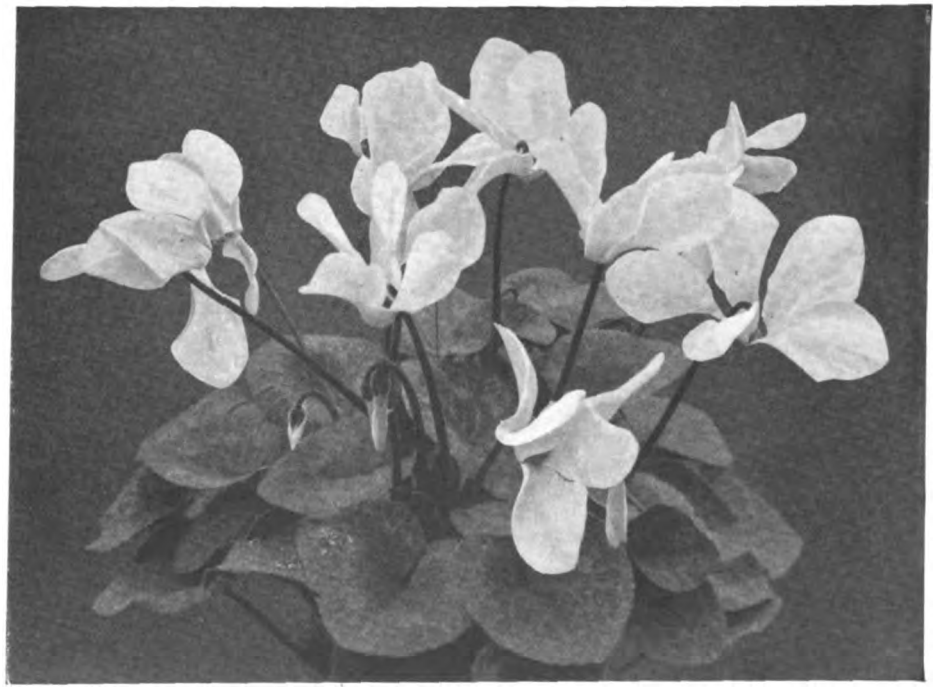
Observation will show that it is just about this time that strong roots begin to push out, and therefore they establish quickly under the new conditions. Especial care should be taken at this time to see that plenty of atmospheric moisture is present, and no better place can be found for standing the pots than on a staging covered with shingle or ashes that are constantly damped.

Potting must be done in the correct way, *i.e.*, so that the corm "sits" upon the top of a small mound of soil which slopes away on all sides to the rim of the pot. Lift the plants from the pans or boxes with plenty of soil adhering to the roots, drop them into the pots firm only by tapping the base of the pot on the bench. The cyclamen appreciates a loose soil, and there must be no pressing with the fingers or the soil will be too hard and roots will not run freely. Use tepid water for watering the soil, damp overhead twice daily, shade from bright bursts of sunshine and run the temperature up a few degrees, all of which aids in quick-rooting and re-establishment of the young plants.

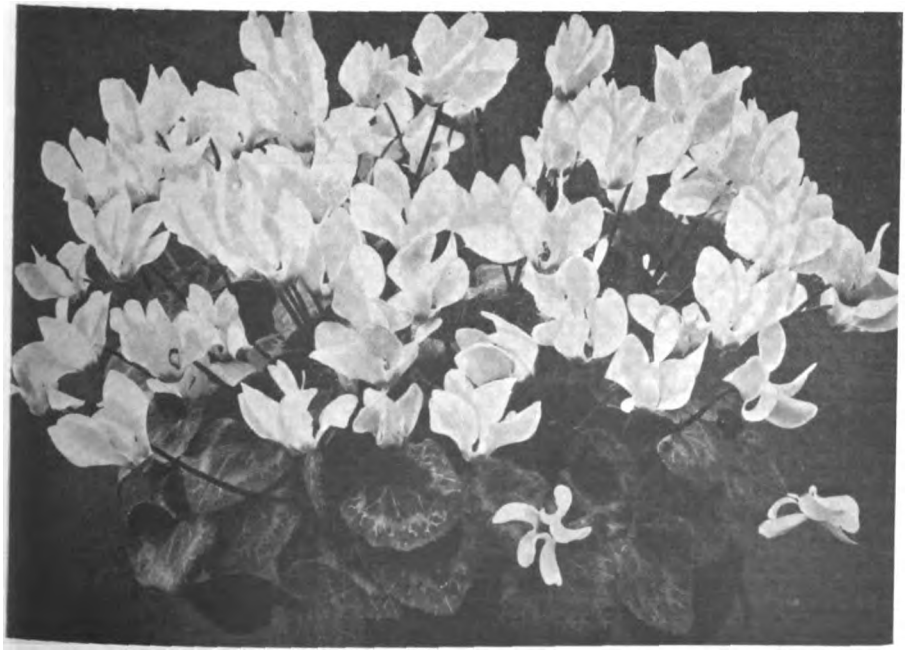
Through the late spring and summer, the chief needs will be regular watering and syringing and keeping the plants as cool as possible. After the lapse of about eight weeks, sufficient progress will have been made to permit of transfer to the flowering sized pots, which should be the 6in. or 7in. size, according to the vigour of the tubers. Follow the same methods as before, but use rather less sand and reduce the quantity of air admitted to the house for a short time until the roots get actively to work again. Through the summer, the plants do excellently when plunged in ashes in cold frames, and these, if facing north and judiciously ventilated, ensure the necessary coolness which is so essential to healthy growth.

By early October, plenty of buds will be forming and the plants should at once be placed in a good light position in an airy house, where, after a week, feeding with weak liquid manure may be commenced. Correct potting and care in watering will do much to prevent that troublesome decay that sometimes affects the corms. Take care to water early in the day and pour it on the side of the soil, so as not to flood the centre of the corm. All faded leaves and flowers that have to be removed must be pulled right out, not cut off so as to leave a bit of the base of the stalk still attached to the corm, or decay is certain to be set up.

Seed saving and cross pollinating is interesting work, and for this a few of the best plants should be set aside in a place by themselves. Cross pollination is readily effected by means of a camel-hair brush. Do this when the sun is bright, so as to ensure dry pollen, and take care that the seeds are fully developed before you pluck the capsules from the plant and also that the pod has thoroughly dried before you remove the seed from the capsule. Where such work is being carried out, a fair amount of attention should be devoted to the operation. The instruments, such as a brush and a pair of forceps, must be carefully sterilised each time, if it is intended to cross a few varieties at the one time, otherwise the results may be difficult of interpretation. After crossing has been accomplished, and seeds have been obtained, it is advisable to raise the resulting plants apart from the ordinary varieties, noting any peculiarities which may occur during their growth.



ONE OF THE FINEST VARIETIES OF THE PERSIAN CYCLAMEN, GIANT WHITE.



A FINE FLOWERED CYCLAMEN SEEDLING.

VEGETABLES AND THEIR DISEASES

BEET.

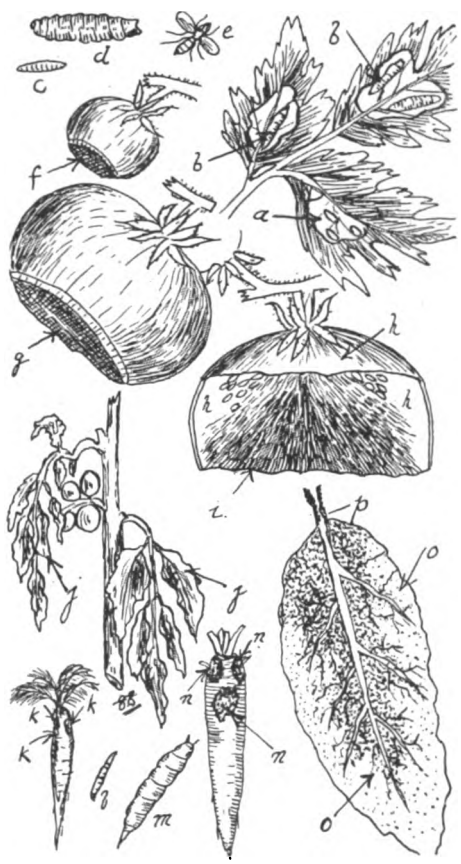
THIS excellent salad plant and winter vegetable attracts hordes of sparrows in every district where sparrows are encouraged to nest. They eat the leaves when the latter are about 3ins. high, and, unless stopped forthwith, cripple the young plants seriously. Nets, of fine enough mesh, are the surest protection, but I have found black cotton, two strands to each row, very effective, too. The cotton should be placed in position when the seedlings are tiny, being fastened to short sticks 3ins. above the tops of the plants. This, of course, is only a temporary trouble, as the sparrows do not eat the leaves of the plants from half to full growth; they do, unless stopped, eat the entire crop in a few days while the plants are young.

The beet rust is a far more serious matter. Last year some very fine even beds of beet were nearly denuded of their leaves by the middle of September. During the early stages the crops were very promising, but being grown in a heavy soil and the season coming wet and cold, too, the rust appeared at an early stage and soon destroyed all except the small, central leaves. The Bordeaux mixture is the only remedy that I know of, but I have found it advisable to sow beet seeds in two quarters, if available, in a light and heavy soil, respectively, then in a very dry season the plants in the heavier loam are the best, while those in the light ground escape a bad attack of rust and yield a satisfactory crop.

CELERY

The celery plant would be rather difficult to grow, even if it were quite free from disease and insect attack; but it is liable to be destroyed by one or the other, unless great pains be taken to combat the enemy. Last year many crops were not harvested, and half-rotted on the ground. The plants should have been destroyed at an earlier date, but the cultivators kept on hoping and as the sticks were below the soil, heaped up for blanching purposes, the extent of the damage was not fully observed. This damage to the plants was caused by the celery fly. In my own case I had a season's battle against the pest and as I wished to exhibit celery in strong competition, I was, of course, anxious. In spite of every effort, some leaves were attacked. Usually, cultivators do not begin defensive measures soon enough. The young plants suffer even before they are planted in their summer quarters. I have observed the fly at work in May and till the middle of June. At the end of July and throughout August, it becomes busy again. Although small, the fly can be seen on the wing clearly enough. The time to watch for it is towards sunset late in July and the middle of the afternoon about mid-June; look over the rows of plants towards the sun—or from east to west. They were like swarms of bees last summer.

The fly punctures the leaf and deposits [illegible]gs in the centre; when the larvæ hatch out they begin to feed on the juices of the leaves and soon create large blotches of tissue-like layers of leaf, which will, in due course, decay. The next stage is the pupæ, and from them new flies emerge from the soil about one month after the grubs are hatched in the leaves. The leaves should be made distasteful to the fly by syringing with an emulsion of paraffin oil and also quassia chips boiled and the liquid diluted well. Use these liquids weakly, but frequently—at least twice a week—and alternately. If grubs appear in the leaves, crush them between the thumb and finger. Scatter soot freely round the plants, together with a little salt to attack the pupæ and also to ward off the fly. Lime, I think, is useless. There is a tar remedy, but its application needs the care of an expert, and I do not recommend it to amateurs.



CELERY.—*a*, Leaf-mining grub as first seen in the leaf. *b*, *b*, Grubs slightly magnified, destroying leaf. *c*, Pupa. *d*, Maggot greatly magnified. *e*, The fly slightly magnified.

TOMATO.—*f*, Black spot first showing on young fruit. *g*, Disease developing as fruit swells. *h*, *h*, *h*, Sound portions of fruit. *i*, Shows section and disease quite spoiling fruit. *j*, *j*, Show sleeping disease; effect on leaves.

CARROT.—*k*, *k*. *k*, Young carrot first affected by; *l*, Maggot of carrot fly. *m*, Maggot greatly magnified. *n*, *n*, *n*, Shows effect of maggot attack on root as latter grows.

BEET.—*o*, *o*, Shows rust on underside of leaf. *p*, Leaf-stalk decaying.

The celery leaf rust is devastating during some wet seasons. I have seen plants freely treated with lime, but succumb rapidly. It is a fungoid disease and should be treated with the Bordeaux mixture. I believe some seed firms also treat the seeds as a preventive. Plant in a fresh quarter every year.

CARROTS.

Wireworms and even ordinary earthworms do much damage to carrots during the later stages of their growth, but the destruction of the roots by these pests is infinitesimal in comparison with that worked by the maggot of the carrot fly. Last autumn I visited a number of exhibitions and found four out of five dishes of carrots marred by the ravages of the fly. The early spring attack is the result of autumn egg production; then, till a little after midsummer, more broods are hatched. Although soil, in itself, especially that which contains iron, does have the effect of turning the leaves of carrots reddish-brown, the carrot fly does this, too. But, whereas, in the former case the leaves retain their upright position, they droop considerably when the grub attacks the roots.

To prevent attack, the following points should be observed. In the autumn decide upon the plot for carrots and dig in half a bushel of soot to the rod. In the spring prepare the soil, sow seeds and begin the work of thinning-out, while the seedlings are tiny, finishing the work, also, at an early stage. Apply water through a rosed watering-can immediately after each thinning, to settle the soil round those retained. Then lightly pass the Dutch hoe between the rows. Carrots like a light rooting medium and in such the maggots can work most easily.

The carrot fly is small, dark brown to black in colour, with lighter wings, which when they are shining, enable the fly to be detected. These insects can be seen with the celery fly on a warm, quiet evening. The crop must be made distasteful to the fly by syringing with quassia extract or petroleum emulsion directly, in a very fine spray, over the carrots, and by syringing paths, banks and any other vacant spaces near the bed, twice a week with a strong petroleum mixture. The oil may be mixed with sand in a pure state and so sprinkled on paths and around the beds. The fly will keep at a good distance away from the quarter where there is a strong smell of paraffin and sand helps to retain it.

TOMATOES.

White or snow fly is a pest that, in some years, has almost ruined huge houses of plants and caused much anxiety to the owners who depended, to a great extent, on the crops for their living. In the smallest house, however, the fly appears, and if not subdued, at least, will spoil the crop. I know one cultivator, who, some years ago, had to wash all the fruits before sending them to market. Now, happily, owing to various remedies, as advertised in THE GARDEN, the fly can be conquered. It is to such remedies that I advise

Digitized by Google

cultivators to look and not to depend upon washes that are home-made and often worse than useless. When, at the end of the season, the plants are cleared out, the whole of the surface soil should be watered with a strong emulsion of paraffin oil. At all seasons of the year keep down seedlings of the common buttercup, and beware of lettuce, cucumber and vegetable marrow plants, which also seem to attract the fly. But next to the tomato itself, I have found the schizanthus the most attractive. As the eggs hatch continually while there are live flies in the house, the remedies should be applied twice weekly till all are exterminated.

Tomato plants are subject to the potato disease (Phytophthora infestans), and the remedy in this case or the preventive, which should be the chief aim, is spraying with Bordeaux mixture.

Black Spot is caused by a too close, moist atmosphere, through lack of ventilation and undue crowding of the plants. The young fruits will set and swell normally, but the half-grown fruits are affected at the flower end, the skin or rind suddenly depresses, turns brown and then quite black. Such fruits should be gathered and burned forthwith, and, if there is undue crowding of the foliage, a few basal leaves should be shortened and extra ventilation given for a week or ten days. It seems to be a disease emanating from general mismanagement and not from soil mediums, though a constantly sodden state of the soil would aggravate matters.

Sleeping Disease (Fusarium lycopersici). so called because the appearance of the affected leaves suggests sleep; they droop as if suffering from lack of moisture at the roots. The trouble begins in the soil, first affecting the roots, then the stem, destroying tissue and sap vessels. Usually, on its first appearance, odd plants only are affected, but if precautions are not taken, whole crops succumb in following years. Every year fresh soil should be used, and with it old mortar rubble or a free sprinkling of dry lime, wood ashes and, later, soot. Of course, any diseased plants found should be burned forthwith.

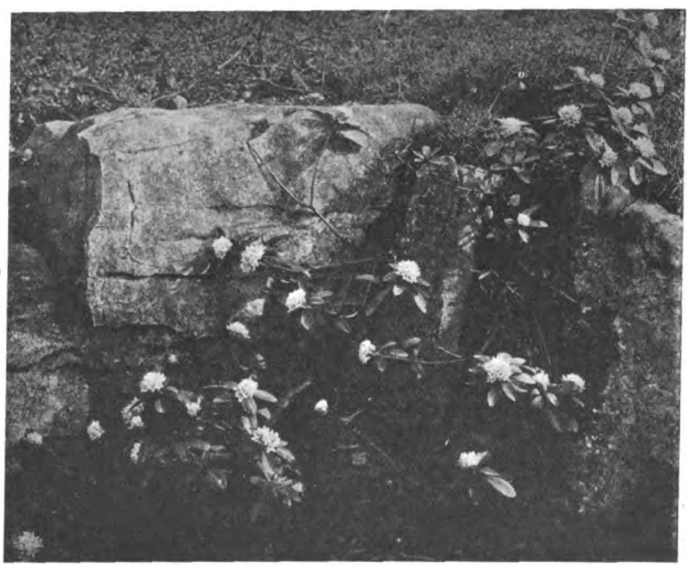
Leaf Rust is common and present with us, more or less, every year. It can be prevented by judicious planting, watering and ventilation. The brown, pepper-like patches under the leaves are due to a fungus growth, which a close, moist atmosphere favours, especially when the roots are in a wet soil—one too close and moisture-holding. The way to prevent the disease, then, is obvious, and its remedy when first observed is an application of Bordeaux mixture. It is beneficial, on hot days, when these alternate with dull, damp ones, to disperse flowers of sulphur gently among the plants. If an instrument for this purpose is wanting, take a small square of glass, place a pinch of sulphur on it, hold well above the plants and then suddenly blow it off the glass. Use more sulphur and repeat till all the house space has been so treated. This is an excellent method of counteracting this disease. G.

NOTES FROM CONTRIBUTORS

DAPHNE BLAGAYANA.

THE genus daphne contains several interesting and useful members, suitable for the rock garden, and no doubt everyone desires to possess as fine a specimen as possible of the plant illustrated. The photograph was taken at Castleford, Chepstow, the residence of Mr. W. R. Lysaght, where D. Blagayana succeeds fairly well, and D. Cneorum is represented by several large clumps.

The plant is growing between two rocks, in a mixture of peat and leaf-mould, and the position is slightly shaded from strong sun-light. The flowers are creamy-white, fragrant and usually appear in March and April. It is a dwarf evergreen shrub, with a spreading habit, and it appears to require pegging down directly any shoots are long enough for that purpose. Roots are eventually formed, and so the plant renews its energy, a condition which is essential to keep it healthy. A few small stones placed in the soil is an advantage, and during a spell of dry weather (which occasionally happens just as the plants are completing their season's growth), the roots are soaked with rain-water. We have rooted it from cuttings, these being taken in August and placed in a cold frame. During the autumn and winter a callus was formed, and when potted off in the spring and placed in a cool greenhouse, a large percentage made roots. D. Blagayana is a native of the mountains of eastern Europe, being discovered by Count Blagay in 1837, and introduced about 1875.—T. W. B.



AN EXCELLENT ROCK GARDEN SHRUB, DAPHNE BLAGAYANA.

FREESIAS—NOTES ON CULTURE.

A TIMELY reminder may be of service to those who like to have a few potfuls of the coloured varieties; for there is no doubt they require rather more care than one used to give the old white ones. They seem to be very susceptible to cold and it is essential that both the soil in which they are potted should be warm and not sodden by rain or wet, and that the pots should be put under cover at once and very carefully watered. I go so far as to put a little heat in the pipes for a few days, should the weather be cold and damp. The start is everything with the coloured varieties. If they catch a "couth" (as we say locally), it would appear that all wish to appear above ground is suspended for a year. Not that there is nothing doing in the corm itself. It is busy enough down below forming a new one on the top of the old in a similar manner to gladioli and crocuses. Another point to remember is that the coloured varieties are not so easy to force as the old whites. It may be that growers will find out that all varieties are not the same in this respect, *e.g.*, among my yellows there is a considerable difference. Cowslip comes in nearly a couple of weeks before Flame when grown side by side under identically the same conditions. The cultural directions printed in catalogues do not differentiate between the requirements of the white and the coloured. On turning out my corms this summer I have been greatly struck with the difference between those grown in light soil in which there is plenty of leaf-mould and that containing less. I think the leaf-mould helps to conserve moisture, which is all important.—JOSEPH JACOB.

FAILURE OF GYPSOPHILA

A FEW weeks ago one noticed how, in many quarters, clumps of Gypsophila paniculata, established some years, and which, up to within a few days of the buds appearing, were full of promise, suddenly fail and die off. To those who have not met with a like experience, these collapses are somewhat inexplicable. Naturally, one would imagine—if the weather be at all dry—that it is lack of water at the roots, or that they are attacked with some insect pest. In nine cases out of ten it is neither one nor the other, but is due to one simple cause: a deficiency of lime in the soil. Usually these failures are met with in places where it is known that lime does not enter into the constituents of the soil, and sooner or later, the inevitable must happen. It appears strange to those who grow the perennial forms of gypsophila that the breakdown mostly occurs when plants are about to flower, but it is easy to understand that these lime lovers, missing the very element so necessary to their existence, should fail. The only remedy is to supply the deficiency, and a good dressing of superphosphate or mortar rubble, whilst it will not revive the drooping shoots, will at least do much to prevent further failures. It is essential that old plants in soil where little or no lime is found, should have forked in about the roots, lime in some form. This, I find, is best done in spring.—W. LINDERS LEA.

TORCH LILIES.

THROUGHOUT our countryside there are certain familiar wildings that, in their flowering season, add bold colours to the landscape. Such are the kingcups that

Digitized by Google

set the marshes aflame; and the gorse upon the common, when touched with flowers at every point, shines like burnished gold; or a breadth of red poppies in a field of corn under the noonday sun. So, too, there are flowers in our gardens that, in the zenith of their beauty, strike a distinctive note. Among them are kniphofias, or tritomas, known also under other designations as flame-flowers, red-hot pokers and, what to me seems most appropriate, torch lilies. One recognises that when they commence to bloom—though some do so a little earlier than others—autumn days are close at hand, and the opening of their fiery spikes is contemporary with misty mornings that bring a cold nip in the air.

Torch lilies indicate that the final stage of garden beauty is near, and they light the way with glowing colour. We know them as hardy plants that, once established, do not call for much interference; indeed, the less they are disturbed the better. But are they quite as hardy as we assume, and have not many been surprised after a winter when snow has lain long on the ground to find, when examining them in spring, that decay has set in? Years ago I had an experience of this sort, and afterwards took the precaution to tie up the reed-like growths to a stout stake, which kept snow and a deal of wet from the crowns, until the time came when the old material could be cut away.

In thinking of these stately flowering plants, many are apt to conjure up in their minds the crimson and orange-scarlet spikes as represented by Nelsoni, aloides grandiflora, nobilis and corallina, and do not always take into account the softer colours to be found in Goldelse (yellow), Lachesis (deep yellow), Lemon Queen and Aurora (coral). These old-time plants are best seen in a garden, where their tall spikes can be admired, with an intervening space of lawn, or on the fringe of a border, having as a fitting setting to their beauty a background of pine or other bold foliage.—CLAREMONT.

MESEMBRYANTHEMUM AS A CLIFF PROTECTOR.

HOLIDAY-MAKERS are often interested in the extent to which mesembryanthemum, particularly M. edule, is being employed for the protection of British cliffs. It is strange to think that this South African succulent is playing quite an important part in checking coast erosion. It has been proved that the plant will flourish on cliff faces, where it hangs down like a giant carpet and entirely checks further falls. Strong winds, salt spray and a sun-baked soil do not have the least harmful effect on the mesembryanthemum, which, in very unfavourable positions, will grow with a vigour that can hardly be surpassed in the vegetable world. A small shoot of the plant about the length of a finger will, in a summer, cover an area of ground 6ft. square. Whether the surface is level or nearly vertical does not seem to make the least difference, for the mesembryanthemum goes ahead binding the soil so that it will never move again. Often the succulent grows down to within a few feet of high water mark, and in the winter it must be soaked with salt water. Mesembryanthemum is not really very hardy, but on most of the English coast line, and also the western side of Scotland, it goes through the winter well. That the plant will stand a certain amount of frost is clear, for the present writer has noticed that specimens were unharmed when the thermometer fell 6° below freezing point.—L. B.

PRESERVING DELPHINIUMS.

AN interesting way of preserving the spikes of delphiniums is on the following lines: Cut the spikes with a liberal amount of stalk when they are just at their best. Now place them in a vase in which there is not more than about 2ins. of water. The delphiniums should be kept in rather a cool room, and it is most important that they should not be in direct sunshine. No more water should be added, but before that in the vase disappears a good number of additional flowers will have expanded. Leave the spikes until they become completely dry, by which time they will have been perfectly preserved. The flowers not only retain their shape, but, in addition, lose very little of their colour. The colour is retained as long as the spikes are not placed in the sun, in which case they quickly fade and turn to a dirty grey shade. Delphiniums seem to be the only flowers that can be preserved in this manner, as attempts with other herbaceous perennials were complete failures. —S. L. BASTIN.

EARLY CABBAGE VARIETIES.

ELLAM'S Early Spring is a fine dwarf, compact cabbage, and the first from which we cut this year, being ten days earlier than any of the other kinds grown here. All the varieties were grown on the same border and the plants set out early in September of last year. Flower of Spring, Ellam's Early Spring and Harbinger are in general appearance about the same, *e.g.*, height, colour and leafage, and to a certain extent the same in formation of growth and quality of earliness, yet if carefully examined points of difference may be noted, such as the outer leaves of Flower of Spring being of a lighter shade than the leaves of Ellam's Early Spring. Early York is quite a distinct type of cabbage from any of the others. The plants are big and of a loose-growing nature, while the leaves are of a blue-green colour. This variety has nothing, so far as I can see, to recommend it as a first early cabbage, as even now, in the middle of May, some of the plants have only commenced to form hearts. It should interest all who grow cabbage to know that the late Mr. Charles McIntosh mentions in his book, "The Practical Gardener," published eighty-six years ago, Early Dwarf York and Large York cabbage, two varieties still catalogued by present-day seedsmen. They have stood the trying test of time and are still to be had. —DAVID ARMSTRONG, *Midlothian.*

THE YELLOW SWEET PEA.

THERE is probably no horticultural novelty so eagerly anticipated or so strenuously worked for by everyone connected with plant improvement as the yellow sweet pea, and yet it seems as far away as ever. There are no doubt intense creams on the market entitled to be classified as pale yellow, but certainly there is no variety in existence having flowers of a decided buttercup yellow, the colour which haunts the dreams of the sweet pea hybridist.

A new variety may arise in one of two ways. The first is seen when, as the result of a cross, man-made or natural, existing characters are reassorted and a new combination formed. By far the larger number of the new types arise in this way. The second class of origination occurs when the plant for some reason "sports" or mutates to throw an entirely new "break." The first method is the only one available to the hybridist. He can only juggle with and recombine the characters provided by Nature. Mutation or sporting, the second path along which improvement may pass, is a peculiarity of the plant, and there is no method known for producing it. A new break of this type, however, nearly always leads to many new varieties, as the new character is worked into the existing forms by crossing. An outstanding example of this was seen when the advent and subsequent exploitation of the Spencer type duplicated practically every variety then in existence. The peculiarly interesting point about the yellow sweet pea, however, is the uncertainty regarding the way in which it may arise. As is generally known, yellow flower colour, if it is to have any "substance," must be based on little solid bodies (plastids) floating free in the cell, while all the other colours are the result of fluid dyes or cell sap. Both the solid and the liquid forms of yellow are available in the sweet pea, but as yet they have not occurred either singly or together with sufficient intensity as to produce "buttercup yellow." Now, running through the plant breeder's mind is the question whether it is possible to combine the yellow cell-sap or the yellow plastids in one plant with the known factors for flower colour intensification, so that an intensified shade of yellow may be produced, or are the intense creams at present on the market the result of this meeting and therefore the farthest we may go by means of crossing? If this latter be the true state of affairs, then horticulture can only wait until Nature provides what is not already there. With our knowledge of the sweet pea in its present state it is hard to tell if all the necessary conditions for producing the yellow have ever been satisfied, and therefore hybridists will be well advised to continue their labours and growers to continue their search. While inter specific and even inter generic crosses have always been mooted as a means of bringing yellow to the sweet pea, they can hardly be encouraged, because sterility, that spectre which haunts the too enterprising hybridist, nearly always steps in at some stage of the work. The most likely line of work seems to be inter-varietal crosses using always as one parent a variety known to carry the yellow tinge, as, for example, some of the scarlets and orange types.—ALEXANDER NELSON.

RUBUS ALCEÆFOLIUS.

A GOOD many brambles from the East have found a place as ornamental shrubs in our gardens. Most of them are perfectly hardy, but a few can only be grown under glass. Rubus alceæfolius is one of these. It is a fine huge climber, well adapted to be grown against pillars or similar places in a temperate house, where it will form a very attractive specimen within a short time. It has stout tomentose prickly stems and most beautiful, large, 5–7 lobed and lobately dentate leaves of a pleasant bright green on the slightly pubescent upper side. The back of the leaves is densely white or yellowish tomentose, especially on the younger ones, which adds greatly to their beauty. The flowers are rather large, white, and stand in short-stalked clusters in the axils of the leaves or in a terminal panicle at the top of the branches. The calyces are densely hirsute from rather long and stiff yellowish hairs, and bracts and stipules are finely split into numerous very narrow segments.

The plant succeeds well in a substantial fresh soil and in a place not too much exposed to burning sunlight. It grows and flowers freely for most of the summer until late in the fall.

R. alceæfolius is a native of Java and Sumatra, where it grows in forests and among bushes up to a considerable altitude. It would well deserve to be tried out of doors in gardens of a milder climate, such as in south-western Ireland, in the Scilly Isles and along the Mediterranean. But it should be planted in a sheltered place, where dry and cold winds, or excessive sunlight cannot hurt it. Wherever it will grow successfully it will form a valuable addition to the shrubbery, both from the point of view of blossom and foliage.—ALWIN BERGER, *N.Y. State Agricultural Experiment Station, Geneva, N.Y.*

CORRESPONDENCE

SAXIFRAGA COTYLEDON CATERHAMENSIS.

SIR,—I have been noting the beautiful saxifrage under the above name at Chelsea, and have no doubt it is a hybrid between S. Cotyledon and S. Hostii or S. Macnabiana, which is itself a hybrid. Some years ago I grew a form under the name of S. Cotyledon which proved to be one of these hybrids. In this form, however, there was a much greater length of stem before flowering branches were reached, showing the leggy character of S. Hostii. The true S. Cotyledon has pure white flowers, with very narrow petals, four times the length of the calyx lobes. The flowering branches commence a little above the base of the stem, and continue to the apex, each branch carrying five to fifteen flowers. This form was much grown in the early eighties of last century. Single crowns were potted up in small pots, and shifted when necessary till the crown of leaves would cover a 5in. or 6in. pot. When the plants commenced to flower they were taken from the cold frames to the greenhouse or conservatory, where the stem reached 30ins. or more, and formed a perfect pyramid of flowers. The new form S. C. caterhamensis is more conspicuous by reason of the broad, handsomely spotted petals. Insects readily hybridise these saxifrages when brought together in gardens, independently of artificial crossing, while hybrids are frequent in the wild state.—KEW.

PRIMULA HELODOXA.

SIR,—Primula helodoxa is now in splendid bloom here, and greatly admired by all who see it. A kind English lady sent it last year and I followed her directions as to treatment, and if I can get seed from its four fine trusses, I shall feel well pleased. Should this short account of it meet her eye, I would be grateful if she would kindly write to me anent its propagation. I live in fear that after its seeding time it may die. The very showery and cold spring evidently suited it very well. Now we have tropical heat.—L. HILL POE, *Riverston, Nenagh.*

VIOLA HETEROPHYLLA.

SIR,—Two summers ago, I collected from the Cima Tombea a few plants of Viola heterophylla—a dainty little pansy in the cousinship of V. cenisia, and belonging to a section rather notorious for difficulty. My collected plants did not live more than a year; but they died all of them carrying fat capsules of seed. This seed, which was sown in autumn, in a spirit of no great optimism, germinated in two or three months, almost as readily as a pink, and left me with several nice little plants, which grew rapidly and compactly, flowering, some of them, the next year. The plant in nature was of a rambling character, with long underground roots cropping up here and there into a clump of foliage and flower; but the seedlings have not got this rambling habit, but grow into neat, compact plants. Moreover, the plants have been perfectly easy to grow, and are, at any rate in the limestone moraine in which they are planted, very free flowering. Lastly, and most important, they are definitely beautiful—a little angular pansy face of purple, with a distinct patch of darker purple round the centre and little eye-lashes of black—small, indeed, but large for the size of the plant. Is it possible that here, as in the case of many a difficult alpine, the solution of the cultural problem is to raise plants from seed, thus getting more initial vigour than can be possible with a collected piece, however carefully re-established? Could anybody give me news of seedlings raised from the three other high-alpine pansies, V. cenisia, valderia and nummulariæfolia, which I have never met in nature or in cultivation? If raising seedlings is the best way of cultivating all these four high alpines, it may well be that we might make easy friends with four charming pansies, which have hitherto been dismissed from the mind—and from the garden—as paralysingly difficult.—R. L. HOLDSWORTH, *Harrow-on-the-Hill.*

TRILLIUM GRANDIFLORUM.

SIR,—There was some correspondence in your columns of late concerning rabbit-proof plants, and although I have learnt by experience to be chary of pronouncing *any* plant to be safe from these all but omnivorous rodents, I venture to recommend Trillium grandiflorum as practically immune from attack. Of course, when newly planted, rabbits will bite it off out of sheer cussedness; but if the plants are protected when first set out in the woods until they are well established, they are left unhurt afterwards. That is our experience here, and trillium looks far more charming in woodland than in a flower border. I wish I could send a photograph of this plant in the wild. Failing that, I enclose one of a patch in the flower garden which has been established for more than thirty years and never fails to bloom profusely.—HERBERT MAXWELL, *Monreith.*

A FINE PATCH OF TRILLIUM GRANDIFLORUM IN A FLOWER GARDEN.

THE MINIATURE DAFFODILS.

SIR,—Allow me to add a little information to the recent notes on some of the smaller narcissi by your correspondents Mr. E. Cahen and Mr. J. H. Watson, as my experience goes farther back than theirs. N. triandrus calathinus was first introduced by that distinguished scholar, botanist and gardener, my old friend the late Charles Wolley Dod. In 1884 or 1885 he obtained bulbs from the Botanic Gardens at Brest, some of which he gave to me, and I have perpetuated the plant from seed ever since. It was his custom, when visiting a relative near the foot of the French Pyrénées, to employ a collector of narcissi from the lower and higher levels. It was from him that I had the little N. moschatus, now, I fear, almost exterminated from its habitat in the Gavarnie district. The discovery of N. pallidus præcox was due to him, also of other wild narcissi now lost to cultivation. He was acquainted with the ordinary form of N. triandrus long before it was "found" by Mr. Peter Barr. Before 1890 I had gathered together, mostly from Mr. Wolley Dod, a considerable collection of these small forms, and raised a variety of interesting hybrids between them, using also forms of N. corbularia. The late Sir Michael Foster produced some hybrids identical with mine. But they proved difficult to keep; some may still exist with friends to whom I gave them as rockery or alpine-house plants, but I have long since lost sight of them and of most of Mr. Wolley Dod's gifts.—G. H. ENGLEHEART, *Dinton, Salisbury.*

CLERODENDRON UGANDENSE.

SIR,—Can any of your readers give me any information about this plant? I have seen it at the R.H.S. and also at Kew, but do not know if it has been tried out-of-doors in Cornwall or Ireland yet: it has bright blue flowers, and I thought it most attractive.—H. G. HAWKER, *Devon.*

GARDENS OF HEALING.

SIR,—The articles on "Gardens of Healing" in THE GARDEN were very interesting indeed. I wonder if some of our old country remedies would interest readers. In the following recipes "tea" means 1 oz. of the dry material brewed with 1 pint of boiling water and allowed to stand an hour. Speedwell.—Tea for gout. Yarrow.—Tea for colds, to be drunk warm. One cupful for a dose. Meadowsweet.—For children's diarrhœa, 1 oz. of leaves to 1 pint of boiling water. One wineglassful for a dose. Plantain.—Tea for diarrhœa. Leaves for stings and bites and a poultice for wounds. Ragwort.—Tea of leaves for sciatica, rheumatism and influenza. One wineglassful per dose. Woodruff.—Tea for liver complaints. Dried and stored will keep away moths. Balm.—Tea, 1 oz. of young tops to 1 pint of boiling water. Stand a quarter of an hour. Drink freely for feverish patients. Rosemary.—Tips of leaves and flowers infused and strained. Add a little borax. This prevents baldness. Camomile or poppy heads dried and used in boiling water will ease faceache if inhaled. Virgin lily.—Petals stored in wide bottle and covered with brandy will heal cuts. They will keep for years. Coltsfoot.—A handful of leaves to 1 quart of boiling water. Stand for twelve hours. Sweeten and give one cupful for coughs. Ground ivy for weak eyes. Leaves and flowers infused with boiling water. Bathe two or three times a day when cold. Watercress for eczema. Wash well, melt lard and stir in watercress until bright green. Goosegrass and nettle tea for purifying blood. Plantain, ground ivy, vervain and bean flowers in equal quantities make a healing lotion. Cowslips as tea for nerves. Violet leaves (garden)

Digitized by Google

alleviate pain and cure cancer. Greater celandine, chelidonium or swallow-wort makes "golden ointment." Squeeze juice out of stalk, add one tablespoonful to ¼lb. of lard. Mix well. Vaseline for wounds and bruises. House leek for corns. Peel skin off leaf, bruise it and bind it on the corn with a strip of linen. Repeat two or three times. Mugwort seeds mixed with tobacco, 1 oz. of tobacco to ¼ oz. of mugwort, relieves asthma. Lime blossom for a tessicking cough. Dry and brew like tea.—H. LAMBERT.

SAXIFRAGA OR MEGASEA LIGULATA

SIR,—The illustration of the Siberian saxifrage shown in THE GARDEN of July 4th is, I see, named Saxifraga or Megasea *crassifolia*. Unless the Kew authorities have lately refused to consider the many varieties of this saxifrage as worthy of distinct names, I beg to state the excellent plant shown there is *not* crassifolia—for that species has big, cabbage-like, circular foliage and short stumpy spikes of dull pink flower which appear much later in the season. As far as I know it, the name generally given to it is ligulata, and it is far superior to the crassifolia form, which was that commonly grown in England until folk brought this from the south of France.—E. H. W.

GARDENING OF THE MONTH

FLOWER GARDEN.

AMARYLLIS.—Plant now in holes 6ins. deep.

ANNUALS.—Sow now on warm dry border, eschscholtzia, Shirley poppies, clarkia, candytuft, cornflowers, nigella, phacelia, etc.

ANTIRRHINUMS.—Sow now thinly. Prick out into well drained border or into frames.

BULBS.—Commence planting and preparing sites. Plant daffodils in grass and bulbs in the wild garden. Plant now bulbocodiums, crocuses, colchicums, leucojums, Scilla sibirica,

CARNATIONS.—Finish layering.

CHRYSANTHEMUMS.—Disbud and tie up. Give artificials once a week.

LAVENDER.—Insert cuttings in sandy soil, and water. Cut flower spikes soon.

LILIUM CANDIDUM.—Plant now in clumps. Place sand at base of bulbs.

PRIMROSES AND AQUILEGIAS.—Transplant to permanent quarters.

PROPAGATION.—Take cuttings of hydrangeas, salvias, ageratum, pentstemon. Insert in sandy soil in frames. Water and shade.

ROCK PLANTS.—Propagate by cuttings saxifrages, sempervivums, sedums, etc.

ROSES.—Feed hybrid perpetuals with liquid manure. Insert cuttings of ramblers in sandy soil. Remove faded flower shoots of climbers. Prune ramblers after flowering, and tie in young shoots. Bud more roses.

SEEDLINGS.—Plant out foxgloves, bellis-perennis, pansies, sweet william, Canterbury bells, etc.

SHRUBS.—Clip yew hedges. Remove dead flowers. Hoe and weed shrubberies. Examine grafted trees, loosen ties. Propagate by cuttings such shrubs as philadelphus, cistuses, helianthums, deutzias, rhus, tamarisk, etc. Insert half-ripened shoots in sandy soil, cover with a hand-light, or, if available, place in propagating case with slight bottom heat.

STOCKS.—Plant out Brompton stocks into sheltered spot.

SUMMER BEDDING.—Remove fading leaves and flowers. Keep tall plants well staked and carpet plants pegged down. Propagate by cuttings zonal pelargoniums, ivy-leaved geraniums, fuchsias, violas, pansies, ageratum, verbena, heliotrope, etc.

GENERAL.—Weed lawns. Apply weed-killer to paths.

HARDY FRUIT.

BUSH FRUIT.—Thin out excessive growths. Prune black currants, burn trees badly infected with big bud. Spray gooseberries infected by American gooseberry mildew.

CHERRIES.—Thin Morellos for culinary use. Net trees well. Train in young shoots. Give good supplies of water.

FIGS.—Feed regularly trees carrying good crops. Remove coarse growths and train in young shoots. Expose fruits to sun.

FRUIT ROOM.—Give a thorough cleaning. Scrub all trays and limewash the walls.

LOGANBERRIES.—After gathering fruit, cut out old wood. Tie up new growths.

PEACHES AND NECTARINES.—Take off unrequired shoots. Tie in new wood. Expose fruits to sun. Do not let the borders get dry.

PESTS.—Keep down woolly aphis, wasps, ants, etc. Hay-band or grease-band.

PLUMS.—If carrying heavy crops, support lower branches with props.

RASPBERRIES.—Cut out summer-fruiting canes. Tie up new canes to wires. Give slight mulch if this has not already been done.

STRAWBERRIES.—Make and plant new beds. Water runners after planting. Clean up old beds. Hoe and water well, and give a good dressing of fertiliser. Sever layers from parent plant if wanted for forcing. Stand pots on boards at foot of wall.

WALL FRUITS.—Give copious supplies of water. Net plums. Train in sh oots of young trees before wood ripens.

VEGETABLES.

BEANS, RUNNER.—Water and feed well. Give a light mulch of manure. Pick when young.

BROCCOLI.—Plant out the remainder.

BRUSSELS SPROUTS.—Sow a small quantity of seed now. Prick some out into nursery beds, and leave remainder untouched.

CABBAGE, SPRING.—Make another sowing. Water drills if ground dry. Transplant early sown seedlings.

CARROTS.—Thin carefully late sowings. Sow horn varieties now.

CAULIFLOWER.—Sow in boxes and place in a cold frame. Prick off into frames.

CELERY.—Remove decaying leaves and growths. Tie up with raffia. Give another earthing up after a good watering. Pick off leaves attacked by maggots, and give an occasional dusting of soot.

ENDIVE.—Sow now. Prick out seedlings at end of month.

ONIONS.—Sow now on south border. Give a dressing of wood ashes and lime before sowing. Use such varieties as White Lisbon or Ailsa Craig. Bend over tops to assist ripening. Do not store until quite dry.

SPINACH AND TURNIPS.—Sow now for winter supplies. Thin soon.

SPINACH BEET.—Give soaking of liquid manure. Make a final sowing.

TOMATOES.—Do not over-feed or water those outside. Gather fruit before quite ripe, finish ripening on greenhouse shelf.

VEGETABLE MARROWS.—Thin out weak shoots, water well and feed occasionally.

WINTER GREENS.—Continue to plant out as the ground becomes vacant.

FLOWERS UNDER GLASS.

BEDDING PLANTS.—Take cuttings. Insert in sandy soil in boxes and stand outside in cold frame. Sow Centaurea candidissima in boxes. Place in frames, pot when large enough.

BULBS.—Pot up early batches of Roman hyacinths, Paper White Narcissi and prepared Dutch hyacinths. Plunge in ashes outside. Pot up crocus species, lachenalias and freesias in 6in. pots, and keep in cool quarters in frames; plunge up to rims in fibre. Pot Lilium candidum in limy compost, and plunge in ashes up to rim of pots at foot of a wall.

CACTI AND SUCCULENTS.—Propagate now.

CALANTHES.—Feed well when showing flower. After flowering decrease the supplies of water.

CALCEOLARIAS, HERBACEOUS.—Pot into 3in. pots at end of month.

CAMPANULAS.—Pot in 8in. pots those required for greenhouse decoration and stand outside.

CARNATIONS.—Pot up rooted layers of malmaisons and return to frames. Pot layers of border carnations.

CHRYSANTHEMUMS.—Give light top-dressing when roots appear on surface. Continue tying and disbudding. Feed at intervals. Guard against earwigs.

CLARKIA ELEGANS AND SCHIZANTHUS.—Sow in pans.

CINERARIAS.—Pot on. Destroy leaf-mining maggot and spray infected plants with quassia extract.

COLEUS.—Take cuttings of ornamental varieties.

CYCLAMEN.—Feed with guano or soot water. Sow seed thinly in pans, using a fairly light compost. Shade until germinated. Prick off into pans, and put in house of moderate temperature.

FUCHSIAS.—Partly shorten back stock plants. Start into growth in warm house. Take cuttings of young growth.

GREENHOUSE HEATHS.—Propagate by cuttings. Insert in well drained pots containing sandy peat. Select small half-ripened shoots. Stand under bell-glass in cool house.

HELIOTROPE.—Pot rooted cuttings into 3in. pots.

NERINES.—Give resting period in frames. When growth commences, water and repot, using compost of rich medium loam, a little sand and mortar rubble.

PRIMULAS.—Feed. Pot on P. obconica in 6in. pots, keep cool and shaded.

STOCKS, WINTER-FLOWERING.—Pot into 5in. pots and pinch points fourteen days after.

ZONAL PELARGONIUMS.—Pinch off flower spike until end of month. Feed with Clay's. Propagate by cuttings taken from summer-flowering plants.

FRUIT AND VEGETABLES UNDER GLASS.

APRICOTS.—Tie in young shoots. Allow wood to ripen when fruit is gathered.

FIGS.—Stand pot figs outside in sunny position to ripen. Maintain a buoyant atmosphere in house where trees are still carrying fruit.

MELONS.—Ventilate more freely when fruit is ripening. Discontinue damping. Remove useless growth gradually.

ORCHARD HOUSE FRUIT.—Place trees outside when fruit is gathered. Do not let roots get dry. Plunge pots up to rims in ashes, and water frequently, and give a light mulch of decayed manure.

PEACHES AND NECTARINES.—Syringe forcibly to keep down red spider directly fruit has been gathered. Do not let roots suffer from lack of water.

VINES.—Give muscats a drier atmosphere when ripening. Leave top air on at night. Exclude wasps by covering ventilators with tiffany. Half-prune early vines and spray to keep down red spider. Place a layer of clean straw over borders in late vinery to conserve moisture. Plunge pot vines outside

CUCUMBERS.—Keep temperature warm and moist. Apply liquid manure frequently.

TOMATOES.—Top-dress, if this has not already been done. Re-pot June-sown plants and keep them growing sturdily near the glass. Fumigate at once if white fly is seen.

Digitized by Google

SIMPLE GARDENING

WHY SOME GARDENERS FAIL WITH PLANTS.

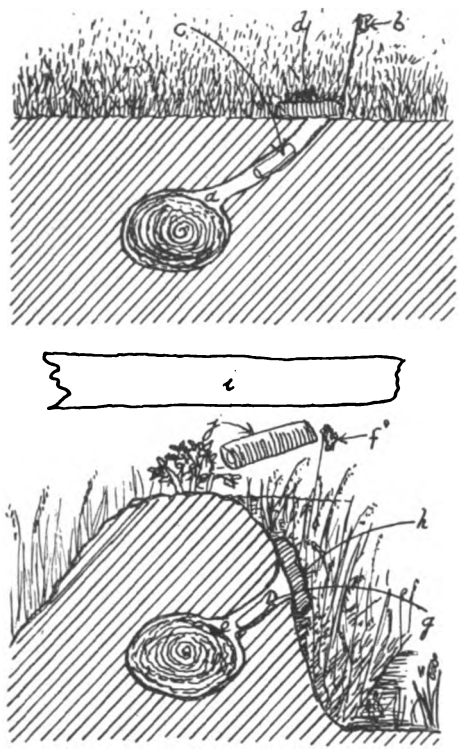
GARDENERS are greedy as well as generous. They are, as a class, exceptionally generous; if they succeed well with certain plants, and a neighbour or visiting friend does not possess these particular plants, few things give more pleasure than that of a presentation of some of the stock to someone else. They are also greedy in another way, in that they wish to grow many plants—too many for the accommodation afforded—and the results are disappointment, chiefly to themselves. This kind of greediness is, really, excusable, as one is so often tempted to grow one hundred plants when there is only room for fifty. Of course, there are isolated cases where an expert cultivator can crowd in many plants in a greenhouse or stove and do them all really well. I know one such cultivator; he was, thirty years ago, an expert cultivator growing stove and greenhouse subjects splendidly, and one wondered how he managed to do so, owing to their size and health, the structures being so small in proportion. I also know a gardener who always resists this temptation, and grows just the right number of plants to fill the given spaces, and so grows very fine specimens. The two are, almost, exceptional cases. It is, really, good policy, especially during the winter months, to avoid undue crowding of the main subjects in greenhouses and conservatories, and this is a good time to make the necessary arrangements, doing the best plants well and discarding the rest.

EARLY TRENCHING OF VACANT GROUND.

Even sandy ground is all the better for being trenched at least once in three years, and that of a heavy retentive nature, such as clayey mediums, is certainly much improved. Very light soils may be dealt with in this respect, any time during the winter, with good results; but stiff soils cannot be so treated and turn out satisfactory if they are dug or trenched while in a saturated condition. The only way to deal with such ground is to ridge it, throwing up the soil in rough chunks to form ridges about 2ft. across at the base and 18ins. high. Ordinarily severe weather will then penetrate such ridges, and, in the spring, the soil, when levelled, will crumble to pieces—almost a powder—and it will be a pleasure to work it; the resultant crops, whether from seeds or plants, will thrive in it during the following summer. It does not matter how rough the plot may look when the work of trenching or ridging is done; but it would be a big mistake to meddle with such trenched or ridged soil while it was, later on, in a pasty condition. If left undisturbed, the soil will dry sooner than if it was forked up prematurely. I may urge similar treatment for new ground, ground now all weeds and rubbish or good grass. As soon as possible, the turf of such ground should be peeled off and stacked for future use, and the soil trenched. The weedy ground should be top-cleaned and the rubbish burned out at first. So we see how important it is that vacant ground should be cropped or trenched from now onwards.

WASPS AND THEIR DESTRUCTION.

Owing to the wet weather last winter and in the early spring many queen wasps were destroyed. In some districts, especially where hay and corn ricks were numerous and thatched cottages and outbuildings exist, there was ample shelter from cold and wet, and so queen wasps survived. Although fruit crops are good in many districts, we do not appreciate their destruction by hordes of wasps, rather we would destroy the latter. The netting of choice plums,



pears, apples and peaches is essential in some parts even where the nests are destroyed wholesale. The nests are dealt with in various ways, by damp and dry powder squibs, etc., but I am explaining the simplest way. The nests should be located during the daytime. Watch the wasps leaving the fruit quarters as far as you can see them, then go to that point and watch them passing a further stage, and so on to the nest; then fix a stick with a white paper on it close to the nest. The nest should be destroyed soon after sunset, when the wasps are at home. This is easily done by inserting a small roll of cloth, the size of one's finger, in the entrance hole and stopping the latter with turves and fine soil trodden down. The cloth should be saturated with turpentine. The method is shown in level ground and in banks. At *a* the nest is shown; *b*, the mark stick; *c*, the roll of saturated cloth; *d*, the stopping-up soil. In a bank *e* shows the nest; *f*, the mark stick; *g*, the saturated cloth; *h*, the stopping-up soil; *i*, the strip of cloth; *j*, the latter rolled up ready for dipping in a vessel of turpentine.

TOMATOES: LATE SUMMER AND AUTUMN TREATMENT.

To reap the best from every plant grown and fruited throughout the summer months, we should judiciously reduce the amount of foliage and stop the plants in due time. After many years' experience I have found it advisable to stop plants growing in the open air at the end of July, and about August 15th in the case of those growing under glass. On or about these dates, respectively, I pinch off the ends of the plants just beyond the truss of flowers last formed. This truss of flowers should be well shaken during the three days following. This treatment helps to distribute the pollen and set the fruits, which quickly swell and attain a large size. The leaves, also, grow rapidly; some of the lower leaves should be reduced in size if they are turning yellow or cause overcrowding. If the plants are allowed to continue making new growth, both the growth and the young fruits borne on it will be useless and do harm, because they rob the lower fruits, which have a chance of ripening, and thus reduce the weight of the available crop. Furthermore, the removal of the tops in due time allows more air and sunshine to reach the fruits, which colour better. The latest crops are borne on young plants occupying sunny positions under glass and which are now showing the first truss of flowers. Not more than three trusses should be allowed to mature on these plants.

GRAPES.

The early varieties, such as Black Hamburgh, Foster's Seedling and Buckland Sweetwater, will be colouring nicely, and the late ones hardening the stones in the berries. Where all are grown in the same vinery, it is difficult to treat all as they should be; but usually they are grown in separate houses. Now, black grapes "finish" better under a slight shade than when unduly exposed to the sun's rays; whereas the white grapes put on that rich amber colour better when they are exposed, after the stones have hardened. All varieties are liable to be badly scalded if they are exposed to the sun unduly while the stones in the berries are hardening, and the Muscats are the ones to suffer most in this respect. Approximately, the stoning process occupies eighteen days in the case of early varieties, and twenty-two in that of late ones. The berries are hard to the touch, but soft after the stones in them have hardened. The final stage of feeding should come now and end when the colour is perfect. Night air, in moderation and according to the weather conditions, is beneficial; more air, generally, should be the rule, especially through the front ventilators; but the latter should be almost closed at sunset. All sub-lateral shoots should be removed weekly.

GEORGE GARNER.

IPSWICH FLORAL FETE

CONSIDERING the prolonged drought that has been experienced in this district, and the heat wave that occurred before and during the Show, it was a matter of congratulation that the exhibits were so good as those shown at Christchurch Park on Wednesday, July 15th. For a droughty season the exhibits in practically all classes were exceptionally fine. Pride of place and attention in the floral exhibits were accorded to roses, which were very good. Especially attractive was the large group of cut roses erected by E. J. Hicks of Hurst, Berks, and granted the silver challenge vase. Closely following in point of excellence were the exhibits of F. Cant and Co., and B. R. Cant and Sons, and Messrs. Allen, in whose group the dwarf polyantha Orange King was prominent. In the open classes for cut roses (thirty-six blooms), Messrs. F. Cant were first, B. R. Cant second and D. Prior third. The first-placed exhibit won the silver challenge bowl, and in the second prize lot was the premier individual bloom of the Show—J. G. Glassford. The amateur classes were fairly well filled and some good blooms staged.

Sweet peas were another striking attraction. Messrs. J. K. King put up a representative group of good varieties, prominent among which was Royal Scot. It secured for them the silver trophy. In the vase classes there were some exceptionally good displays, the first prize exhibit for nine vases being quite striking. This was staged by A. E. Garrod, the other prize-winners being Dr. Turnbull and Sir G. Ryan. Space will not permit of our referring to all the exhibits in this and other classes which really merit mention.

Carnations were not quite so prominent, but there were some good flowers. A fine display secured for H. Lakeman a silver bowl, and he was also successful in other classes in the open section. There were some good vases of hardy flowers, but in these classes competition was not so strong, the hot weather obviously being against the showing of these flowers.

Considerable space was given to floral decorations, and these were a feature of the Show which was, evidently greatly appreciated by the visitors. There were some distinctly artistically decorated dinner-tables, the work of the judges being by no means easy. Bowls and baskets of flowers were also a striking feature.

In the classes for grapes, white and black, Mrs. Jump and F. S. Stevenson were first and second in each case. Mrs. Jump also staged some fine nectarines and peaches, meriting the first award. Small fruits were fairly well represented. Although one could realise the ill effects of the drought by the number of the exhibits, there were some fine vegetables, especially of potatoes, peas and vegetable collections. In the main collection the prizes were awarded in the following order: J. Cobbold, Major Vivian, W. Reavall.

Taken as a whole, and in view of the adverse season, it was a Show of which Ipswich might well be proud, and reflected great credit on those responsible for the arrangements.

BOOK REVIEW

FROM America we have just received a volume which will probably, in years to come, rank as a classical contribution to the already long list of horticultural works. It is the story of a garden—a great garden, which already, after fifty years of its life, ranks as the finest institution of its kind in the world—and it is called by a most unpretentious title, "America's Greatest Garden," by Ernest H. Wilson (published by the Stratford Company, Boston, Mass., U.S.A., price $3.00). The author requires no introduction to readers of THE GARDEN, and our task is, therefore, all the more easy in bringing his latest and one of his best works to your notice. His record as a botanical explorer and collector is fully testified in all gardens, where trees and shrubs are grown, as almost every genus have been enriched to the extent of one or more of its members by his travels abroad. We owe the introduction of many of our finest garden shrubs to his keenness and enthusiasm, and in this volume he tells the story of how many of these are thriving in the Arnold Arboretum, of which he is the Assistant Director. As such he is ably qualified to write such a book, and his love of this great garden and collection is revealed throughout its pages. The opening chapter tells in simple language how the Arboretum originated and what it stands for. Probably no other institution has so much to its credit as this adjunct to Harvard University. All horticulturists and, more especially, American gardening enthusiasts, are deeply in its debt.

In the next four chapters, Mr. Wilson conducts the reader through the four seasons and describes the changing landscapes in words which could not be surpassed by the brush of a master artist. Four of the noteworthy floral pageants in spring are eloquently described—the cherries, whose numbers have been so largely increased by Mr. Wilson's travels in Japan; the crab apples, the lilacs, and the azaleas, which have also been greatly enriched by the author's explorations. Some of the noteworthy collections to be found in the garden are chosen to give the reader an idea of how the Arboretum is laid out. There are the oaks and hickories, the rhododendrons, hawthorns and the great conifer group. In these chapters, all the species growing in the garden are adequately treated and described in a masterly way, and the average gardener will find these not only full of interest and enjoyment, but also full of instruction. Two chapters on Climbing Plants and Border Plants are both full of valuable information and serve as a useful guide as to what genera can be profitably employed. A few pages serve to picture what a shrub garden should be, always bearing in mind, however, that the Arnold Arboretum is a public garden, and that fact has to be duly considered. The subject of food for birds is treated in another few pages and makes interesting reading; and the book concludes with a reference to the work done by the institution, from which the reader can gauge something of the labours of its well known Director, Professor Sargent, and the author himself, which have been expended on making the Arnold Arboretum what it is to-day.

The volume undoubtedly fills a niche in horticultural literature, not only on account of the story of the Arnold Arboretum, but for the large amount of useful and general information it contains, so admirably set forth in a lucid and simple yet captivating style. A word must be said about the fifty full-page illustrations, which rank as high as the text. They are fine pictures, and what the words may not clearly describe the illustrations certainly do. The book, in addition, is excellently printed throughout and free from those blemishes which often mar the publication of such a volume.

PUBLICATIONS RECEIVED.

"Adam's Garden."—The cultivation of vegetables, tomatoes, rhubarb and small fruits. By L. E. Fox, with a prefatory note by Mr. F. J. Chittenden. (Longmans, Green and Co., Paternoster Row, E.C.4, price 2s. 6d.) A compact and handy little manual, written in a simple and lucid style which can be thoroughly recommended to those whose gardening duties are carried out in their leisure hours.

"The Garden Register," by Marion Cran. (Herbert Jenkins, Limited, 3, York Street, S.W.1).

"Garden Receipts," sixth edition, enlarged, by Higgot Owen. (Crosby, Lockwood and Son, Ludgate Hill, E.C.4, price 2s. 6d.) This is a practical booklet for a practical man. It contains a useful collection of remedies and methods of treatment for the many diseases and pests which attack garden plants, in addition to many other helpful hints.

"In Praise of Birds," described and photographed by Charles E. Raven, D.D. (Martin Hopkinson and Co., Limited, Covent Garden, W.C.2, price 14s.) A book which all bird lovers will find both interesting and instructive. Written from the amateur's viewpoint.

"Lundy: Its History and Natural History," compiled by Lewis R. W. Lloyd. (Messrs. Longmans, Green and Co., price 12s. 6d.) An interesting account of the history, including the geological, entomological and botanical aspects, of Lundy, which will prove a valuable guide to all intending visitors to the island.

"The Lorette System of Pruning," by Louis Lorette. Translated by W. R. Dykes. (Martin Hopkinson and Co., Covent Garden, W.C.2, price 7s. 6d.)

TRADE NOTE

A NEW FLOWER PRESS.

ONE of the hobbies which generally appeal to all gardeners, and many others who have a passing interest in flowers, is a means of preserving blooms of a certain flower, or, perhaps, the whole plant. There are many ways of pressing and preserving floral specimens, as botanists and collectors all know; but all these are capable of being improved. A new patent press, known as the Chelsea Flower Press, has just been sent in, and it certainly seems to provide a satisfactory means of preservation without deterioration of the specimen setting in. It consists of layers of cotton-wool placed between wire frames, over which one or two straps, depending on the size, can be affixed to keep the whole tight. The flowers are simply placed between the layers of cotton-wool, and it is advisable to put the frame out in the sun or before a fire when pressing, as the specimen dries more rapidly. The benefit of this method is that the pigment or colour of the blooms is preserved as in life, which is, in many cases, expedient or desirable. The frame is supplied in sizes from 5½ins. by 7ins. to 14ins. by 12ins., the latter size being of especial use to botanists. They can be obtained from Messrs. Philip and Tacey, Limited, 69–79, High Street, Fulham, S.W.6.

CATALOGUES RECEIVED.

Mr. T. Smith, Daisy Hill Nursery, Newry.—Hardy Bulbs, etc.

Messrs. Stuart and Co., 13, South St. Andrew Street, Edinburgh.—A well illustrated and useful list for all gardeners who wish for a good show next spring.

FOREIGN.

Messrs. Walter Blom and Son, Hillegom, Holland.—A useful List.

Messrs. C. G. Van Tubergen, jun., Haarlem, Holland.—A valuable and well illustrated catalogue, containing numerous varieties of all classes of bulbs.

Messrs. Anthony C. Van der Schoot, Limited, Hillegom, Holland.—Bulb Lists, including tulips, hyacinths, daffodils, etc., profusely illustrated.

WHITE FLOWERS IN THE WOODLAND

WHEN a garden adjoins woodland, or any kind of copse where the soil is cool or even damp, many will be the opportunities for beautiful wild gardening. There are so many plants suitable for such places that the difficulty will be to make a choice, for in this kind of planting, where it is desirable above all things to preserve those characters of tranquillity and mystery that are the chief charms of woodland, these may easily be destroyed, or at least disturbed, by the presence of such a number of flowering plants as would be bewildering by constant attraction of attention. It will be enough in such a space as an acre of ground if there are something like three main plantings of fairly large growths, and that even these should not all be in flower at the same time. It is just this restraint as to numbers of kinds that is so restful and enjoyable in the actual wild, whether it is the wood of primroses of April or the bluebell wood of May or the shaded hillside of foxglove of June, or the wide stretches of autumn-flowering grey-purple ling. So also it will be if, in some one acre of the woodland, we plant goodly stretches of white foxglove, and, to follow it, bold drifts of one of the tall campanulas of the alpine woods, either a good white variety of C. persicifolia or one of the handsome white forms of C. latifolia. The purple forms of either are also good, but the white are better, and it is the white to which these notes chiefly refer. Then there is the graceful native plant Epilobium angustifolium. The rosy colour of the natural plant is excellent on the outskirts of some wood of Scots pine, but it is the white that is the best in summer leafing woodland. It is not quite so rampant as the type plant, just a shade more refined in growth and whole aspect. It is also a valuable plant to have in the reserve garden to cut for the house.

Wide grass paths, anything from 7ft. to 12ft. in width, pass through the wood; sometimes straight, leading up to a fine tree from which other such paths radiate, while others, again, move in easy, sweeping lines, so that a certain length only is visible, and a slight turn displays a different picture. It is in relation to these especially that the groups of tall white flowers are planted. Along the path edges are good masses of common hardy ferns of the bolder kinds—male fern, dilated shield fern, and, in the moister places, lady fern, royal fern (osmunda) and other free-growing genera with an undergrowth of water forget-me-not. There is no end to the delightful inventions that may be made in such ground, to be varied or amended from year to year as conditions change and as new ideas present themselves. There is no doubt that, in time, new introductions from China and elsewhere will prove themselves invaluable for woodland treatment, where they may prove to be more at home than in the garden.

WHITE FOXGLOVES IN WOODLAND.

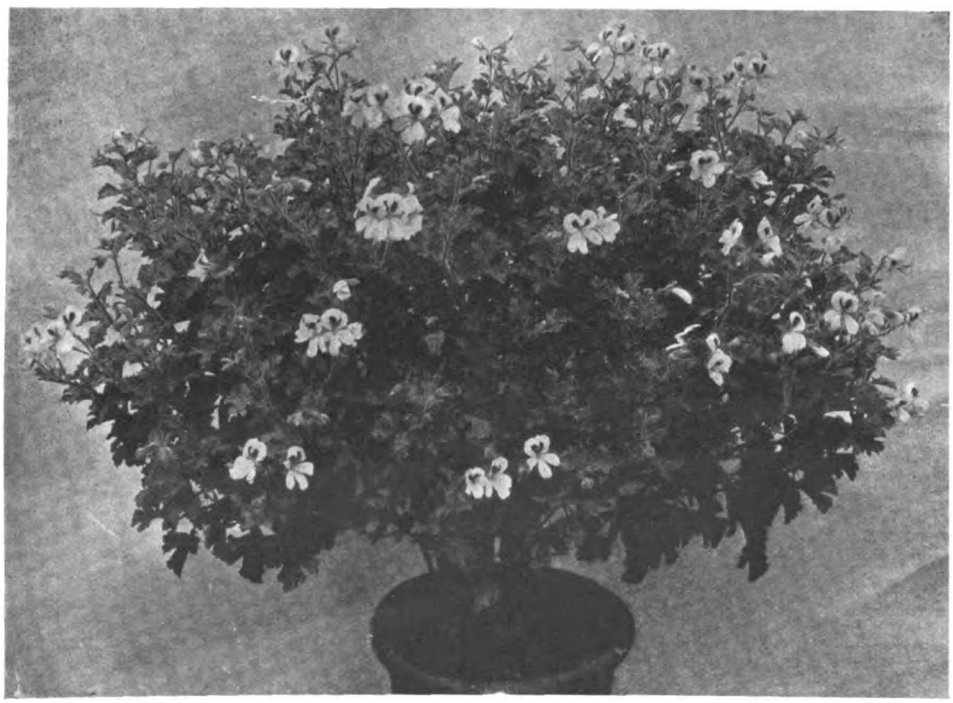
FRAGRANCE IN THE GREENHOUSE

UNDER glass one is always more aware of perfume than is the case in the open air. To begin with, it is more confined; it is stiller, and therefore the odour hangs longer upon the atmosphere. Indeed, without any fragrant flowers in bloom, there is always about a greenhouse or stove a perfume that rises from the soil and moist atmosphere that in itself is attractive, but how much more so when the favourite cherry pie or carnation is adding its quota to the whole. There is a special fitness about a fragrant greenhouse that seems more necessary even than in the sunlit borders, especially when one remembers that it is here that we must apply for the majority of our fragrant blooms, during winter at any rate.

As with the hardy garden, our perfumes are of two kinds: those that are given off spontaneously by the flowers themselves, and those that are only released when the plant is brushed against or its leaves bruised by pressure. The greenhouse is a far commoner adjunct than the stove, so that it may be well to deal first with the plants that may be grown here. The cherry pie, or heliotrope, mentioned above is not suitable for the cooler class of greenhouse; but, where a steady temperature of 55° is maintained, no plant can be found to excel it as a roof or rafter plant, for it is scarcely ever out of bloom and one may find a nice little bunch of the fragrant sprays practically throughout the year. As a standard or bush plant in the smaller houses it is equally good, though for continuous flowering there is nothing to excel an old specimen with its roots planted out in the border and allowed to run, as regards the top, more or less at will. There are, of course, many varieties of this varying in colour; while, too, some are even more fragrant than others; two that can be especially recommended being Bouquet Perfume, lilac blue, and Lord Roberts with large heads of metallic violet. Those who appreciate white flowers will find Jean d'Arc suit their taste exactly.



PELARGONIUM PRINCE OF ORANGE IS APTLY NAMED.

Carnations, of course, fill a large share of the winter demand, and by striking cuttings and stopping the plants at different seasons one may have these plants in flower throughout the year. Culture cannot be dealt with here, but one point may be emphasised in connection with taking the cuttings, and that is the need for taking the best. When the plants begin to branch from the base these push out from the stem, then more branches evolve above them and finally still more over these. It is the middle shoots that make the best and most floriferous plants; these are invariably the firmest, and therefore they root and grow most satisfactorily.

The lily of the valley is only a temporary occupant of the house and retarded crowns are used for forcing in winter and early spring, this being a very simple process where adequate heat can be maintained, and providing batch after batch of the delicate flowers within a very short period after potting or boxing. Spring, early February to nearly the end of April, is abundantly catered for by the Dutch hyacinths and the delicious freesias; while, by the earliest planting, it is possible to procure a few of the latter by Christmas and to forestall the hyacinths by a batch or two of their Roman brethren. A curious summer annual is Martynia fragrans, and this grows quickly and readily from seed when sown in March. The plants reach a height of 15ins., with broad wrinkled leaves and large flowers, something like a mimulus in form, but of a curious fawn brown colour with beautifully spotted throat. These are powerfully fragrant, with a perfume that is absolutely unlike anything else in the flower world. Another plant that provides delicious fragrance is the verbena, and with this one may take one's choice of propagating by seeds, treated as half-hardy annuals, or where named kinds such as Miss Willmott are favoured, by cuttings. Both are good, but the risk of disease is minimised by raising seedlings, and the purpose of fragrance is equally well served.

Annual daturas give good flowers that, when in bloom, leave no uncertainty on the question of perfume, a single bloom being sufficient to scent a large house. A neat grower, worthy of special praise, among these is D. cornucopiæ, with large deep purple flowers; while meteloides, which reaches a height of 3ft., with handsome white flowers tinged with violet, is another capital plant that is very easy to grow. A noble perennial form capable of reaching the dimensions of a small tree is Datura Knightii, sometimes known as brugmansia and angels' trumpets. This may be stood outdoors during summer and gives a splendid subtropical effect from May to October, for the bold leaves have a distinctly foreign look and the immense pendent white flowers, which distribute their colour far and wide, are certain to attract the attention of even the least observant of non-gardening visitors.

Acacia armata, with its fluffy little yellow balls and neat dark green foliage, is sure of a welcome in spring on account of the attraction of the plant itself, but when we add to this its sweet spring-like perfume, it is certain to find a permanent home with us. Beautiful shrubs, indeed, crowd upon us during these earlier months of the year, one of the most popular being the old golden Genista fragrans that literally smothers itself with its wee golden sprays which distribute their perfume far and wide. The charming Australian boronias, too, with their small shallow cup-like flowers are gaily blossoming and pervading the air with their subtle odour, making a striking and distinctive picture that adds not a little to the charm of the house. Two of the most lovely species of this are elatior, in rosy carmine, and megastigma, in maroon purple and bright yellow inside. Daphnes indica, rubra and alba are worth specialising and, once again, add to the array of spring-blooming shrubs. These, unlike the hardy varieties, are evergreen, and the lovely rose red or white flowers are most deliciously perfumed. For the cold house a tub of the old-fashioned myrtle cannot be surpassed, and this may spend the summer in the open air if wished, to the great advantage of the plant. Flowering in this case takes place in autumn, and where again brought under cover before the frosts, will continue to open its buds half way through the winter.

Digitized by Google

A good length of side stage might well be allotted to the scented-leaved pelargoniums, for these form a host in themselves and are ideal for culture in the cool house, where they demand no more than to be kept moderately moist and in the lightest possible position. Search will reveal an extraordinary number of these, every one of which is distinct and interesting and worth procuring. Capitatum has foliage scented like the petals of the rose. Cloringda, too, is most refreshingly perfumed, with handsome deep green leafage, added to which are the qualities of profuse production of large deep rosy cerise flowers and a very vigorous habit. Crispum is valuable for the citron perfume of its leaves; while another notably fragrant species is Duchess of Devonshire, with flowers that are very attractive —blush white heavily blotched with crimson. Fair Ellen is of the oak-leaved type; while grossularioides, with gooseberry-like leaves, is prettily variegated. Lady Mary is nutmeg scented, Lady Plymouth highly scented and charmingly variegated, Lady Scarborough with leaves remarkably like those of the parsley. Little Gem, in addition to its use in the greenhouse, has rose flowers and a neat habit that renders it very useful for edgings outside as well. Pretty Polly is prominent for its almond fragrance, while Prince of Orange—fitting name—is deliciously reminiscent of that fruit. The old tomentosum, with its powerful aroma of peppermint and soft downy leaves, is never likely to lack admirers, while Shottesham Pet reveals the fragrant odour of the filbert nut. This is a sufficiently representative collection for the ordinary house, though it might be widely extended where more are desired, for South Africa especially is very rich in many splendid species.

Writing of fragrant foliage brings to mind one of the grandest of all these plants, the lemon-scented verbena, which is really Aloysia citriodora. This as a great bush in a large pot is supreme for cutting purposes and one of the earliest of all plants to grow. Given the culture afforded to the fuchsia, including the reduction of water during the winter months, and the hard cutting back in spring, you will have nothing to complain of from your lemon plant. Indeed, there is only one criticism that could be levelled against it, and that is that it is rather prone to straggle; but this may be remedied by regular and continuous stopping of the young growths.

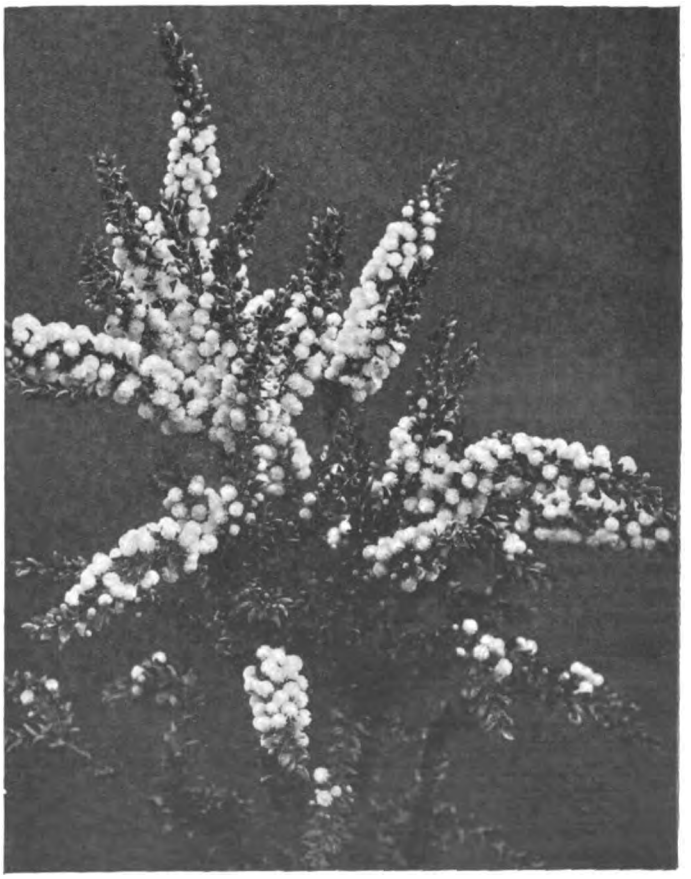
One of the most magnificent bulbs that can be grown in the cool house is unquestionably Hymenocallis callathina, the sea daffodil, while its delicious perfume deserves an equal meed of praise. This is a summer flower of large size and exquisite whiteness, while the charming form absolutely beggars one's descriptive powers. The virgin whiteness is absolutely untouched, save by a green line down the centre of each petal. Our old friend the cyclamen, so long valued for its beautiful flowers and winter-blooming qualities, has recently added to its other charms that of fragrant perfume. The Sheepwell strain is really fragrant and all the usual colours are included, while the habit and freedom with which the flowers are produced leave nothing to be desired. The common eucalyptus might not appeal to all as a fragrant subject, but the variety citriodora would not meet adverse criticism on this account. The crushed leaves are delightful and it is readily and speedily grown to a decorative size from seed.

Passing from the greenhouse to the stove, one still finds no lack of fragrant flowers, even the orchid house possessing its perfumed forms in the persons of Stanhopea, etc. Everyone knows the beautiful Stephanotis floribunda with its clusters of pure white waxy flowers, and it is doubtful if a better climber of moderate dimensions can be found where space is rather restricted. One scarcely needs to praise its perfume, for the scent distilled from the lovely flowers is world famous and speaks for itself. A more gorgeous and vigorous grower that is scarcely less familiar is the Allamanda, of which the finest species is Hendersoni. This blooms from every point and bears deliciously fragrant flowers, 3½ins. to 4½ins. in diameter, thus giving a very noble appearance when seen from beneath. Delightful for suspension in square wooden baskets or pans is the dainty Hoya bella, a very different plant from its better-known relative "carnosa." Bella does not climb but forms a small bush-like plant with short branches and similar shining green leaves, although these are on a greatly reduced scale. One fact in connection with its culture should be noted, the soil—which should consist of a mixture of peat and loam—must be used in a lumpy condition and not made too fine. The Amazonian lily, Eucharis amazonica, is one of those established favourites that is never likely to lose its popularity,

ALLAMANDA HENDERSONI IS VERY FRAGRANT.

while the beauty of its widely expanded white flowers and the unsurpassable perfume of these is in no need of comment.

H. W. CANNING-WRIGHT.



ACACIA ARMATA IS ONE OF THE MOST ATTRACTIVE OF THIS POPULAR GENUS.

FAIR CROWNS. I—OLYMPIA AND HERCULES' OLIVE

"AT the Olympic Games, an olive-crown or garland; at the Isthmus, one of pine; at the Nemean, one of parsley; at the Pythian, apples from the trees sacred to Apollo; and with us, at the Panathenæa, olives from the tree of Minerva. . . . What do you smile at? You think our prizes small, I suppose?" So queries Lucian's Dialogist, Solon. Referring again to the Greek athlete and his awards, he exults: "How they will fight for their wives and children, their religion and their country [those] who, naked and unarmed, show such an ardent thirst after victory when they contend only for apples and wreaths of olive!" A similar thought seems to have alarmed the invaders under Xerxes, when Greek deserters after Thermopylæ, explained to him the Olympic Games and the fierce rivalry for the sole reward—a wreath of wild olive. "Heavens! Mardonius," cried out a Persian warrior, "against what kind of men have you brought us to fight, who contend not for wealth but for glory?"

It was quite true, the earlier costly prizes of the local festivals at Olympia, supposed to have originated as funeral contests in honour of Pelops, had been replaced by this "precious olive." This change was also adopted by the re-organisers of three other competitive gatherings, out of which developed those famous Pan-Hellenic competitions known as the Pythian, Isthmian and Nemean games. These four great and sacred meetings were, therefore, called the "Games of the Crown," to distinguish them from the lesser athletic contests where prizes of money and valuables were still offered. Simple and poor as this leafy crown might seem to be, nothing was more treasured. That youth who reckoned time by Olympiads or Pythiads, who trained for weeks under the whiplash of his instructor, and finally bound his hair with the fillets of victory and bent his modest head to receive the leafy chaplets of olive or pine, or celery, or laurel, bestowed at Olympia, the Isthmus, Nemea or Delphi respectively, had won honours valued far beyond riches. Roman emperors longed to wear the wreaths also. One of the proudest days in Nero's grotesque life was that on which he entered Rome, clothed in purple, wearing the Olympic crown upon his head, and carrying that of Pythia in his right hand, while the rest of the thousand and odd crowns that had been awarded by the lax hands of judges in the later games were borne before him.

However, the wreaths were not really all the rewards. Not only was the lucky winner pelted with ribbons and flowers like a *prima donna* at the moment of victory, but outside of the Stadium other gifts awaited him, such as civic honours (since each delegate from a Greek State was regarded as its personal representative), and other concessions of value. Even a portrait statue might be erected in his honour. Probably, after wearing his chaplet at the evening festivities he took it home and dedicated it to his local god, hanging it up in the deity's temple; or to that god whom he thought might have helped him to victory, in the personal way that the Greeks believed possible. Each leafy spray of the verdurous crown would certainly keep green in his memory that personage or deity whom the numerous legends connected with the founding of the various games—legends which the earlier contestants probably thought were pure history.

What Olympic victor, for instance, could forget that the heroic Hercules had decreed the games? He could choose to believe the story that the hero, after cleaning the Augean stables by turning the River Alpheus through them, afterwards rested by its brink in an olive grove. There he and his companions made their rustic beds from the luxuriant foliage, and in the friendly contests of skill in throwing weapons, wrestling and the like, had playfully crowned the winners with branchlets of the same trees, including himself, and decided to renew the sports every year. Later, Hercules marked out a grove among these olives in honour of his father Zeus. This grove was supposed to have been destroyed to make room for the great temple of Olympian Zeus, whose olive-crowned statue was a Phidian masterpiece, and the corrupted Greek name for a grove survived in that of the squared space about this temple in the heart of Olympia, known as the Altis. But some said that the grove had been planted by Hercules, who, pursuing the hind of Diana, followed her golden antlers through the country of the Hyperboreans, somewhere north of the Danube, into the ". . . wan, grey olive-woods, The fittest foliage for a dream." They said he brought some home with him to plant about the altar of his father, and to shelter the pilgrims on the "thronged and sacred lawn of Zeus," then lying scorched under the blazing sun of southern Greece.

A lone, wild olive tree standing on the Altis near the temple of Zeus was known as the "Olive of Fair Crowns," and was presumably one of the very grove marked out or planted by Hercules. Whatever its origin, one can imagine how often hopeful, if weary, youths in training glanced at this tree and dreamed of the day when that boy of pure Greek parentage, and with both parents living, should come out just before the Olympic games, and cut, with a golden sickle and much ceremony, sprays from this olive—sprays which would be woven into the fair crowns laid on the gold and ivory table to entice the eye. If his gods were favourable, why should not the purple-robed judges "cast above his eyelids, around his locks, the grey-coloured ornament of olive"?

H. INGERSOLL.

THE LACE WING FLY

THE rearing of the lace wing fly might prove a profitable undertaking for horticulturists and gardeners generally, considering her helpful work in suppression of plant aphis. But the larva of the lady-bird is far better known in this capacity than any of the lace-wings, although the latter are numerous in Britain and are mostly aphis-devourers.

The lace-wing fly emerges in the month of May from an amazingly small white silken cocoon which has been cunningly concealed throughout the winter months under the fold of a leaf or in an equally obscured nook.

Once seen, the beauty of the lace-wings is unmistakable. All the species have slender bodies, differing slightly in size and colour: *i.e.*, tender green or brown. The wings are slightly longer than the body and richly veined, also covered with a lovely sheen which fades after death. The antennæ are long and tapering, and their eyes of a striking metallic hue. The eyes of the species named chrysopa, for example, are like hemispheres of gold.

Early in June, the female lace-wing seeks a suitable spot for depositing the eggs, and can often be seen at this time of the year, posing in contemplative attitude, waving her long antennæ. Her methods are both remarkable and unique.

THE ADULT INSECT.

Just before the eggs are laid, she exudes from her body a drop of gluten on to the selected spot (usually leaves or twigs infected by aphis), then, by raising her hind body to its utmost limit, the gluten is drawn upwards as a thread, and before this has time to harden in the air an egg is lodged on the top. She repeats this action for each single egg, and, the insect's body being her gauge, these unique stems are of regulated length. When the eggs are grouped three and four together (as by some species), united at the base like a bunch of cherries, then one drop of gluten serves that group. These eggs will be very difficult to find; either in single or double rows, or in groups, placed on leaves and branches of elder or other trees and plants abounding with aphis upon which the grub will feed when hatched.

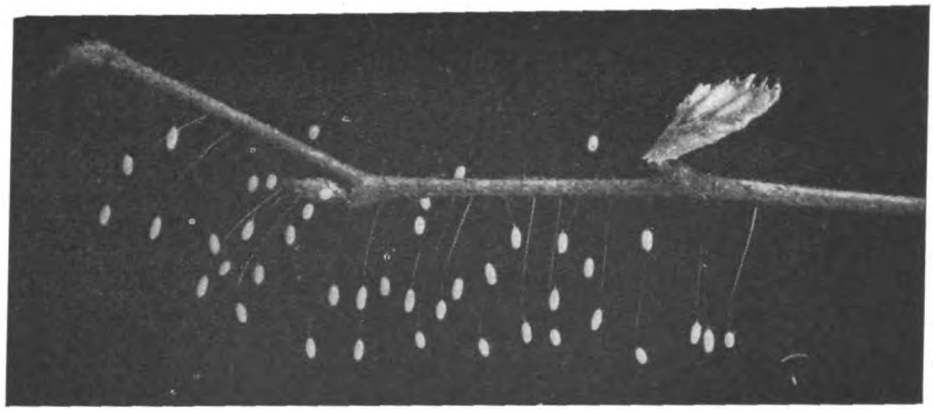
These eggs are so minute and delicate that even scientists have mistaken them for fungi, being not unlike the apple-fungus, with small oval-shaped greenish-white heads and transparent stems about three-quarters of an inch long.

Evidently the design of these foot-stalks is to protect the eggs from the attacks of the lady-bird larvæ, etc.,

Digitized by Google

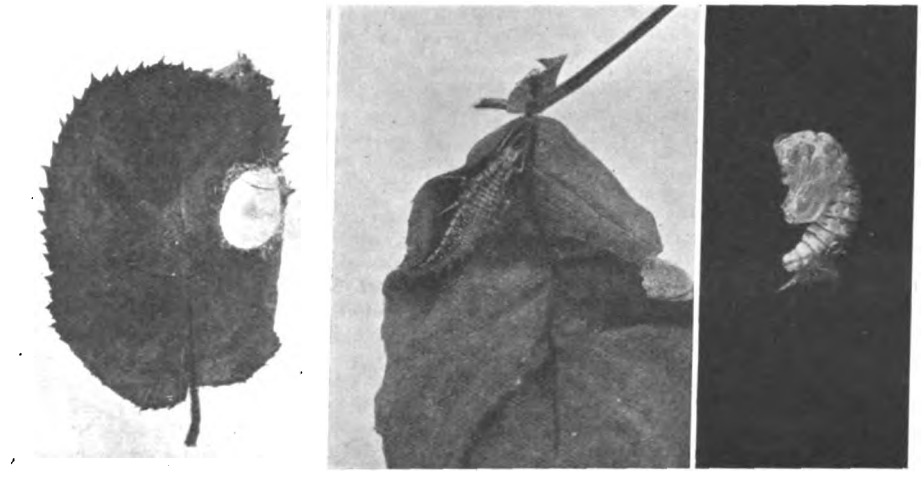
which frequent the same situations. Also the stems are too smooth and slender for the enemy grubs to climb—this has been proved by experiment. David Sharpe has given us very interesting diagrams of the specially constructed claw of the larva of the lace-wing fly, as seen under a powerful microscope.

When, after about ten days, these eggs are hatched, the grubs are no larger than pin-heads, but quickly attain full size and attack the aphis provided by the mother's foresight. One chrysopa larva was captured in Kent last summer and brought to London on August 12th. He first attracted the writer's notice by scuttling across the table on which flowers recently brought in from the garden had been lying.



THE EGGS MAGNIFIED ABOUT THREE TIMES.

In appearance, it was a phenomenal round bundle of fluffiness (the size of a very small lady-bird), mysteriously propelled, till the magnifying glass revealed the camouflaged body of an insect with six tiny legs, and the "bundle of fluff" proved to be fragments of wings and other particles of aphides, the insect's victims; mandibles not unlike the forceps of an earwig could be seen just projecting beyond this gruesome burden. The insect was kept in an empty matchbox and given occasional runs upon aphis-infected leaves when these could be obtained, and its intelligent manœuvres were watched with intense interest: magnifying glasses were at a premium. And this is what took place.



COCOON. LARVA, OF CHRYSOPA FLAVA. AND PUPA

This larva "nosed" its victims after the manner of a fox-terrier scenting rabbits, moving its head from side to side. Having found his aphis, he speared it with a special apparatus in the jaw (called a sucking-spear), sucked the morsel dry, and then, with a clever jerk of the head, flung the remains on to his back with marvellous precision, and hurried on in search of more prey. Green aphides were not easy to obtain in London, and, as the insect appeared to be pining for a more natural life, he was liberated in Kensington Gardens early in September upon some rose branches overhanging the gates of the Dutch garden.

The results were satisfactory, for the larva was soon seriously engaged, actively searching under the leaves, spearing and sucking, etc., until he disappeared from view.

SOME TIBETAN PRIMULAS

BY F. KINGDON WARD.

MR. KINGDON WARD, THE WELL KNOWN PLANT COLLECTOR, DESCRIBES THE SPECIES OF "SIKKIMENSIS" PRIMULAS FOUND BY HIM IN 1924. IT IS TO BE HOPED THAT THESE WONDERFUL PLANTS WILL SOON BECOME COMMON IN GARDENS.

EVERYBODY knows Primula sikkimensis, and most gardeners are acquainted with the "sikkimensis" primulas in general—a very natural group which includes also the well known P. secundiflora. They are easily recognised by their usually terminal umbels of drooping flowers, and by the fact that, seen in profile, the line of the corolla is continuous with that of the calyx. Botanical characters are the long narrow capsule projecting far from the calyx, and the oval or slightly coffin-shaped—but not angular—seeds, flattened on one side.

The "sikkimensis" primulas are closely related to the "candelabra" primulas, though one need never confuse them, bearing in mind the above-mentioned diagnostic marks. Both have much the same habit, sending up a single tall flower scape from a crown of large leaves; both rejoice in open meadows, more or less marshy, or along the banks of streams and the margins of woods; both tend to produce whorls of flowers—in the "candelabra" section this habit is characteristic and a good diagnostic mark, but it is by no means rare in the sikkimensis section; and finally, both are divisible into two colour groups, (i) yellow-flowered and (ii) purple-flowered.

But there the resemblance ends, and it will be seen that it is, after all, superficial. The "candelabra" capsule alone is decisive—spherical, enclosed in the calyx, instead of narrow cylindrical, projecting; the flower outline, too, is distinct, the corolla limb making an angle with the line of the calyx, and the flowers never drooping; lastly, the "candelabra" seeds are small angular cubes, like tiny lumps of sugar, and much darker in colour than "sikkimensis" seeds.

It is a well known fact that the "candelabras" hybridise freely, and consequently for garden purposes there is probably no other class of primulas to touch them. Undoubtedly they are the garden primulas of the future. Fine, sturdy, upstanding plants, they are perfectly easy to cultivate, taking care of themselves, crossing among themselves, and seeding freely. The purple-flowered PP. japonica, pulverulenta, Beesiana and Burmanica, and the yellow-flowered PP. Smithiana, Cockburniana, Bulleyana, helodoxa and chungensis can hardly be beaten except by their own hybrids; the flame, salmon, maroon and peach coloured crosses are as bewitching as they are bewildering, and form sheets of indescribable glowing light by the pond or along the stream bank. I have always felt that,

Digitized by Google

as a group, they have only one serious rival, the "sikkimensis" group. As already mentioned, these are closely allied, but easily distinguished; they also contain a purple-flowered and a yellow-flowered group.

But here comes the difference—and, from the horticultural point of view, it is an important one: no one has ever succeeded in crossing a purple-flowered "sikkimensis" with a yellow-flowered one, and it is not from want of trying, either. The purple cannot be broken down; it appears to be as stubborn as the yellow—the two refuse to hybridise.

I do not maintain that the "candelabras" hybridise in nature. They may do so, but I have never seen it, nor should I expect to do so once in a score of years. For the illegitimate seedlings, where hybrids and species are coming up side by side, are sure to be decently suppressed—in a closed formation, of course, *no* young plants could survive.

Moreover, the species, yellow and purple, tend to keep to their own localities and to flower at different times. This is particularly true of the "sikkimensis," though I have seen the yellow-flowered P. sikkimensis and the purple-flowered P. secundiflora flowering by the thousand—a sulphur sea streaked with blood.

But in the garden, where every seedling gets a fair chance, it is a different matter; here the hybrid can compete on equal terms with the species, and is, in fact, often given exceptional treatment, eliminating all competition. And yet the purple-yellow "sikkimensis" cross has baffled the experts.

PRIMULA SIKKIMENSIS AT 12,000 ft. ON THE FRINGE OF MEADOWLAND ON THE TIBET BORDER.

To return to our "sikkimensis" section, we find a Chinese and a Himalayan representation, though recent exploration has shown that these areas are by no means isolated.

The section is represented in Sikkim only by P. sikkimensis itself, and the late Professor Bayley Balfour stated at the Primula Conference, in 1913, that no purple-flowered species was known from the Himalaya.

Western China has given us eight or ten species, however, both yellow and purple flowered, of which we may mention P. pseudosikkimensis, which, in so far as it differs (if it does) from P. sikkimensis, is an inferior plant; P. secundiflora—from which P. vittata may differ in the herbarium, but does not do so in the field; P. flexilipes and P. firmipes, which are dwarf forms; P. reticulata, which is little more than an anæmic P. sikkimensis; P. microdonta; and, on paper at any rate, one or two more. So much for the known, or alleged, Himalayan and Chinese forms.

Let us now turn to Tibet. In 1904 there was collected, near Lhasa, by Mr. Walton, a member of the Tibet Mission, a primula of the sikkimensis type, to which Sir George Watt attached the name P. Waltoni, though the plant was actually described by the late Professor Bayley Balfour much later. (See Notes, R.B.G. Edinburgh, No. XLI.) The species is represented only by two sheets in the Calcutta Herbarium, and the flowers are described as violet. No seed was collected.

In 1923 Mr. G. H. Cave of Darjeeling sent to Edinburgh seed of a "sikkimensis" primula collected in the neighbourhood of Gyantse. This has recently flowered at Edinburgh, and has been referred to as P. Waltoni; when I saw it in flower, I recognised it as closely allied to a series of coloured "sikkimensis" primulas collected by us in Tibet in 1924. It has the typical sikkimensis foliage and flower, but the corolla is a sort of crushed strawberry colour with a well defined band of cream-white meal painted over the inside, leaving only the lobes free.

These highly coloured sikkimensis primulas occur abundantly in the alpine meadows of Kongbo Province on both sides of the Tsangpo. There is a wide range of colour, from violet through maroon, purple and sulphur to pure white; but, whatever the ground colour, there is always the same thick layer of cream powder on the inside of the corolla, and all are fragrant.

The important point to notice is that these colours occur mixed in the same meadow, and in varying shades, though it not infrequently happens that one colour predominates in one locality, or even occurs to the exclusion of other colours. On one occasion we passed through a meadow where grew thousands of violet-flowered plants only, so that it was a simple matter to collect seed of that form, and keep it apart; it will be interesting to see whether it comes true.

Usually the colours were so mixed, however, that no attempt was made to separate them; it would have required an elaborate system of marking individual plants, and that scarcely seemed worth while, except in the case of the rarer whites, of which a few plants were marked to make certain that seed was secured. But will they come true?

Tibet, therefore, offers us, if not purple-yellow hybrids, at any rate flowers of all colours; and whether these are hybrids or not hardly matters. There should be no difficulty in making this group hybridise, certainly among themselves, possibly with pure yellows and purples, which also occur in Tibet.

We are justified, therefore, in expecting great things from these coloured "sikkimensis" primulas, which ought to prove just as easy in cultivation as P. sikkimensis itself; attractive as they undoubtedly are, they open up even more alluring possibilities, and will probably share with the "candelabras" the honours of the future as garden plants for everyone. Nor are these the only "sikkimensis" primulas in Tibet. Though P. sikkimensis itself does not occur, it is replaced by two fine yellow-flowered species, the "giant cowslip" primula (P. Florindæ) and the "moonlight" primula, an exquisitely scented plant; while the purple-flowered group are further represented by the fine "ruby" primula. The dwarf species of the flexilipes type are also represented by dwarf alpines.

If we regard Tibet as the original home of these plants, there is little difficulty in understanding their present distribution, and the occurrence of identical, or almost identical, species in places so far apart, and as botanically isolated, as Sikkim and Yunnan, or even Kansu; for they would radiate out from the Tibetan plateau, east, west and south, over the mountain passes. In Tibet they are on internal lines of communication; and it is remarkable how widely these plants are distributed on the plateau itself, from Gyantse in the south to Lhasa in in the north, thence eastwards down the Tsangpo valley for two hundred miles to the entrance of the great gorge.

We might even explain this "sikkimensis" colour complex on the facts of distribution.

In Sikkim we have P. sikkimensis, and in China P. pseudo-sikkimensis (practically the same thing) and P. secundiflora. These may be regarded as fixed species, sprung from the same

Digitized by Google

THE MOONLIGHT PRIMULA ALONG WITH IRIS SPECIES.

original Tibetan stock, which consists of species in a state of flux, or incipient species. If our coloured species are something like the original stock, we may be able to pick out reds, violets and purples in a nascent state, as it were, and by crossing produce a fine range of colour, from infra-red to ultra-violet. But this does not explain why the "candelabras" cross so freely at home, for, though there are no Sikkim species, the Chinese species seem fixed enough. They scarcely reach the Himalaya proper, though the occurrence of P. chungensis—the only "candelabra" we found in Tibet—north and south of the Tsang-po bend, is curious; I discovered this species originally north of Likiang, 500 miles east of this point.

The following is a list of the "sikkimensis" primulas collected by us in Tibet last year:

K.W. 5746 ("Moonlight" Primula). Height 18ins., flowers sulphur, rather large, very fragrant. The first to open, in early June, lasting till the middle of August, but at its best in July. Forms sheets covering the wet pastures at 10,000–12,000ft. in a certain valley, but apparently local. There is a dwarf alpine form, probably collected under the number K.W. 5906. I am not sure whether this is a new species or not, but at any rate it is not in commerce. Seeds germinating freely.

K.W. 5781 ("Giant Cowslip" Primula). Height 3–4ft., flowers cowslip yellow, in an immense mop, about sixty to eighty, fragrant. Opens towards the end of June, continuing to flower till the end of August. Leaves very large, petiolate, resembling those of Caltha palustris, Grows in running streams, and forms vast colonies on steep bog slopes where the water is moving freely, always under trees. It is a true woodland plant. Quite the finest primula we found and a very distinct species, which I have described under the name P. Florindæ.

K.W. 5818.—This is the highly coloured variable meadow plant. One packet of seed collected under this number is the violet-flowered form. The other packets contain assorted colours, collected from three different localities, and from both sides of the river. It is a plant of the open sub-alpine meadows, where the ground is not especially boggy, and is found also in the alpine region on steep grass-clad slopes, and in glades in the forest, along the side of the path, between 10,000ft. and 13,000ft. altitude. Height 15ins., flowers all colours, fragrant. From mid-June to the end of July.

K.W. 5906.—This is probably mixed seed, containing an alpine form of the "Moonlight" Primula (5746) and a distinct species, of which there are herbarium specimens numbered 5906. Seed was collected from three localities. Dwarfs with bright yellow fragrant flowers, found on very steep alpine gravel slopes, among dwarf lonicera, rhododendron, etc.

K.W. 6094 ("Ruby" Primula).—Plant of 18ins., with flowers of a wonderful deep glossy port wine or ruby red, and unusually large. Found at 13,000–14,000ft. in high alpine meadows, and bordering small streams, among stones. Seed of this species was not collected till January 3rd, by which time most of the capsules were empty. Nevertheless, it has germinated freely. Flowers in August.

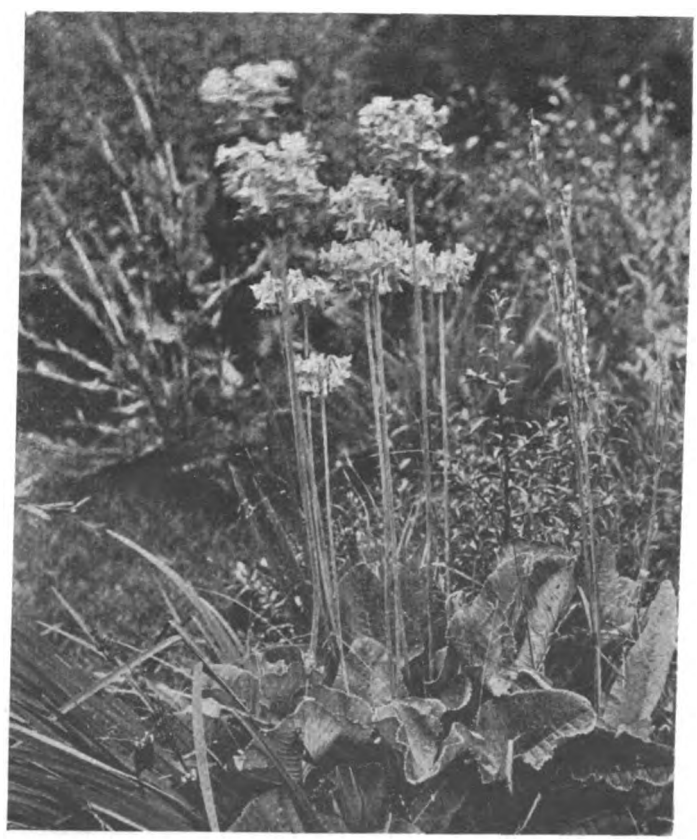
K.W. 6117.—This is a 2ft. plant closely resembling, if not identical with, No. 5818, but in white and yellow tones only. It is, however, remarkable in one respect, it normally produces three, and not infrequently four, whorls of flowers, like a "candelabra." It will be recalled that this is a good diagnostic mark of the "candelabra" section. But in P. Cockburniana there is a tendency to suppression of whorls, only two, or sometimes three, being produced (at least, in this country), as against six or seven in such species as P. helodoxa or P. Burmanica. And now we have a true "sikkimensis" not content with the two whorls as in P. vittata, but launching out into three or four, like a "candelabra." It is difficult to escape the conviction that the "sikkimensis" and "candelabra" primulas are descended from a common ancestor.

I might here refer to the two purple-flowered "sikkimensis" primulas, P. vittata and P. secundiflora. The late Professor Bayley Balfour distinguished them by their foliage, describing those of P. secundiflora as oblong elliptic, horizontal in a rosette, those of P. vittata as elongated erect. This was at the Primula Conference in 1913. The late Reginald Farrer, commenting on this, pertinently remarked that the Professor's own photographs rather reversed this!

Comparing them in a garden recently, I noticed that the flowers of P. secundiflora usually droop all to one side, while those of P. vittata hang all round the stem, and are nearly always in two whorls. But there is nothing to show that these are not merely growth forms, and, indeed, one can easily find connecting forms. Growing the two mixed up together in sufficient quantity, I would defy anyone to pick out which was which; personally, I regard them as one and the same.

K.W. 6430.—This is a plant I did not see in flower. Seed of it was sent me from Gyantse, where the plant grows along the irrigation channels. The colour is described as maroon. Evidently this is P. Waltoni, which is a plant of the Tibetan plateau.

Finally, our solitary "candelabra," K.W. 5682, Primula chungensis. It is a bigger plant than P. Cockburniana, growing 30ins. high, with bright orange flowers, not so blood orange as those of P. Cockburniana. It is a woodland plant, growing in deep shade, and flowering in June.



P. FLORINDÆ. THE "GIANT COWSLIP" PRIMULA.

HERBACEOUS FLOWERS AT VINCENT SQUARE

HERBACEOUS and hardy plants formed the principal feature at the ordinary fortnightly meeting of the Royal Horticultural Society, which was held on July 28th last. The bright and warm colours of the phloxes and sidalceas were tempered to some extent by the more delicate tones of the carnations, roses and foliage plants. Among the chief exhibits were the stands of magnificent gladioli arranged by Messrs. Kelways and Messrs. Unwin. The rapid strides that have been made within the last few years in the improvement of this flower were clearly evident, if one could judge from the general habit, size, colour and floriferousness of the sprays exhibited. Year by year, novelties with some outstanding characteristics which single them out from the productions of previous years make their appearance, and one is left in a rather undecided frame of mind as to what the ultimate result will be. As with the sweet pea, so with the gladiolus, we await the arrival of a new type which will bring along with it new blood to be introduced into the older varieties. Then we shall witness a decided change; but meantime, the process is a slow one. Fruit, principally gooseberries in excellent condition, was in the capable hands of Messrs. Bunyards, Messrs. Laxton and Messrs. Hemsley. Considering the time of the season and the somewhat trying climatic conditions, the show was a most representative one.

Most certainly one could not fail to admire Messrs. Unwin's excellently arranged stand of primulinus gladioli. The general lay-out was quite an innovation in the method of staging. The spikes of really fine blooms were shown off to distinct advantage in tall spray golden vases and baskets, and the general effect was excellent. One of the most notable varieties, all of which were hybrids of G. primulinus, was Vermilion Scarlet, the colour of the medium-sized flowers being of deep scarlet and the petals of good velvety substance. Butter Boy (of a soft butter yellow colour) and Souvenir (deep yellow) looked well interspersed among the more delicate pink hues of Maiden's Blush and the glowing salmon pink blooms of Early Sunrise. The blooms were all in fine condition and the spikes were well flowered.

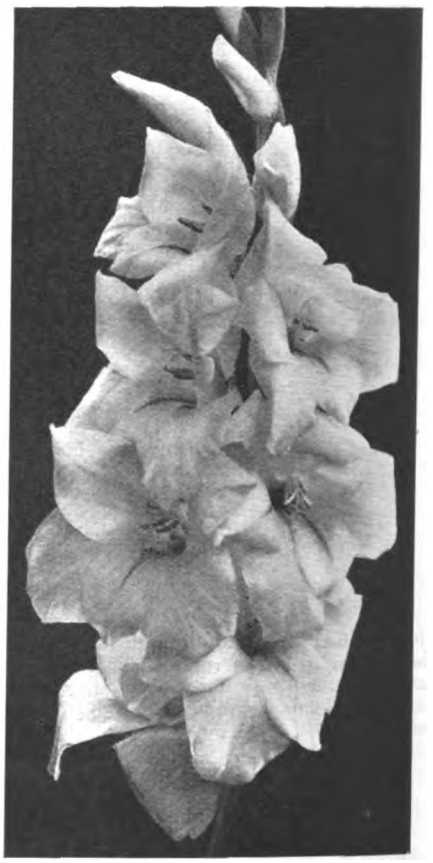
A magnificent and well arranged collection was also to be seen on Messrs. Kelway's stand. Messrs. Kelway's name is almost synonymous with gladioli, and one always looks forward to finding many interesting things in their collection, and certainly not in vain. Included in their stand was a number of the large-flowering varieties of recent introduction, among which were Beau Brocade, with large and handsome flowers of deep lilac purple colour; and Kelway's Painted Lady, white with a crimson blotch. In their new Langprim varieties were Lady Ada Fitzwilliam, of a salmon-yellow colour with an orange centre; Countess Poulett yellow shaded salmon; Lady Joan Verney, orange salmon; Pride of Huish, apricot yellow; and many others in all shades. With its extensive range of colour and handsome appearance and length of flowering period the modern gladiolus should be more widely grown in our gardens than it is, and these two exhibits, we hope, will serve to create an appreciation of the many fine points, especially brilliancy of colouring, which go to make the gladiolus one of our pre-eminent border plants.

Phloxes were well represented and formed quite a bright and varied patch of colour in various parts of the hall. Mr. H. J. Jones again had a magnificent exhibit, arranged in the form of a long oval carpet, in which the most notable sorts were Etna, F. A. Buchner, the large-flowered Thor and Eugene Danzanvilliers.

The Hon. Vicary Gibbs also staged a fine exhibit, and once again our congratulations are extended to Mr. Edwin Beckett on his successful cultivation and raising of several fine seedling varieties of merit, among which we noted Minnehaha, carrying large trusses of deep pink flowers with a deeper eye; Mrs. E. Beckett, pinkish white; Purple Emperor; Snow and Dairymaid, white. Another fine exhibit was that staged by Messrs. Rich and Co., Bath. Their collection included such varieties as Maréchal Foch, Titanic and Elizabeth Campbell.

Mr. William Yandell of Castle Hill Nurseries, Maidenhead, staged a fine exhibit of violas in great variety, which were much admired, in shades of yellows, purples, and even to the almost black colour of David Beatt. Although small in stature, many of the individual blooms are astonishingly handsome and very attractive.

Although gooseberries were intended to be the chief feature of the Show, there were only four exhibits of this soft fruit, two of which were very small. This was undoubtedly due to the fact that the gooseberry season is almost over. Messrs. Bunyard of Maidstone had the largest and most varied collection of gooseberries, and Mr. H. Hemsley of Crawley also showed some good specimens. Messrs. Bunyard staged over fifty different varieties, including representatives of the green, yellow, red and white types. Keepsake (green), Gunner and Sandwich Yellow (yellow), Napoleon le Grande and London (red), and Queen of the Trumps (white) were in good condition. Mr. Hemsley had some fine baskets of Crown Bob, Careless, Keepsake, Cousen's Seedling and Whitesmith. Mr. Frank Krant had a small exhibit of gooseberries and currants.



GLADIOLUS MRS. JAMES KELWAY.

THE ORNAMENTAL WINGED FRUITS OF DIPTERONIA SINENSIS.

Messrs. Laxton Brothers of Bedford staged an interesting exhibit of soft fruit which attracted much attention, owing to the new hybrid fruit—the Veitchberry—which was shown. This fruit is a hybrid betweeen the November Abundance raspberry and a blackberry, and it bears characteristics of both its parents. The berry is large, deep red in colour, similar to a mulberry, and is formed on vigorous growing canes which are almost self-supporting. The Veitchberry should prove of great value in the garden. The Worcesterberry, another hybrid fruit, was also shown by this firm. This hybrid has been produced by crossing a black currant and a gooseberry. Two well shaped varieties of gooseberries, Laxton's Green Gem and Laxton's Bedford Red, were shown on this stand.

Mr. E. G. Hunt of Barnstaple had a small but interesting exhibit of peaches and plums growing in pots. These trees were budded on the stock Prunus pumila, upon which

Digitized by Google

Mr. Hunt is experimenting. The fruit was particularly fine and healthy and the growth vigorous. The union of the stock and scion was excellent.

In many districts water lilies have flowered well this year, especially those grown by Mr. Amos Perry of Enfield, who staged a collection of beautiful varieties, among which were nymphæas suitable for water of varying depths. Marliacea carnea, with thick blush pink petals; Escarboucle, with deep red flowers; Gladstoniana, a large white variety with conspicuous golden yellow stamens; together with Richardsoni, Mrs. Richmond and James Hudson, were some of the finest varieties shown.

An unusual and decorative exhibit was arranged by Messrs. Dobbie of Edinburgh Flowering and fruiting vegetables of all kinds were set up in bold groups. Large mop heads of flowering onions, sprays of seed pods of kales, cabbages and leeks, set off by flowers of such vegetables as carrots, celery and beans, made an effective exhibit. Messrs. Daniel Brothers showed large spikes of their shock-flowered larkspur in many shades, ranging from darkest blue to deep carmine. Mr. H. Hemsley exhibited several of his new hybrid sidalceas; and Mr. Lloyd of Croydon a group of hybrid begonias known as Lloydii hybrids, some of which were a soft pink colour.

Carnations and roses added to the brightness of the floral exhibits. Messrs. Lowe and Gibson of Crawley had several good new varieties of carnations as well as many of the older kinds, all of which were of first-class quality. Doris Trayler was a new border carnation with the sweetest clove scent; John Stobart, a white ground fancy with bright clear stripes of rose; and Dr. Stone an apricot and rose fancy. Such varieties as Laddie, Coral Glow, Cameron, Ed. Allwood and White Pearl came from Messrs. Allwood's carnation nursery; and Mr. C. Engelmann showed Mrs. Richard Gerrish, Vera, Sheila Greer and Red Laddie. The splendid condition of Messrs. Stuart Lowe's carnations was most noticeable. In every variety the flowers were large, well formed, and the calyx non-splitting.

Innocence, one of the most beautiful single roses seen at the Show, was exhibited by Messrs. Chaplin Brothers. The cluster of reddish gold stamens makes a pleasant contrast against the pure white crinkled petals. Messrs. Waterers showed good blooms of Betty Uprichard, Los Angeles, Emma Wright, Lady Roundhay; and Mr. J. H. Pemberton had the deep velvety red variety Château de Clos Vougeot, Padre, The General, I. Zingari and many other fragrant varieties.

Dracænas, crotons, caladiums, nepenthes and foliage plants of all kinds were well arranged by Mr. L. R. Russell. Collections of hardy plants were staged by Mr. F. K. Wood, Messrs. B. Ladhams, Messrs. K. and E. Hopkins and Messrs. Prichard.

Alpines were shown only by Messrs. M. Prichard, who brought up a small but interesting collection which included Campanula Halli, which has a certain stiff, crinoline grace and is the only double campanula that has not sacrificed most of its beauty in departing from the type; C. Hostii alba, a good albino and a very cold white beside the warm ivory of C. pusilla alba, "la Religieuses des Près"; C. Tymonsii, rather frail and annual in appearance, but beautiful for the delicate cloudy quality of its many pale lavender flowers; Lobelia linnæoides, from the Falkland Islands, making a close carpet of dark green leaves like Linaria æquitriloba, but throwing up white flowers like small, spurless butterworts, on wiry 2in. stems; and our rare native Wahlenbergia hederacea.

NEW AND RARE PLANTS.

DIPTERONIA SINENSIS.—This is a representative of the maple family from central China, and its chief beauty would appear to lie in the handsome large pinnate foliage and the rather ornamental and conspicuous winged fruits which hang in large drooping clusters. These fruits are about 1in. long and of light brown to reddish colour, and are exceedingly attractive against the foliage. Award of merit. Shown by Mr. G. W. E. Loder, Ardingly, Sussex.

VERONICA HYBRIDA "CARNEA."—This is a much brighter and pinkish flowered form of the ordinary V. longifolia of the most common species in our borders and which thrives in any good soil. It is of strong and upright habit, reaching about 2½ft., and carries a number of long erect racemes composed of numerous delicate pale pink flowers with their out-thrust stamens. The foliage is also decidedly distinctive. Award of merit. Shown by Messrs. B. Ladhams, Limited, Southampton.

GLADIOLUS MRS. JAMES KELWAY.—A handsome variety of the large-flowered section bearing well formed flowers composed of white petals of good substance with a purplish streak in the throat of one of them. The blooms are excellently carried on the stiff, long and erect spikes. It is certainly a variety which should prove popular. Award of merit. Shown by Messrs. Kelways, Langport.

GLADIOLUS MARTHA WASHINGTON.—A rather slender variety with graceful spikes about 18ins. long bearing medium-sized flowers of good colour and substance. The colour is a shade of scarlet giving way to lighter tones in the throat, while two of the petals are streaked with very deep, almost burnt, scarlet crimson. It is a variety which will look at its best planted in beds or borders by itself. Award of merit. Shown by Mr. G. Churcher, Beckwith, Sussex.

ORCHIDS.

SOPHRO-LÆLIO-CATTLEYA MAGNET (S.-L.-C. Virginia × C. Hardyana).—In its comparatively short stature, the plant shows the influence of Sophronitis grandiflora contained in the parentage. The spike bore two flowers of medium size, with the segments compactly arranged, the sepals and petals purple-mauve, the labellum roundly formed, crimped at the margin, the outer zone rich purple, the inner area soft velvety crimson, the throat veined with gold. Award of merit. Shown by Lieut.-Colonel Sir George Holford, K.C.V.O., Westonbirt, Tetbury, Glos.

FORTHCOMING EVENTS.

Aug. 11th. R.H.S. Fortnightly Meeting, Vincent Square.
Aug. 18th. Shrewsbury Flower Show.
Aug. 26th. Southport Floral Fête (3 days)
Sept. 9th. International Flower Show (Edinburgh) (3 days).

VEGETABLES AND THEIR DISEASES

ONIONS.

THE maggot of the onion fly does a great deal of harm to the crops in spring, especially in a dry one. Usually the cultivator waits until he sees patches of yellowing plants before taking any action. As the pupa is formed in the autumn, it therefore remains in the ground all winter and, although it is more difficult to destroy the pupa than the maggots, autumn treatment of the soil is beneficial, and to this end an application of lime on the roughly dug soil will help matters. The lime will assist in pulverising the soil and render it workable at an early date, thus enabling the cultivator to form nice seed-beds. Sow at an early date, too, to get the resultant plants well forward and tough of skin before the fly lays its eggs on stems and leaves. But here, again, we should be in good time in using preventive measures against the fly itself. Make the plants and, indeed, the whole quarter distasteful to it by spraying plants and surrounding paths, etc., with a paraffin emulsion and one from quassia extract. Use these alternately every ten days. The fly deposits its eggs on the leaves and stems of the plant. Sometimes the late-raised plants are punctured just above the soil level and eggs deposited near by, and then the resultant maggots soon find their way down to the roots of the young plants, which are killed wholesale. When emulsions are applied they should be in the form of a fine spray, as it is not desirable that the "bloom" on the leaves should be destroyed.

Onion mildew has been very prevalent during the past few years, and it seems to come suddenly after a prolonged spell of hot, dry weather when rains and mists or fogs come. The spread of the fungus is, indeed, rapid in many instances, and, as it spreads from plant to plant, a keen look-out for its first attack should be kept. I have during the past three or four years relied much on "Abol," and on the first signs of mildew simply applied a proper strength dose to the affected leaves with a small sponge. This treatment was given to exhibition bulbs. For general use it may be sprayed on. The bulbs should be encouraged to swell a lot throughout July, and, as the mildew comes near the end of that month and in August, fairly good bulbs will be secured even if a mild attack does come. The "Abol" destroys the "bloom" on the leaves, and because of this I apply it to the mildewed parts only with a sponge. Only in exceptional cases should onions be watered. The soil should be deeply trenched and heavily manured, mixing the manure with the soil well below the surface. The roots will penetrate after it and, in dry weather, sustain the plants better than they would scorched one day and soaked another on the surface. Any watering and liquid feeding should be done by pouring the water into holes made 3ft. apart, thus keeping the subsoil moist. Surface mulching is very beneficial if the material be applied in good time.

CABBAGES, CAULIFLOWERS, BRUSSELS SPROUTS AND GREENS.

Last year cultivators lost many thousands of promising plants through the ravages of the caterpillar. Large breadths of fine vigorous plants were riddled and the hearts rendered useless in the course of three weeks. The small

Digitized by Google

white butterfly has been seen in large numbers during the past fortnight. Both these and the large white butterfly are collected by the thousand by schoolboys, and some good must be done; but, still, the damage is often excessive. The cabbage moth, too, will destroy the tender hearts of the plants through the action of its caterpillars, which do their fell work out of sight. A paraffin emulsion will do much good in keeping away the moths and butterflies from exhibition plants if finely sprayed on the soil about the plants. I have found quassia extract in weak doses, weak solutions of salt and water, lime, soot, and even very dry dust, preventives to some extent. But my exhibition plants—just a few of them, especially cauliflowers and cabbages—have been hand-picked twice a day in past years for several weeks prior to the shows. I do not know of any other remedies than those quoted above.

The "clubbing" of the plants does a great deal of damage, too. The gall weevil also causes swellings on the roots, the lower parts of the stems and, in the case of turnips, on the swollen base.

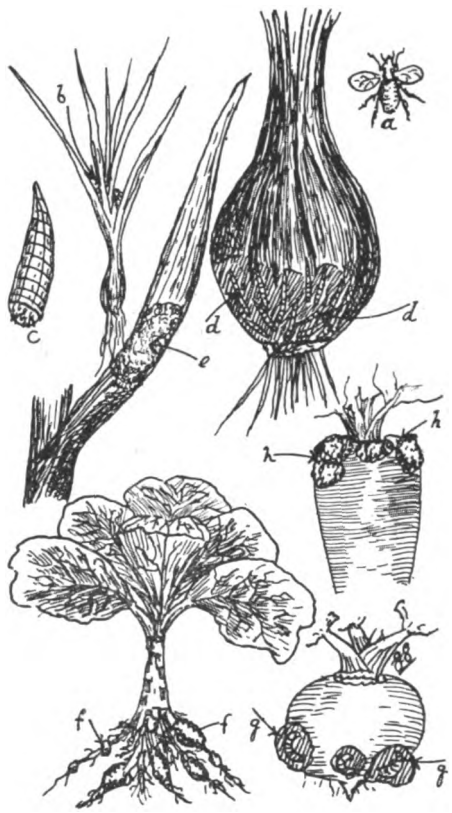
Soot and lime (quicklime) used together, under the surface—this is a very important point—will do a lot towards rendering the soil unsuitable for the growth of the club-root fungus and the gall weevil. If plants are once badly affected, they should be destroyed; if not badly affected, tread down the soil very firmly over the roots and then draw up soil as high as possible to the stems. Many new roots will permeate the added soil and help the plants to become fairly profitable. The trouble is always worse in light than in heavy soils. In one garden winter greens were grown for nearly one hundred years in the same part of it. When I took charge I found weevil and club-root trouble, so I relied on lime and common salt, using at digging time 2 pecks to 3 pecks of lime and 1 peck of salt per square rod. The digging, on account of the nature of the crops, had to be done late in winter and early in spring. Result: the first year a great improvement; the second a still greater improvement, and after the third year not any clubbing.

The seed-beds should always be equally carefully prepared, new ground used every year, and the plan of early transplanting in nursery beds adopted so that there may not be any check to growth.

CUCUMBERS.

These are often destroyed by red spider, eelworms and canker of both roots and stems. It is very difficult to get rid of the spider when once it has become established; much easier to prevent an attack. Heat and moisture assist a healthy growth and prevent red spider spreading. When the plants are syringed at closing time a very small sprinkling of fresh soot on the floor, liquid manure, or both, will keep in check red spider; dry atmospheric conditions favour its increase. Red spider breathes through its body; it sucks away the juices of the leaves and soon destroys them. Eelworms are minute creatures and enter the roots of the plants. Their effect upon the latter is to cause them to droop and become useless in spite of watering, close temperatures, etc. The eelworm is in the soil, so new should be used for a succeeding crop, the old cleared out and the walls washed with hot limewash, the bottom of the bed being sprayed freely with hot lime too. All new composts, including leaf-soils, should be sterilised.

Root and stem canker can be avoided by having the compost a few inches higher where the plant is placed and by using a compost that is on the side of lightness. It is lack of ventilation of soil and a too moist condition combined that causes this canker. If dry lime be gently rubbed in immediately the canker



a, Onion fly, slightly magnified. *b*, Eggs of the fly. *c*, Larva of the fly, greatly magnified. *d*, *d*, Grubs or maggots inside the bulb near base. *e*, Shows how onion mildew first appears on the leaves. *f*, *f*, Show club-root on cabbage. *g*, *g*, Show grubs of turnip weevil. *h*, *h*, Cankered top of parsnip.

is observed and the soil maintained in a drier state just around the stem itself, the disease will rarely spread and nature will effect a cure.

PARSNIPS.

The leaf-miner does a great deal of harm to the plants in dry springs and when cold winds prevail, which prevent the free growth of the leaves. The same remedies should be applied as in the case of carrots. But the most serious trouble arises from canker, which renders the maturing roots quite unfit for food in a short time. Some cultivators grow their exhibition parsnips on the same plot of ground year after year, but as the soil, generally, becomes very fine and light, the canker rarely does much harm to the roots. In the case of naturally clayey soils a change of quarters should be the rule every year and the soil ridged or trenched early in the winter, leaving the top portion very lumpy. Ordinary digging will not answer, and it will be advisable to do this in February just before the bed is prepared and the seeds are sown before the soil can pan down hard again. All manure used should be well rotted and applied late the previous summer or early in the autumn and winter, not any at seed-sowing time. Furthermore, it will be beneficial if 6 oz. of lime per square yard be applied in the autumn. Thin out the seedlings while very young so as not to disturb the one retained when advanced in growth. Hoe between the rows of plants weekly, it will promote healthy growth.

LETTUCE.

These plants are quick-growing, and if one crop fails another one may be raised in the course of a few days. Stem-rot is troublesome in heavy soils late in autumn and sometimes in spring among the autumn-raised plants. Extreme dampness must be guarded against, and where this stem trouble appears use old mortar rubble and lime dust when preparing the ground. Slugs, it seems, are always with us where lettuce plants are grown. Applications of lime and soot and also hand-picking are the surest remedies.

MUSHROOMS.

In some old buildings cockroaches are very destructive to mushrooms and woodlice are still more numerous, as the latter are everywhere, in public road, hedges and fields. Usually we cover mushroom-beds with straw or clean hay. But such covering material should be removed directly the first mushrooms appear and sheets of brown paper substituted, as the pests will not congregate as much under them. The hay, or straw, should be kept in a heap in a corner of the house with an odd mushroom or two, and a handful of bran placed under it; the woodlice will be found there mostly, and can be destroyed wholesale. The cockroaches should be killed with Keating's Powder, used just off the bed itself. Look for slugs at night and kill them, also place cabbage or lettuce leaves down as traps.

TURNIPS.

While the plants are in their seedling stage they are liable to destruction by the fly or flea. They should be syringed three times a week with a solution of quassia extract and fine dust at once sprinkled on, which makes the solution still more beneficial. Constant hoeing between the rows of plants helps in preventing loss through the attack of the flea. Turnips, both in a young stage and when approaching full size, are subject to club-root or "aubury," and also to the attacks of the grubs of the gall-weevil. Gas-lime, 2 oz. per square yard, applied in autumn, or quicklime, 6 oz., applied in February, will do good, also 1 peck of salt per square rod applied one month prior to sowing seeds.

THE LILIES OF EASTERN ASIA

I HAVE nothing but praise for this fine volume ("The Lilies of Eastern Asia." A Monograph by E. H. Wilson. Imperial 8vo. Pages xiv + 110. Frontispiece and sixteen plates. London: Dulau and Co., 1925. Price 25s. net.) on the lilies of Eastern Asia. The text is clear, well arranged and full of accurate information on the history, description, distribution and cultivation of these beautiful plants. The author, moreover, is the most competent authority on the subject, as he has seen practically all the species in the wild state, and observed most of them for years under cultivation. The publishers are also to be congratulated on the excellence of the paper, printing and illustrations of the book.

Wilson recognises forty-seven species of Lilium indigenous in Eastern Asia; and all these are fully treated in the text. His arrangement of the species seems to me to be sound, as it stands the test of geographical distribution. His treatment of nomenclature is critical but informed with good sense. Changes have been unfortunately necessary in some cases, but Wilson has exhausted the literature to bed-rock, and future alterations in the Latin names will be trivial or unnecessary.

As an example of Wilson's discrimination of species and varieties, I may adduce the giant lilies, which constitute a section, Cardiocrinum, of the genus Lilium, that is not represented in any other part of the world. Four distinct giant lilies have been found growing wild. The type, Lilium giganteum, is a native of the Himalayas and the Khasia Hills, at elevations ranging from 5,000ft. to 10,000ft. A lily like this grows in mountain woods at similar elevations throughout Central and Western China; but it differs in the dark stem and in the horizontal flowers, pure white on the outer surface. Wilson now distinguishes this as Lilium giganteum var. yunnanense, thereby recognising the error into which he and I had formerly fallen of believing it to be identical with the Himalayan plant. In such a case as this, when two plants, each confined to a separate geographical territory, do differ in constant recognisable characters, I consider that it is more convenient to rank both as distinct species. I would consequently adopt for the Chinese form the name given to it by Franchet, namely L. mirabile. Its habit is well shown in Plate XIV, which depicts a group of these lilies in the mountains of Western China. A third giant lily grows in Central China (Kiangsi and Western Hupeh), at lower elevations. Wilson describes this as a new species, L. cathayanum. The fourth giant lily, L. cordifolium, is wild in Japan, Saghalien and the Kurile Islands. The discrimination of these four plants is evidently a natural arrangement, establishing the existence of two quite distinct species in India and Japan, while two others in the intermediate territory of China, are found to be similar, one to the Himalayan and the other to the Japanese species.

Wilson's handling of the true lilies with large, trumpet-like flowers, which constitute his section Leucolirion, is very skilful. Here, especially among the Chinese species, there has been much confusion, now happily cleared up. There is no difficulty about the Nilgherry lily, L. neilgherrense, and the two Himalayan lilies L. Wallichianum and L. nepalense. The latter is unknown in cultivation; and the lily from Upper Burma considered to be identical with it by Baker, is proved by Wilson not to be a trumpet lily at all, being the same as L. ochraceum, a native of Yunnan, which belongs to the Martagon section. He has established beyond doubt that L. longifolium, the most abundantly cultivated of all the Eastern lilies, is endemic in the Loochoo Islands and is unknown in the wild state elsewhere.

L. leucanthum is the common trumpet lily of Central China at 2,000ft. to 5,000ft. elevation. It is very variable in foliage and flowers, but Wilson is content to recognise two forms, the type and var. chloraster, both of which were introduced from Ichang to Kew Gardens by me in 1888.

Wilson has added two magnificent lilies to this group, L. regale and L. Sargentiæ, both of which he discovered in 1903 in Western Szechuan. Closely related to these is L. myriophyllum, the typical form of which is a native of Yunnan, whence it was introduced to Kew by seed, which I sent in 1897. Its more southerly form, L. myriophyllum var. superbum, grows in Upper Burma, and was introduced by Boxall in 1899. It was named L. superbum by Baker. Wilson also includes under the section Leucolirion, a group of three lilies, with slender stems and bell-shaped flowers—L. Bakerianum from South-west China and Upper Burma, L. sempervivoideum from Yunnan (not yet introduced), and L. rubellum from Japan. It is figured in Plate VI, growing in its native habitat with Rhododendron Tschonoskii. Plants raised from the Burmese form of Lilium Bakerianum in 1891, did not prove hardy and were soon lost to cultivation. Bulbs, however, sent lately from Burma by Lady Wheeler Cuffe, have flowered at Glasnevin under glass, but made no seeds.

Wilson deals with twenty-two species of Martagon lilies, among which he includes L. tigrinum and L. speciosum. The type of this section, L. Martagon, spreads from Europe and Western Asia as far eastward as the Iro River in Mongolia. One species of the section, L. polyphyllum, occurs in the Western Himalayas. It is very charming, and has been introduced several times, but has never secured a foothold in gardens. The most southerly species is L. ochraceum, which grows wild in Siam, Burma and Yunnan. Yunnan appears to be the headquarters of this section, and three species discovered in this province have not yet been introduced, namely—L. taliense, L. papilliferum and L. Stewartianum. We owe to Wilson, who introduced it in 1903 from Western China, the pretty L. Duchartrei, which grows well amid rhododendrons at Glasnevin. It was again introduced by Farrer, and renamed after him, L. Farreri, but the closest scrutiny fails to reveal any characters by which this plant can be separated from L. Duchartrei. L. Davidii, a native of the Tibetan-China borderland, is likened by Wilson to a refined L. tigrinum, being smaller in all its parts and without bulbils in the leaf-axils. L. lankongense, also a native of Western China, is similar in most botanical characters to L. Duchartrei, but differs markedly in the racemose inflorescence and more numerous crowded leaves. It was introduced into Edinburgh in 1920 by Farrer. The singularly graceful and attractive L. Willmottiæ is a native of the mountains of Central China, where it was discovered by myself in 1888. This lily is identical with L. sutchuenense, Franchet, figured in Botanical Magazine, t. 7715, but this earlier name is invalid as Franchet based his description on a specimen that is really L. Duchartrei. The other fine species from Central China, L. Henryi, which I discovered in 1888 and introduced to Kew in the following year, is well known for its great vigour and is remarkably hardy. Wilson deals at length with two well known lilies of the Martagon section, which appear to be common to both China and Japan, namely, L. tigrinum and L. speciosum. He praises highly var. gloriosoides of the latter species, the wild form in the Chinese province of Kiangsi, and in Formosa, and says that it is the loveliest of the coloured forms of the species, and worthy of a place in every garden.

Wilson gives a lucid account of the yellow-flowered L. Leichtlinii of Japan, and of its variety Maximowiczii with red flowers, which is widely spread in the mountains of Korea and Japan. Plate XI shows a fine view of the latter plant in its native home.

The section Archelirion is restricted by Wilson, and includes only one species, L. auratum, the noblest of all the lilies as regards the flowers. It is the Yama-Yuri or mountain lily of the Japanese, and is still a common wild plant in parts of Hondo. It grows on black, volcanic soil on the margins of woods in a region with a heavy rainfall. Wilson tells the story of how the Japanese exporters exhausted the supply of the wild plant and then began growing the bulbs in rich farm land for the European market, and from this practice arose the troubles of the cultivator. He advocates the planting of small, wild bulbs in light, sandy poor soil, where drainage is perfect, and among shrubs to protect the stems and leaves from direct sunlight.

The preceding notes, which I have culled from Wilson's book, could be indefinitely extended, if space were available. Special attention must, however, be drawn to the introductory chapter on "Lilies in their Natural Haunts," from which useful hints for cultivation may be taken. He recommends the planting of lilies among ferns or dwarf shrubs, such as lavender, wild roses, ericas, azaleas, dwarf rhododendrons, shrubby veronicas and olearias. It must be remembered, however, that while rhododendrons require peat, a great many lilies detest peat. Wilson believes in mulching, and recommends covering the bulbs in autumn with rotted leaves or exhausted manure. All the species benefit from planting as early in autumn as possible. At Glasnevin, experience teaches that raising from seed is the only way to keep up a healthy stock. When raised from bulbs or bulbils, the stock of most species appears invariably to deteriorate.

AUGUSTINE HENRY.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

NOTES FROM CONTRIBUTORS

LACHENALIAS.

IT may be well to remind readers of THE GARDEN that the time is at hand for dealing with these plants if the full beauty of which they are capable is to be obtained. Bulbs planted or potted up in late July give a very different result as compared with those planted in, say, September or October, both in vigour of growth and in the lasting qualities of the bloom. The grand spikes to which an award of merit was given at Vincent Square in February were potted up in July, and were a striking illustration of the value of early treatment.

Lachenalias are ideal plants for a cold house or a frost-proof frame, and the more recent introductions include some very beautiful varieties; but to get the best out of them they should be dealt with immediately.—W. D.

CISTUS RECOGNITUS.

IN a representative collection of cistuses the subject of this note is certainly one of the most beautiful and interesting. The flowers, which appear in June, are about 3ins. across, with broad, overlapping white petals, the base of each being lit by a flare of vivid citron yellow, rayed upon its outer margin by streaks of carmine. The shrub grows about 4–5ft. high, the flowers are borne in clusters, and the leaves, as well as the flowers, bear no little resemblance to those of C. Loretii (lusitanicus).

C. recognitus is, according to Mr. W. J. Bean ("Trees and Shrubs"), a hybrid between laurifolius and monspeliensis, and it is described by him as being "close to C. Loretii" (itself a ladaniferus × monspeliensis hybrid), but with "unspotted flowers." This, it will be seen, is at variance with the above description of the shrub, as sent out by the few nurserymen who stock it, and also with that given by Sir Herbert Maxwell ("Flowers: A Garden Note Book"). Can anyone put the matter right and say what C. recognitus is or ought to be? It is probably of Continental origin, and it may be that Mr. Bean has since had reason to differ from the statements originally made in his great work. At any rate, to my unskilled eye there is little to suggest any laurifolius influence in C. recognitus.—A. T. JOHNSON.

FIGS.

THE cultivation of figs outdoors is quite simple, providing the site is a suitable one. On the south coast figs can be grown in almost any shape or form without any protection; but in cold districts a sunny wall—facing south or south-west—is essential for success.

The fig thrives best in a good but not very rich loamy soil, containing plenty of old lime or mortar rubbish, crushed bones or the like, and made quite firm—almost hard, in fact. When the trees fairly begin to grow, in the spring, they should be carefully gone over and all superfluous shoots rubbed off; while any very strong growths must either be stopped or cut back severely, but retaining the short-jointed twiggy portions, which produce the bulk of the fruit. Outdoors the figs are borne on the previous year's wood; it is seldom that fruits will mature on the current season's growth, as it does indoors.

Some protection may be needed for the trees during cold spells and a good way to afford this is to tie up the branches in bundles of bracken or hay, or hurdles covered with matting may be laid against the wall, with bracken or straw placed underneath. It is an advantage if the protecting material can be removed on bright sunny days; the hurdle over method is, therefore, perhaps, the best

Under glass, figs may be successfully grown in pots, and with judicious culture and the command of plenty of heat as many as three crops of fruit may be obtained in a year—it is quite an easy matter to get two—while in the open one has to be content with but one set of fruits. Cuttings are easily rooted in pots of sandy soil in a hot-bed, or even on a sunny border in the open. For outdoor culture Brown Turkey, Brunswick, White Marseilles, Black Ischia and Osborne's Prolific are good varieties.—R. D.

SOME HEUCHERAS.

TO some, the native heuchera means the popular species brizoides and that only; but there are other kinds of equal merit and, in addition, several fine varieties. H. sanguinea splendens has fine spikes of brilliant crimson flowers, and other varieties of this same species include the really fine things Edgehall (bright rose) and Rosamundi (rich coral pink), both free-flowering and as tall as splendens. We also like the species alba, a distinct white with very pretty foliage, and micrantha with its red stems and long spikes of small whitish flowers. HH. pubescens and Richardsoni are not, however, quite so fine as the others, although they are effective enough in the rock garden and make quite attractive plants. Profusion is our best white; Flambeau, a variety we could not miss on account of its flaring red flowers; and there is also Zabeliana, a pink, whose long stems are among the finest for cut bloom.

Heucheras should never be left to themselves. We make it a rule to lift the clumps each spring, dig the soil well and add a light dressing of manure (or guano and leaf-mould when manure is scarce), then we separate the clumps and plant the best shoots. In this way the colours remain true, the plants are strong, and the spikes both large and attractive.—HUGH H. AITKEN.

CERASTIUM ALPINUM LANATUM.

FEW of the cerastiums are much grown in rock gardens, but C. tomentosum is a well known plant in many places where, although rather too spreading in its habit, it has been appreciated on account of its silvery foliage and its wealth of white flowers, which have given it the popular name of Snow in Summer. Of the other species which the writer has put through his hands one of the most interesting has been that called C. alpinum lanatum. It differs greatly from C. tomentosum in its appearance, and, although it has white flowers also, they are not borne in such profusion nor do they give the effect of those of its sister flower. It owes its main attraction to its mats or small carpets of silvery foliage which that able grower, Mr. Clarence Elliott well describes as "like chinchilla fur which has been remodelled several times." It is emphatically a subject for the plant lover who seeks for other features than brilliant displays of flower and can find delight in such points as this. It is not difficult to cultivate in a sunny, well drained part of the rock garden in stony, sandy soil, or, better still, in a moraine. But those who live in districts where there is a heavy winter rainfall will be well advised to give C. alpinum lanatum the benefit of the shelter of a sheet of glass overhead during the winter months. No difficulty will be experienced in propagation by division or cuttings.—S. ARNOTT.

ERYTHRÆA MASSONI.

BEING of dwarf growth (never more than 6ins. high), compact habit and very free flowering, Erythræa Massoni is an ideal plant for the rockery.

The flowers, which are of a rich, rosy pink hue, are usually seen at their best in July. The plant, which is a perennial, can be increased by division in the autumn or in spring (of the two seasons I prefer the former), though, perhaps, the better method of increase is from seed. By sowing the seed, under cover, in spring and pricking off the seedlings singly into small pots or, if desired, into boxes and allowing them to remain thus for the first year, it will be found that they are strong, healthy plants for putting out on the rockery the following spring.

A light soil coupled with a sunny position will be found most suitable. It may be advantageous to cover the surface of the pocket with fine granite chips, for these, in addition to preventing the soil from becoming parched in the summer, also act as a blanket for the roots in winter.—W. H., *Glasgow*.

INCREASING HYACINTH BULBS.

A DUTCH method of securing a large number of small hyacinth bulbs is really worth trying. The plan may be carried out in the summer with any hyacinth bulbs, providing that these are well ripened and the foliage has been allowed to die down naturally. Take the bulb and, with the root part upwards, drive a knife into the underside with its point inclined towards the centre. Carry the cut all round, so that the base of the bulb is removed in the shape of a cone. This portion may be thrown away, as it is of not much use, although, on occasion, it will grow if planted. The remaining part of the bulb, which has been hollowed out in the form of a cup, is put on the shelf of a greenhouse or in any similar position where it is fully exposed to hot sunshine. In course of time, this part of the bulb, technically known as a "mother," will send off large numbers of tiny bulblets. These grow rapidly and, when they are about the size of hazel nuts, they may be gathered and planted in soil. It is rather a good plan to put the bulbs in a bed where they need not be disturbed. Rarely are flowers produced in the succeeding spring, but, in the next season, small graceful spikes are developed. While these hyacinths never display blooms of massive proportions, they produce flowers which are useful for cutting, so that the experiment is well worth while.—S. L. BASTIN.

MUTISIA DECURRENS.

THOUGH introduced many years ago, this curious climbing shrub is still very uncommon, probably owing to the fact that it has been a disappointment to so many.

In the first place, M. decurrens is quite hardy enough for most districts, in spite of the fact that it is a native of Chile and an evergreen. It appears to resent too hot a place—such as a south wall—and to have a partiality for a westerly aspect and a root-hold of light soil which is not too hot and enriched with a liberal quantity of leaf-mould. Planted on the shady side of some slow-growing bush, 5–6ft. in height, its wiry stems will ascend into the branches, to which the leaves, whose midribs end in a forked tendril, will cling with extraordinary tenacity. At the ends of the current season's shoots the composite flowers appear singly, each on a stout 4–5in. stalk. The buds of these, being a soft steely green and enclosed in a number of close, overlapping scales, rather suggest the head of a globe artichoke in miniature. But no sooner has the wonderful flower expanded its splendid rays, fourteen to twenty in number, ½in. wide and of a glowing orange-vermilion, than the likeness to that prosaic vegetable is suddenly transformed into that of some glorified gazania.—N. W.

A REQUEST

I HAVE received a letter from an old and valued subscriber to THE GARDEN, and one who often sends in extremely valuable contributions to the paper. In it he says: "I know that a letter (in THE GARDEN) from those possessing exceptional gardens would give me infinite pleasure, besides helping one to grow plants at present unknown."

I have written several times before on the subject of co-operation between a horticultural paper, like THE GARDEN, and its readers, and I feel that an editorial staff cannot do better than try to explain that one of its main uses is to act as a clearing house for all information dealing with every imaginable class of gardening subject. We try to cater for every class of gardener, from the specialist to the tyro, and we believe that we succeed, but there is always more that can be done.

However good and authoritative an article may be, it can never be said to finish a subject, and there is no doubt that there is more knowledge, infinitely more, locked up in the heads of gardeners throughout the British Isles than has ever appeared in print. It is the duty of an editorial staff to tap this knowledge and issue it in the most suitable form. Our difficulty is in getting gardeners to write. I suspect that they are a shy race, but for the common weal this shyness should be overcome. In the future we hope to increase our Correspondence and Notes of the Week pages without lessening the importance of our main articles. This, however, is impossible without the co-operation of our readers, for we are proud to say that every note in these pages has come, unsolicited, from our readers. It is only fair to state that these must contain something of interest to the gardener to make them worth publishing, but there is so much to be learnt, even about the commonest plants in the garden, that this presents no difficulty.

The letter from which I have quoted deals with rare plants, such as may not interest every gardener, but there is room in our pages for information about everything, and it makes no difference whether the note is about some slight—and successful—change in the method of growing cabbages or some mention of a new or rare plant. There are plenty of species and varieties in this country to please everybody. What is usually lacking is knowledge: knowledge of habit, knowledge of growth, knowledge of their whims, knowledge of their increase. It is often this knowledge which some particular gardener possesses and which should be shared with the general gardening public. I ask every reader to think carefully whether he has not something of interest for all gardeners. If he, or she, has succeeded with a difficult plant, found an improvement in the cultivation or propagation of a particular plant, evolved a new and successful colour scheme, utilised the ground at his disposal in a novel way, and so on, let him—or her—send in a note to THE GARDEN about it.

RUBUS QUINQUEFLORUS

Some time ago I mentioned this most excellent species of raspberry which comes from China. It is certainly one of the best of the white stemmed Rubi, for it is graceful in growth, is not given violently to suckering, has a pretty flower and a most excellent fruit. This is golden in colour and although inclined to be rather tart, has a most pleasant, fresh flavour. An added advantage has just come to my notice. The ordinary raspberry is much affected by damp, and all growers, whether private or commercial, know the deterioration that takes place in the fruit after heavy rain. This is not so with the fruit of Rubus quinqueflorus. Towards the end of last week I raided a large bush of this Chinese raspberry and even after heavy rain found the quality and flavour unimpaired. In its present form it is hardly a raspberry to be grown on a commercial scale, as the crop is not heavy for the size of the plant, but here is, surely, a case for the hybridist? A cross between this and a garden variety might give us perfection in bush fruit. The best plant of this species that I have seen is growing in the open, but is slightly shaded on the west. This specimen is over 8ft. high, with a great central pyramid and numerous canes curling over. Although prickly, the canes are not so thick that one cannot reach the fruit. There is no reason why this raspberry should not grow on a wall.

There are, of course, dozens of Chinese rubi. I have forgotten how many new species Mr. Wilson alone found in Hupeh and Szechuan—and most of them are rapacious frauds, which are best left severely alone, but there are a few exceptions, among them R. bambusarum and R. quinqueflorus. As an economic plant I should imagine that the former was of little use, but the latter has distinct possibilities.

ANDROSACES

WITH THEIR WOOLLY COVERED AND TUFTED LEAVES SITTING TIGHT IN THE CREVICES OF A STEEP ROCKERY AND THEIR DAINTY AND GRACEFUL FLOWERS, THE ROCK JASMINES ARE AMONG THE MOST CHARMING OF THE ALPINES.

MOST rock garden enthusiasts are well acquainted with this beautiful family, either in theory or practice. Androsaces are, however, too often left out of collections owing to their many objections to captivity, and yet, even the most difficult members can be mastered sooner or later by the keenest perseverance, and it is in these instances where the real joy and love of alpines lurk. I recall to memory flowering A. glacialis for the first time. I grew a couple of specimens—in my own opinion, perfectly. They were smothered in dainty, clear pink blossoms, and I was never tired of feasting my eyes upon them. I could see exceptional beauty in them, and considered I was well rewarded for the trouble I had had in keeping them going. I really believe it to be as difficult as Eritrichium nanum. A month from when they were at their best, after a fast decline, both plants were dead, having passed away for no reason whatever. Many other species and varieties are, however, more amiable and of stronger constitution, and can be grown moderately easily, and yet give us the daintiest of flowers. Many are swathed in short silky hair: these are the most liable to succumb to winter wet. Others are shiny and hairless, usually the easiest to manage. A pane of glass over the most tender subjects will often save them, although, if it is possible to do without such means, I should prefer it. A. helvetica is one of the small woolly types, and is one that is often not attempted owing to its minuteness and tendency to become a victim to fogs and rain; but, nevertheless, I know of one particular 3in. cushion that existed unblemished for ten years in an unprotected position in the crevice of a limestone boulder. During those years, the Great War was taking place, so that helvetica had more or less to take care of itself, and this it did to be sure, for up to the present year it was almost as good as ever. Grown as specimens for the alpine house, androsaces are all good and interesting, with much more opportunity to make their name good. I give below a generous selection and description of some of the best of the race:

A. SARMENTOSA, ONE OF THE MOST ROBUST MEMBERS OF THE FAMILY.

ANDROSACE SARMENTOSA.—This is one of the most popular species, being one of the heartiest and most robust growers. It forms a mat of silky rosettes, each from one to two inches across, and these provide abundant pale pink flowers, carried in heads on 3in. or 4in. stems, in May. After flowering, numerous runners are produced, terminating in a fresh rosette of leaves; these lie close to the soil and soon take root with the greatest freedom, after which they may be either left to increase the mat, or be taken away to start a new colony. Treatment is of the simplest, giving it an open, airy position on some well drained gritty soil, preferably on the slope. A sprinkle of pure limestone chips around the collar of the plant will, no doubt, be beneficial to it. From sarmentosa we have the equally pleasing variety known as var. Chumbyi, which differs but very little—chiefly by its flowers being a clear bright rose. Cultural details as for the type hold good.

ANDROSACE STRIGILLOSA.—This is generally the plant that is sold as A. foliosa, with a character and habit quite unlike most of its group. In any good, well drained soil, it presents no difficulty in growing; far from it. It is of a robust thriving habit, making sturdy growth, 6ins. high, with large oval leaves which clothe the stout red stems. In June, we see its large round heads of lilac blossoms on stalks 3ins. or 4ins. high, which arise from within the centre of the cluster the top leaves form. A sunny yet moderately cool aspect will be found to satisfy its requirements.

ANDROSACE LACTEA.—A most delightful, dainty and free-flowering species, best suited for the moraine or scree, particularly limestone, since it is native to the limestone Alps. Granite or other stone chippings mixed with light sandy soil will, however, serve its purpose well. The leaves are long, narrow and sharp-pointed, and are arranged to form a neat, dense rosette. Flowers, large and white, are borne singly at the tips of the slender, many-branching stems, and have a fairly continuous season, commencing when the stems are 2ins. or 3ins. high, until they are 6ins. or even 8ins. During this time innumerable flowers are produced. It sets seed readily, and may be easily increased in that way. Very similar to this plant is the attractive A. lactiflora, the disadvantage of this being that it is only biennial at the most, and very often annual.

ANDROSACE COCCINEA.—Although this plant is more or less biennial, its inclusion among choice alpines should not be despised, as its flowers are of a wonderful scarlet hue seldom seen in alpines, and by saving its seeds a succession of plants may be maintained from time to time. Gritty loam suits it well, and rosettes of a leathern texture are formed, the individual leaves being strap-shaped and coming suddenly to a point. For the hybridist it is a species worth knowing.

ANDROSACE PYRENAICA.—One of the smaller species, covered with the finest of short hairs, and forms compact hummocks of tiny rosettes of wee narrow leaves. It is one of the easiest to do of the small types, and asks for a deep crevice in the face of a rock that may be filled with some sandy and gritty soil. Its flowers are borne, in May or thereabouts, singly, on short stems, and are white and of a starry formation. As the name suggests, the central Pyrenees is its native habitat.

ANDROSACE IMBRICATA requires "growing" to bring it to perfection, as it is not quite so easily established in cultivation and strongly resents excessive moisture in winter. Overhead wet will most likely cause it to die, so we must fall back

Digitized by Google

on artificial protection—provided by tilting a pane of glass over it. It enjoys a hot, sunny aspect, wedged firmly between rocks that do not contain lime, as it is certainly natural on granite in the high Alps. It makes dense cushions of small rosettes of a handsome, silvery whiteness, and snows itself over with large white blossoms which are almost stemless. It would be, no doubt, better suited by alpine house culture, where the conditions can be made more to its liking. Grown in pans, wedged, and slightly raised between chunks of granite in a gritty, well drained mixture would suffice, and water need never hang about its foliage. Little or no water would bring it through our darkest days.

ANDROSACE HELVETICA resembles the two preceding species in habit, having large white stemless flowers sitting on firm downy cushions of miniature green foliage. It is one of the most popular of its section (aretia), and desires a deep sunny crevice in a very porous soil that contains plenty of limestone chips or similar substitute. Its distribution is wide, and it is abundant at high elevations on the limestone cliffs. A. helvetica also makes a good specimen for the alpine house and there it may enjoy a longer life more safely, as too much wet when resting is unwelcome.

ANDROSACE GLACIALIS is undoubtedly a plant for the specialist and for the lover of choice and difficult alpines, as it needs a good deal of care and attention if it is to submit to our cultivation; even then it may—or, at least, usually does—promptly die, so that when one does succeed in making it happy, it is a triumph and a great joy. Although it may bear large and dainty clear rosy blossoms, almost stemless, on cushions of grey-green foliage, its real charm and attractiveness, to me, lie in its culture. Other species are often quite as pretty to look upon and may be far easier to grow. The best place to grow it would be the moraine, where it may be given liberal underground water in the summer and be left as dry in the winter It is calcifuge, and a mixture of sandy vegetable soil with abundant granite chips would be found as suitable as any; or slate chippings may also assist, in view of the fact that it is often found on that material. It has a wide distribution in the European Alps, occurring at high altitudes.

ANDROSACE CYLINDRICA haunts high places in the Pyrenees, but it is not common by any means. It forms mats of stout rosettes of long, broad leaves covered with short hairs; these rosettes usually terminate old stems that are furnished below with the brown dry leaves of years previous. Numerous flowers are produced from the leaf-axils, but are rather starry and not too good a white, unless forms vary considerably, which I have not seen. Too much overhead wet in winter is fatal, so that the necessary precautions should be taken. It desires a sunny, deep and well drained limestone crevice. Similar to this plant are A. pubescens and A. hirtella. Although distinct, they are possessed of hairy leaves and small white flowers, and may be given treatment likewise.

ANDROSACE SPINULIFERA is a quite rare type from China and as uncommon in its mode of life. During the winter, it simply has the appearance of a compact spiny house-leek,

THE DAINTY AND FREE FLOWERING A. LACTEA.

ONE OF THE NEAT COMPACT HUMMOCKS OF A. PYRENAICA.

a tight incurved rosette an inch across, from the centre of which, in spring, it unfolds long oval leaves 3ins. or 4ins. in length, and eventually throws up tall sturdy flower stems with solid heads of deep pink blossoms. A cool position in leaf-mould, loam and sand will suit it well, and it is deserving of a choice position.

F. BARKER.

CONSERVATORY AND GREENHOUSE

SALPIGLOSSIS SINUATA in many beautiful varieties is unique for conservatory decoration, well grown plants attaining a height of 3ft. to 4ft. Compared with other annuals used for this purpose they require a long growing season, and seed should be sown in a cool greenhouse or cold frame from the middle of July up to the beginning of August. In the immediate neighbourhood of London and other large towns where winter light is at a minimum the longer growing season is very essential. This beautiful plant is not one of the easiest to grow successfully in pots. It is advisable to sow the seed in a cool greenhouse. When the seedlings are large enough, they should be pricked off singly into small pots, affording water very carefully and shading from bright sunshine until they are well established. When well rooted they may be given a shift into large sixty-sized pots, in which size they should pass the winter, keeping them well up to the roof glass in a cool, airy greenhouse and giving water very carefully to the roots during this time, as they are apt to suffer from damp. Early in the New Year they should have a shift into 6in. pots, observing the same care in watering until they are well established.

CALCEOLARIAS of the herbaceous section can be sown during July or early in August. A light rich compost may be used for seed sowing. The very fine seed should be carefully distributed over the surface, and it is well to cover with the merest sprinkling of sand. Cover the seed pan with a piece of glass and keep shaded until germination takes place. When fit to handle, the seedlings can be pricked off into pans or shallow boxes, and when they have attained some size they may be potted up into small pots, using a light compost at this early stage. During subsequent pottings use a heavier compost. Calceolarias during all stages of their cultivation should be grown perfectly cool with plenty of atmospheric moisture. During the winter they succeed in low pits or frames that are just kept free from frost. They are very subject to attacks of green fly, which must be prevented by frequent light fumigations. The light and elegant hybrids of Calceolaria cana are so dainty and charming that they are worthy of more general cultivation. As they are available, cuttings should be secured of the shrubby varieties, as represented by CC. Clibrani, Allardii, integrifolia, Burbidgei, angustifolia and alba, young growing shoots of them all being essential for successful propagation. They can all be successfully rooted in a close case in a cool greenhouse.

CYCLAMENS.—Seed is usually sown about the middle of August, but in the immediate neighbourhood of London it is best to sow about a month earlier, for, owing to the lack of winter light, they make very little progress during the winter months. As cyclamen seed is usually very irregular in germination, it should be sown very thinly; this allows for the more forward plants being removed without unduly disturbing the others. The seed pans should be stood in a house with a temperature of 55° to 60°. When large enough to handle, the seedlings should be pricked off into pans or boxes, using at this stage a light rich compost to which some old mortar rubble should be added. The young plants may be wintered in the pans or may be placed singly in thumb pots. In any case they should be kept well up to the roof glass, and should be given water very carefully at the roots, as they are apt to suffer from overwatering during the dull days. Early in the New Year they should be ready for a shift into larger pots. Cyclamens raised from seed last year should now be placed in their flowering pots, which may be 5ins. or 6ins. in size, according to the strength of the plants. The compost should consist of a good medium loam, with the addition of a little leaf-soil and lime rubble, which may with advantage take the place of sand; a 6in. potful of bone-meal may also be added to every bushel of soil. Cyclamens enjoy cool and moist atmospheric conditions, and are best grown in low pits or frames. It is an advantage if the lights can be removed at night, as they derive much benefit from dews.

BULBS FOR FORCING AND GREENHOUSE WORK.—If the best results are to be obtained, freesias, Roman hyacinths and paper white narcissi should be potted up some time during August or at the latest during early September. Thus, if not already done, there should be no delay in placing orders. Ixias in many beautiful varieties should be much more generally grown for greenhouse decoration; also sparaxis, babanias, Allium neapolitanum, Ornithogalum arabicum, as well as the many beautiful varieties of gladioli included in the nanus and ramosus sections. Lachenalias are also very much neglected, and are deserving of more general cultivation; also the beautiful varieties of Tritonia crocata, the variety Orange King being very beautiful and lasting well when cut. The many beautiful species and varieties of bulbous iris are also very charming when grown in pots and pans, being specially useful for the small unheated greenhouse. Veltheimia viridifolia and Bravoa geminiflora are also very useful for the cool greenhouse. There are, however, many other useful and interesting bulbous plants that should be more generally used for the greenhouse, which I hope to deal with in due course.

PELARGONIUMS of the show and regal types that have finished flowering should be stood outdoors in cold frames or at the bottom of a sunny wall. They require very little water at this time, as it is important to get the wood well ripened for the cuttings which should be secured towards the end of August. Pelargoniums of the zonal type that are required for winter flowering should be stood outdoors in a warm, sunny position, as it is very essential that the wood be well ripened before housing them for the winter. In such a position they require strict attention as regards watering and feeding.

HYDRANGEAS.—As they are available, good strong cuttings of the many beautiful varieties of Hydrangea Hortensia should be secured. The cuttings are best inserted singly in small pots. It is not necessary to cut them at a joint, as roots are emitted freely from any part of the stem. They root readily in a close case in an ordinary greenhouse. J. COUTTS.

LUPINS AND DELPHINIUMS

THE name lupinus, derived from lupus, meaning a wolf, was originally given to the plant because it was considered to be a voracious feeder which rapidly depleted the soil of the food stored therein. The wild species of lupin are often found growing on poor sandy soil, where, by means of bacteria which live in little nodules on the roots, they gather nitrogen from the air circulating in the soil, storing it up for the use of future crops. In Germany and, indeed, in many other parts of the Continent, lupins are often sown in poor sandy soils where little else would grow, and are then ploughed or dug in with a view to enriching the land. There is probably no race of plants, with the possible exception of delphiniums, which have been so improved during the last few years, and when it is realised that they are inexpensive to buy, will last for many years, and provide masses of colour ranging from the deeper shades to the softest colours, the demand for them will increase still further. The genus lupin comprises over ninety different species, and while in Europe most of these are annuals, in America, curiously enough, they are mostly perennials.

Among the species well worth growing are the following: Lupinus Hartwegii, a Mexican perennial which is usually grown as an annual in the gardens in this country. During the period between July and October the plant grows to a height of about 2½ft., and bears quantities of beautiful blue flowers with creamy white keels. L. Hartwegii cœlestinus is a lovely variety with pale blue flowers, and the best plan is to sow the seeds in the border during May or early June, thinning the young plants out to 9ins. or 10ins. apart. As soon as they show signs of blooming, any with rose in their colouring should be pulled up, as these are not nearly so attractive as the pure blue flowers.

L. mutabilis, or the changeable-flowered lupin, is a very fragrant half-hardy evergreen plant which, however, is generally treated as a hardy annual. A native of South America, it grows to a height of 3ft. to 5ft., bearing flowers from June to August, varying from white mixed with blue to pink mixed with cream. L. Cruckshanksii, or Mr. Cruckshanks' lupin, was found growing upon the Peruvian Andes near the verge of perpetual snow. It is considered by some authorities to be a variety of L. mutabilis, blooming in July with bluish purple flowers, the centre of which is deep yellow with wings of blue or lilac. This is a remarkably handsome plant, and it was growing to perfection during the summer of 1923 in Mr. P. D. Williams' beautiful garden at Lanarth, near St. Keverne, Cornwall, and later in Mr. Musgrave's garden at Hascombe Place, near Godalming.

Seeds of these annual lupins sown any time during May or the first week of June will bloom in the late summer.

The lupins growing in our gardens are for the most part the progeny of the perennial species, L. polyphyllus, which bears dark blue flowers and is a native of California. There is also a

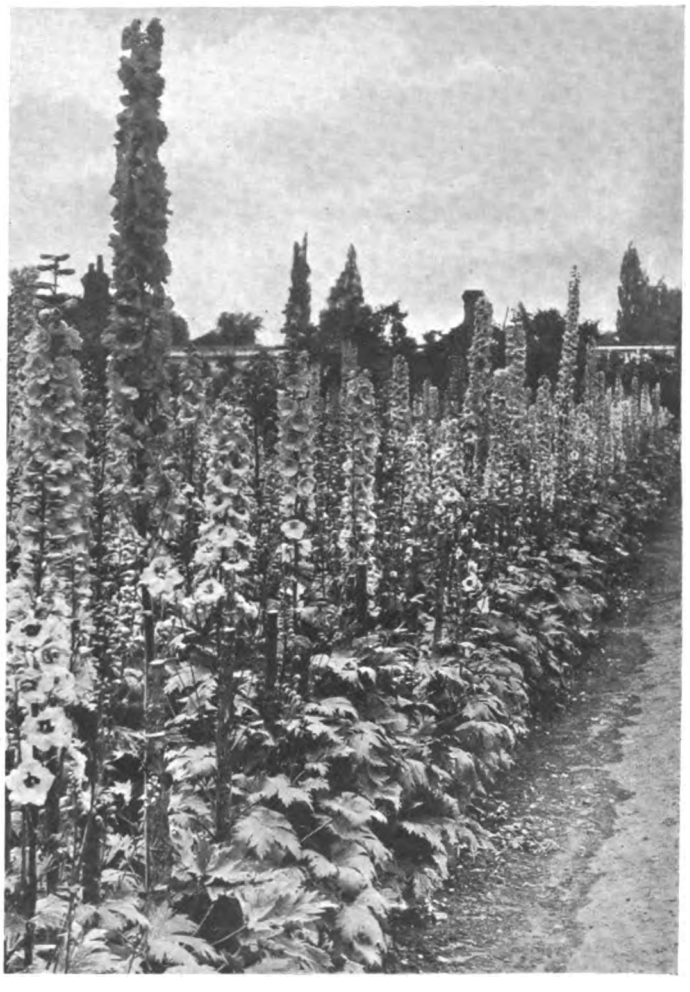
Digitized by Google

A WELL-FLOWERED CLUMP.

white form which is very effective. A new race of lupins introduced during the last few years is the result of crossing this species with L. arboreus, the true tree lupin, which is a native of California, with an evergreen shrubby type of growth. It grows to a height of about 3ft. in California, but in those parts of our country where the climate is at all mild and favourable large bushes are often formed several feet in height. These new hybrids show some of the characteristics of both their parents, are herbaceous in character and die down to the ground each winter. The colouring of many varieties is beautiful, and a border of these flowers forms a picture which is long remembered. The seed may be obtained and sown in the open ground in May, June or July, and the plants moved to their permanent quarters as soon as possible in the autumn. Plants can now be obtained so cheaply, and there is always such an advantage in planting clumps of the same colour, that the purchase of plants is advised whenever possible, and if these are ordered in good time for early autumn or spring delivery, beautiful results will be seen next summer. Individual nurserymen include innumerable varieties in their lists of herbaceous plants, but the following are recommended for any soil and garden: Nellie, which was a cross between L. arboreus and L. polyphyllus roseus, has white flowers tinted rosy mauve. Felicity is rich deep mauve, and a clump of this looks remarkably well at the back of a herbaceous border. Queen of the West is a variety eminently suitable for an amateur's garden, and the young flowers first open a soft yellow, suffused with mauve, and then change in the older flowers to deep wistaria. Milly has flowers of deep lilac, and is certain to be in especial favour where ladies undertake the planning of the garden. The soft pink Cross-Roads, the shell pink Tunic and the salmon pink Mayflower are three of the best pink varieties yet raised. Artist is a delicate blue, while a new variety called Countess of March opens a pure white and then gradually changes to wistaria mauve. May Princess is deep purple, and for those who prefer red shades, Downer's Delight, or its cheaper companion, Fire-Fly, will be successful. The last variety when planted in conjunction with blue delphiniums always looks well. Sunshine remains the best and richest yellow in this section, and the glow of this flower makes it very valuable for effect in the border. In addition to the delightful old species, L. arboreus, with its sweetly fragrant flowers, the new variety Light of Loddon should be included in all gardens. This is one of the best plants raised in recent years.

In most gardens delphiniums may be used to advantage, and these plants have been so improved during the last few years that a few up-to-date varieties should be obtained each year. Nora Ferguson is one of the finest and bears semi-double flowers on long spikes 4ft. in length. The individual flowers are powder blue, flaked or flushed with mauve, and as this variety has a very fibrous type of root, it is especially suitable for use in the average amateur's garden. Some of the single sorts are very lovely, and the sky blue Mrs. Crisp is one of the best. For those who like bright blue, Pannonia can be recommended, while in the deep rich purples an old variety The Alake can still hold its own. Two new varieties, the flowers of which might be described as an exquisite blending of mauve and powder blue, but which are still somewhat expensive, are Mrs. R. W. Ascroft and Peggy Wiseman. For the back of wide herbaceous borders the rosy lavender Shah, with its dark eye, is very handsome and grows to a good height. Where the taller varieties are not suitable, clumps of the belladonna section should be planted, as their branching habit is of especial value for providing spikes of flower for cutting purposes. The very soft blue Musis Sacrum, the dark blue Lamartine and the sky blue Belladonna semi-plena are three of the best.

ROBERT W. ASCROFT.



A HANDSOME BORDER OF DELPHINIUMS

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

NOTES OF THE WEEK

CROCUS ZONATUS.

A VERY delightful autumn-flowering crocus, which can be recommended with every confidence for planting as soon as the bulbs can be purchased, if wanted to bloom this season, is that named Crocus zonatus, so called from the bright yellow bearded throat, which is zone-like in appearance. Its main coloration is composed of rosy lilac, with purple veining, and with a buff tube and the yellow throat already alluded to. The flowers, although small as compared with the great Dutch spring crocuses, are of a good size, and a clump when in flower in September or October is charming near the front of the border or rock garden, while for those who can afford to purchase it by the hundred a free planting in thin grass is lovely at that season. Corms or "bulbs" are not expensive and should, if possible, be planted from the end of July to the middle of August, when they can usually be obtained from bulb dealers, some of whom issue separate lists of such bulbs. A sunny, rather sheltered place in light soil is necessary for C. zonatus, and the proper depth at which to plant is about 2ins.—S. ARNOTT.

ROSEMARY.

THIS hardy evergreen shrub is found in many old-fashioned gardens, and was once held in high favour for its evergreen foliage and fragrance, both of which remain so long after the sprigs are gathered as to be thought almost immutable. Hence Spenser called it "the cheerful rosemarie." It was from its credited ability to strengthen the memory that the plant is said to have been regarded as the symbol of remembrance. More than any other old-time plant it brings with it an atmosphere of mediævalism, and that not merely from Shakespeare's allusion. In Elizabeth's reign was published a song book called "A Handefull of Pleasante Delites" or "A Nosegaie alwaies sweet for lovers to send for tokens of love at New Year's tide or for fairings," and therein was the verse:

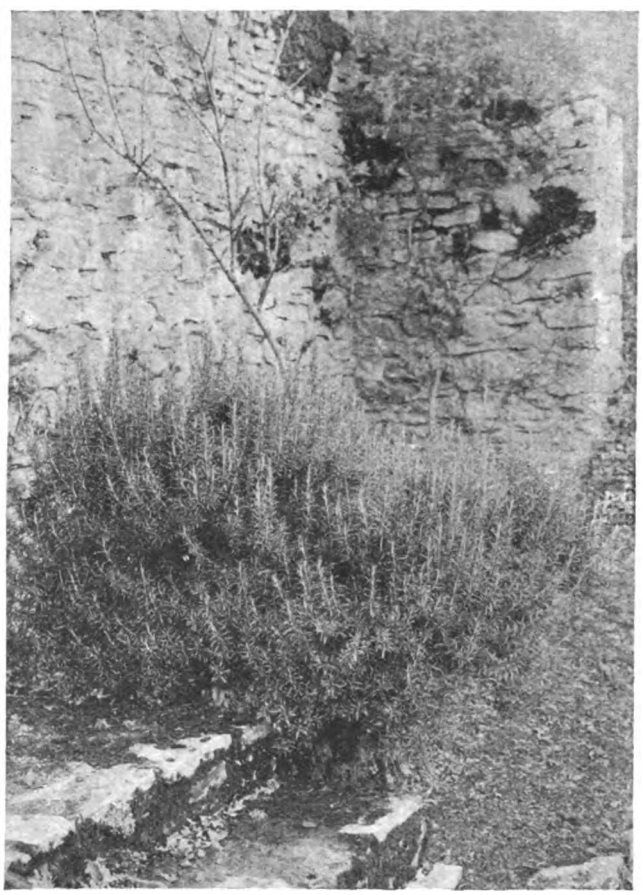
"Rosemarie is for remembrance
Between us daie and nighte,
Wishing that I maie alwaies have
You present in my sighte."

Planted against a wall and left long undisturbed, rosemary will attain a great height and size, with thick, woody stalks from which lutes, carpenters' rules, etc., were once made. The uses of this fragrant herb were many in olden days. It was used to ward off infection, as the chief ingredient in healing lotions and toilet waters for milady's boudoir, to strew on church floors at Christmas-time, and a sprig under a sleeper's pillow was said to induce refreshing repose. At weddings a spray of rosemary, as the emblem of constancy, was placed in the wine of the loving-cup. Contrary to this theory is the still popular idea that where rosemary flourishes the lady of the house reigns supreme. It is symbolical of friendship and remembrance, perhaps because its delicate haunting perfume is unique and must inevitably awaken old associations with pleasant gardens gay with humble blossoms.

The medicinal uses of rosemary are so many that, says an old herbalist, "you might as well be tyred in the reading as I in the writing if I set them down." The plant was once associated with sea spray (hence its name, *Ros marinus*), and flourishes best near the sea coast. It is a native of Mediterranean lands, and the French and Italian peasantry have woven around the plant many charming legends. Like the attributes for which it stands—loyalty, remembrance and friendship—rosemary puts forth its sweetest savour when sheltered from cold winds of neglect. —OSWESTRY.

STERILISATION BY CRESOL.

CRESOL is familiar to all as a black coal-tar disinfectant which when mixed with water gives a white, milk-like emulsion. It is sold under various proprietary names, the concentrate in all cases varying but little from a kind of standard strength; such liquids are in constant use in public halls, lavatories, etc., so that, we venture to say, cresol can be obtained in all towns and villages almost without exception.



ROSEMARY, A FINE OLD-FASHIONED GARDEN SHRUB.

Experiment goes to prove that cresol can be used as a steriliser on vacant land. These experiments were started several years before the war, and by 1914 it was recognised that cresol was useful in that search of ours for something to kill soil pests. Only lately have we ourselves repeated these experiments, and we wish to point out to others the possibilities of the substance.

Cresol used at a dilution of one dessertspoonful per gallon of water kills cabbage maggot, carrot maggot, white grubs, leatherjackets, wireworms and other soil pests. Actual contact, even, is not required, the carbolic fumes being deadly enough if near the pest; but every effort must be made to impregnate the ground, to moisten it to a depth of some 6ins. This is most easily done at digging; no other action is required—simply wet the soil. Cresol must not be used where there are plants. We find that certain plants and shrubs will survive the ordeal when dormant, as in winter, but no hard and fast rule can be determined, hence the above advice. A taint of it in winter-wash liquors—five times the above dilution—does no harm to dormant fruit trees and is decidedly a deterrent to bird pests. Turf treated with cresol is wireworm-free. These are a few other uses.

Soil or land must not come into immediate use after cresol is employed. The period which may elapse varies greatly, according to the weather mostly, but a safe period is a month; warm weather frees the ground much quicker than any other of our special weather samples, but yet an application in warm dry weather is more effective than any other application.—LANARKSHIRE.

MIMULUS BARTONIANUS.

FOR growing in cool and perhaps slightly moist positions the various forms of mimulus are ideal subjects, and the plant under notice is quite distinct from the majority. It was raised by Mr. H. O. Barton of Co. Antrim, and the parentage is stated to be M. Lewisii and M. cardinalis. The foliage is dark green, and the flowers, some 2ins. across, are bright rosy cerise with a yellow throat. It began to bloom early in June, and, at the time of writing the plants are a mass of flower, such a state of affairs will continue until early autumn, when the plant gradually dies down. A stock can be raised by means of cuttings in August and September, and they should occupy a cold frame for the winter.

I think this plant is fairly hardy, but last winter several examples were lost, perhaps owing to the sodden condition of the ground when the roots were dormant. However, it is very attractive and distinct and is worthy of a trial. —T. W. B.

NOTES FROM READING.

THERE are two dianthuses with yellow flowers out now. One has its pistil blue, the other white. This is the only difference I can see. One is labelled "aridus" the other "Knappii." Can anyone tell me the name of a dianthus with white flowers, very much fringed, with the scent of a Daphne Cneorum, though weaker, and foliage as prickly as Acantholimon venustum? Dianthus Donizetti is a fine colour and seeds abundantly. D. Forrestii seems to be a hybrid with barbatus blood in it. The colour is most attractive. A tree of Magnolia salicifolia 15ft. high flowered fairly in March, but now is covered with blooms for two-thirds of its height. Catalpa bignonioides 25ft. high and 30ft. through has been a marvel of beauty. Its flower clusters are finer than those of the horse chestnut and are deliciously scented. The leaves are particularly soft and velvety. Why such a treasure is so comparatively rare is a mystery. The tree is extremely shapely and gives a most grateful shade in hot weather. Eucryphia pinnatifolia, also 15ft. high, is covered with its white blossoms, to which the stamens lend an additional charm. Thalictrum dipterocarpum, showing its head above the dwarf shrubs among which it is growing, is singularly graceful. Of gentians, Lagodechiana, Freyniana and Purdomi are the best here.

Digitized by Google

There are many of the type of cruciata all much alike but with many different names all hailing from various botanic gardens, but none corresponding to the prints of them in the *Botanical Magazine*. Omphalodes Luciliæ, which used to be the show plant of the garden, is once more looking happy and is covered with bloom. In a shady corner there are growing happily together Wahlenbergia hederacea, Linnæa borealis, Epigæa repens, Shortia galacifolia, Mitraria coccinea, Philesia buxifolia, Gentiana pyrenaica, Sisyrinchium filifolium, Pyrola rotundifolia. In a hot border, which has a glass over it in winter, there are in flower now Diplarrhena Moræa, Cypella Herbertii, Hippeastrum brachyandrum, Gerbera Jamesoni, Dianella cœrulea, Alstrœmeria hæmantha rosea and A. pelegrina. Pasithea cœrulea and Pentstemon puniceus are just over. P. cordifolius is just beginning to flower. Anemonopsis macrophylla and Deinanthe cœrulea are at their best, growing in a shady peat border. Gaultheria trichophylla has yielded a good crop of its blue berries, and we are collecting the yellow fruits of Leucopogon Fraseri. Polemonium confertum is flowering for the second time. The donor finds it an easy doer which rapidly increases in size and admits of division. We envy him, but are most thankful to have the plant again. The variety mellitum seems equally scarce. Polygala calcarea is still in full flower. On the Berkshire downs it covers many square yards, growing close to one of the patches of Anemone Pulsatilla. A generous friend gave me a splendid plant of Campanula Zoysii in full bloom. For half a day it was the glory of the garden, then slugs or snails endowed with some uncanny sense found it and left but a remnant. Paliurus Spina-Christi always flowers in profusion but never sets seeds. We have only one plant. Let no one who has a microscope deny himself the pleasure of discovering the beauty of Garidella Nigellastrum.

I have left to the last by far the most lovely occupant seen in the garden lately, a baby goldfinch, which allowed the gardener to pick it up in his hands and stroke its back. It seemed to like his attentions, though it would not drink the water or eat the worm he offered it, but it spread its beautiful wings and showed the wonderful gold of its under feathers. He placed it on a cherry tree, and from there it flew some 10yds. and then alighted on the lawn, revelling in the hot sun. He took it up again in his hands and put it on a soft cushion of a saxifrage on the rockery and left it there, and we have seen it no more. There are no cats in the garden.—A. C. BARTHOLOMEW.

THE HERBACEOUS PEONY IN CANADA.

ONE evening early in July the telephone rang, and taking down the receiver I was told that Montreal was speaking. I listened, and the familiar voice of a friend said: "My peonies are in blossom, will you not come up on to-morrow night's train and see them?" Except that I love all flowers, I have no particular penchant for peonies, but I have heard something about the peony in Canada and decided that this was a good chance to check up the story by personal observation.

I went, I saw, I returned amazed, charmed, enraptured. Canada can grow peonies unsurpassed the world over. I saw all the standard varieties of France, England and America flaunting their blossoms perfect in colour and form in I know not how many tens of thousands. I saw more than twenty thousand blooms of the superb Marie Lemoine, queen of all white-flowered peonies. From these fields some ten thousand blossoms had been cut and, through the patriotic philanthropy of far-sighted men, sent to England to be placed on exhibition at Wembley. If these travelled well the experiment would give English friends a glimpse of what daughter Canada can do in the growing of flowers. And the peony is not the only flower that flourishes to perfection in Canada. Far from it. But the peony has peculiar merits of immense value to Canadian gardens. The foliage is dark, lustrous and telling in effect, even after the flowers are past. In the winter the stems die down and the plant lies snug beneath the snowy mantle that covers the ground.

In Canada, for planting in city parks, edge of lawns, and in plats that abut on the street, the peony is perfect. A shrub of any sort would be injured, if not ruined, by the snow-plough passing over it or dumping snow on top, in fact there are laws forbidding the planting of shrubs in such places. The peony, which throughout the spring, summer and autumn has all the good qualities of a fine shrub, disappears completely in winter and offers no obstruction in the clearing of city streets and side walks.

Christened "Lady of the Snows" by Kipling, Canada right worthily is the "Land of the Peony Rose."—E. H. WILSON, *Arnold Arboretum*.

PLANTS IN NORTHERN AFRICA.

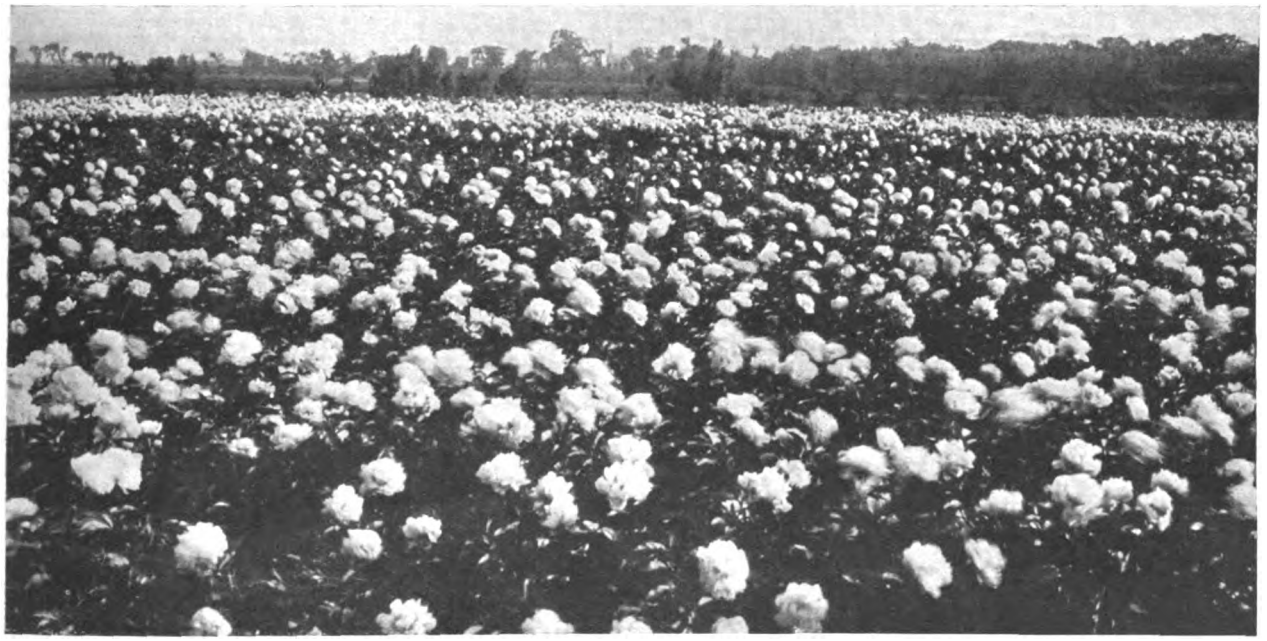
OUR first expedition to find plants in North Africa was to the plateau of Ras Afour, near Maruia, on the borders of Algeria and Morocco. One of our objects was to find the hybrid between Quercus Mirbeckii and Q. Ilex, which we were told was there, but we did not find it. We saw great forests of scrub evergreen oak and at the top of the plateau some picturesque veterans of former great forests, but no good trees and only this evergreen oak. The plateau is 5,000ft. high and had lately been covered with snow. In fact, we still found a patch of snow in a hollow, though the day was very hot.

Our disappointment in not finding the trees we wanted was made up for by seeing sheets of a lovely salmon coloured asphodel (Asphodelus repens, *Pouret*), growing flat on the stony calcareous soil, as if thousands of large asphodel flowers of a brilliant pink had been stuck in bunches among the stones. This gem has the most delicious perfume. All day we got whiffs of it as we hunted for other things among the dwarf oaks. I think, too, it should be hardy in England, as the winters at that height are long and very cold, but they get a tremendous ripening in summer.

On rocks in the shade we found a white form of Narcissus bulbocodium (Corbularia monophylla); this was growing in leaf-mould in crannies of the calcareous rocks. Quite close to it, but more in the open, Crocus atlanticus still had some of its lavender flowers, though it had nearly finished flowering.

On the way down, by the side of the road, in the hardest soil and schist rock, there were quantities of Tulipa celsiana, delicate yellow flowers flushed with a reddish-brown on the outside.

The whole of the slopes of the hills below the plateau are covered with a scrub, largely composed of rosemary, Calrycoton intermedia, looking very like gorse in bloom, and smelling like it, too; Cistus ladaniferus, with the large crimson blotch on its petals, and the small, but delightful, C. Clusii neat little



A FIELD OF WAVING WHITE PLUMES OF PEONY MARIE LEMOINE.

Digitized by Google

green bushes covered with white helianthemum-like flowers. Here and there was a fine form of Lavendula Stœchas, very compact and grey, with large light purple bracts, a really decorative plant.—LAWRENCE JOHNSTON.

SATAN S SNUFF BOX.

ON an autumn morning, it is not uncommon for a gardener to find a lawn dotted with small, white, roundish, tuber-like plants, or puff-balls, although none of them was visible disfiguring the grass-plot on the previous day. The larger kinds are more seen during the autumn, growing in orchards near the roots of fruit trees, or in fields, being sometimes several feet in circumference. But in our country, rustics are apt to look upon all fungi which are not mushrooms as poisonous "toadstools," and, therefore, if they come across these monstrous puff-balls, often demolish them by crushing them under their feet. It is a pity, as they are perfectly innocuous when either handled or eaten.

These giant puff-balls, as they have been very properly designated, can hardly fail to be of some interest to any person who has the time and opportunity of studying closely plant life, as they are wont to exhibit an amazing rapidity of growth. Indeed, Carpenter, in his "Vegetable Physiology," goes so far as to say that "A large fungus of the puff-ball tribe has been seen to grow in one night from a minute speck to the size of a large gourd. No other living beings have powers of growth at all to be compared to this." Such prodigious increase in size in so small a time may well remind us of the description given in Scripture of the gourd which came up in a night and shaded Jonah.

Before any fungus of this kind becomes over-ripe its outer covering or rind looks like white kid, and the pulp inside, if examined, is found to be of a creamy whiteness and firm and fleshy. It is then very nice to eat if it is rightly cooked, tasting not unlike sweetbread. No one need fear to partake of it freely, for its size and globular shape make it impossible to mistake it for anything else. After having removed its outer skin, slices of the pulp about ½in. thick can be fried in butter and each slice may then be dipped in a beaten-up egg and sprinkled with breadcrumbs. Although there is a prejudice at home against puff-balls, yet in some countries they are commonly eaten, and one of the giant species is enough to satisfy the appetites of ten persons. When over-ripe

A GIANT PUFF-BALL.

the pulp is of a brownish colour and becomes dry and powdery, the powder consisting of spores interspersed with many fine filaments. Eventually the rind bursts and the spores, somewhat resembling grains of snuff, are emitted in the form of smoke. In former times there were among the peasantry some who employed the powdery portion of the fungus as a remedy for stopping bleeding. Not long ago an old countrywoman in Kent related that when she was a girl and bled from the nose her mother took her to an orchard and, picking up from the ground a puff-ball, applied the powder from it to her nose with good effect. As regards the use of the fungus in surgery, there is good evidence that it has been applied by surgeons for centuries to arrest bleeding, with excellent results. Its spores have been dusted over bleeding surfaces, or pieces of its pulp plugged into deep bleeding wounds where the cut blood-vessels could not be reached to be ligatured. As the pulp is very soft and porous or spongiform, it makes an exceedingly comfortable surgical dressing, and wounds often heal under its application without the formation of a scar. But it ought, before being applied, to be heated in an oven, to kill any noxious germs it might harbour. Bee-keepers, now and again, when they wish to procure the produce of a hive without destroying the lives of the inmates, ignite the puff-balls and then expose the bees to the fumes which arise and have a stupefying effect upon the insects. Also, this method of quieting bees has been adopted in order to introduce alien bees. But it has the disadvantage of leaving a disagreeable odour, which hangs about the stock for some time and is much more troublesome and less effective than chloroform. Furthermore, veterinary surgeons have by means of such fumes been able to produce insensibility to pain in dogs requiring operative treatment.

Among the majority of the commonality there appears to be a strong feeling of loathing and contempt in respect to this particular fungus. In fact, in some parts of England it is popularly styled "Satan's snuff-box," and in Scotland the "de'il's sneeshin'-mill" (devil's snuff-box). But it ill deserves to have such opprobrious epithets applied to it, as I have endeavoured to show.

It is a valuable article of diet, possesses powerful styptic properties, and is a useful agent for narcotising certain animals.—E. K., *Gravesend*.

NOTES ON STRAWBERRY CULTURE in the OPEN

OF all the so-termed "soft fruits," probably the strawberry is the most highly esteemed by all classes, rich and poor alike. In this article I will confine my notes to the cultivation of the strawberry for garden purposes, such as I have practised on successful lines for a number of years past. As a dessert fruit, the strawberry is in great demand as long as it is procurable; while for preserving, it is one of the most important of all fruits for the winter supply. This being a recognised fact, strawberries should be more extensively and better cultivated than they have been during the past few years.

No better time than the present can be selected to prepare for next season's supply, and any means of prolonging the supply of fruits, either by hastening or retarding, will, I have no doubt, be welcomed by your numerous readers. In many gardens, strawberries are grown in one position only, whereas by planting in various positions the season's supply may be extended by several weeks; in fact, nearly double the usual period. This is especially so in a season of heat and drought, like the present, providing the proper varieties and positions are chosen. The earliest fruits are always produced from strong, sturdy, well grown plants.

Now is the time to secure runners, from plants put out last season, as these young plants always give the best and strongest runners. Prepare a sufficient number of the different varieties required, retaining several of the best on each parent plant. The first runner produced on the stolons being invariably the best. All the others should be removed, together with weeds that have accumulated during the fruiting period.

Clean a sufficient number of large 60-pots, place one crock in the bottom, fill moderately firmly with a well mixed compost of 3 parts loam, 1 part old mushroom-bed manure (or, failing that, decayed leaf-soil passed through a ½in. sieve) and a slight dusting of old soot and fine bone-meal. See that the soil is in a moist condition for use.

Place the pots on the strawberry bed, in blocks together as much as possible, as this considerably helps forward the work both in the layering and daily sprinkling with a fine rose can; then place one strong runner in the centre of each pot.

I have found it advantageous to place small stones on the runners, in preference to pegs, to keep them in position till rooted. The stones conserve the moisture and assist in the formation of roots. Any of the short straw left on the beds may be placed round the layering pots, to prevent undue drying of the soil. Daily sprinklings must be given, preferably in the evenings, until the runners are established in the pots, any runners that are formed being immediately removed, thereby conserving the strength of the layers in the pots. Should the weather prove very dry, a good watering of the parent plants may be given, and help to keep down red spider, one of the worst enemies of the strawberry. During the time the plants are rooting in small pots, the various positions the plants are to occupy in their fruiting quarters should be prepared.

For the earliest supply, an open situation on a south border (say, 100ft. in length, or more, according to requirements) should be prepared and a liberal quantity of well decayed manure worked in. The following plan I have adopted for some years with success: After the preparation of the soil and lightly treading

Digitized by Google

over and raking, the strongest plants are set out 14ins. apart all ways, placing them alternately. One point of vital importance when planting out strawberries is always to place the crowns facing south: also plant out the young stock as early in the season as possible, and before the plants become root-bound in the pots. By early planting and due attention to watering, etc., the plants start growing at once, and become well established in their new quarters, building up firm crowns—so essential to early fruiting—before the winter.

Returning to the south border plots. Half of these plants (100ft. run) are protected with lights during the winter and spring months, resting on a low skeleton frame made with odd pieces of quartering and boards.

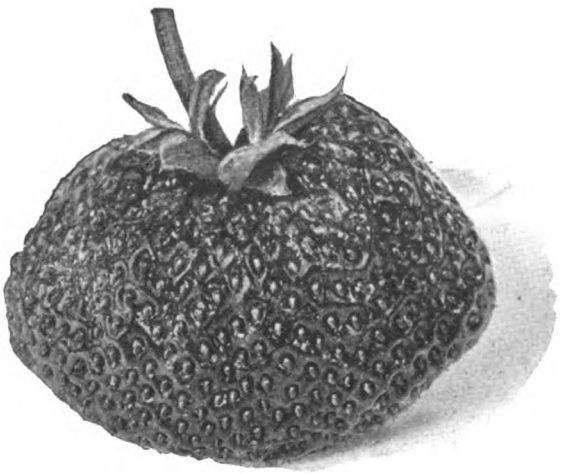
Strawberries thus protected may be advanced several weeks. The others on the south border, not so protected, form a good succession. The varieties Royal Sovereign and The Duke will be found the best for this purpose. Use the hoe frequently, removing all runners as they appear. In the early spring, apply a sprinkling of lime and old soot, to keep down slugs; and, before placing short straw among the plants, apply a dressing of artificial manure. These early plants will well repay the extra attention given. Plenty of ventilation must be given during the flowering period, and a pampas plume may be used to fertilise the flowers. As soon as the blossoms fade, a good watering with tepid water may be given: in fact, cold water should never be used with these first early plants.

Support the fruits with small pieces of birch: those from old brooms are suitable. Close the lights fairly early in the day, well syringing the plants, until the fruits commence to colour, when syringing should cease and more air be admitted. Nets must be put on early, as birds are particularly troublesome with early fruits. Even in the frames a net must be thrown over the lights: it being necessary to have a considerable amount of air admitted as the fruits ripen, otherwise the flavour is impaired.

Having thus arranged for the early supply, the next, and more important, is the main crop, and for this one of the best positions, fully in the open, where full sun and air may reach the plants, should be chosen. The ground should be deeply dug and liberally manured, sufficient to carry the crop for two seasons. I consider the best results are obtained by keeping the plants two years only, as a third crop often results in a great number of small berries. For this main crop, the plan I adopt is as follows: After the ground has been thoroughly prepared, lightly trodden and raked over, the plants are set out in lines 30ins. apart and 12ins. from plant to plant. Always plant with the crowns facing south, as advised before. Attention must be given, with watering, hoeing, and the removal of any runners that may be formed, as recommended for the early crop. Plants thus treated will give a good crop of fine fruits next season. After the first season's fruiting, and as soon as a sufficient stock of new layers have again been secured, all the alternate plants are cut out, finally leaving them all at 2ft. apart between the plants. The two-year old plants will then have room to develop and fill out the alloted space. It will at once be seen that, by close planting the first season, a full crop of fine fruit is secured.

Space should always be available for continuing this strawberry bed for the next season, so as to keep the main crop under one netting. A piece of ground may be cropped with early potatoes or peas, and thus be available in time for the planting of strawberries at the end of August or early in September.

The after-treatment of strawberries consists of removing promptly all runners and a considerable amount of the old foliage, together with all weeds and mulching; these should be burned. If the season has been dry, hoe the soil and give a thorough watering at the roots, to enable the plants to put forth new foliage and build up crowns before the winter months. A good dressing of decayed manure should be placed among the plants and lightly pointed in with a fork. Strawberries should never be dug between with a spade, and only lightly with the fork. Some time early in March the beds should be again gone over, and any vacancies that occur made good. Gaps in strawberry beds are always an eyesore. A small handful of bone-meal at this time (March), lightly pointed in, and, later, a dressing of old soot when the flower spikes are visible, will help the old plants considerably; or a dressing of some approved artificial manure may be applied before strawing down the plants for the next crop.



REARGUARD, A LATE-FRUITING VARIETY.

A word regarding the netting of these main-crop strawberries may not be out of place, as birds play havoc with the fruits if not properly netted.

Good strong posts, at the corners and at intervals in the lines between, are desirable. Oak posts, 3ins. square and standing 3ft. out of the ground, are excellent to carry the straining wires over the bed, using smaller stakes at intervals in line, thus dividing the bed into a series of squares when the wires are fixed, whereon the net rests throughout the season. Once the net is properly fixed there is no further trouble, ample room being secured to move freely under the net, and, to a certain extent, bird-proof. Half-inch wire netting should be employed, 18ins. deep all round the ground-line, and securely pegged down; on to this the net is secured, one place at the corner being used for going on and off to gather the fruits. Both net and posts last for a number of years if properly kept for this purpose. The vareties of strawberries are manifold for main crops, but such standard sorts as Laxton's Leader, Reward, Royal Sovereign, Utility, Bedford Champion, The Duke and Givon's Late Prolific may be relied upon, having stood the test of time. A few rows of that good old strawberry, Vicomtesse Hericart de Thury, should be included for preserving purposes; it is very firm and sweet, consequently most of the fruits preserve whole, and for this reason it is esteemed by many. It is an abundant cropper.

Having dwelt at considerable length on the main crop—which is, of course, the most important, a few remarks on the late sorts, thereby extending the season's supply, may be opportune.

LATE VARIETIES.

As already mentioned, strawberries are always appreciated so long as they are obtainable in good condition.

By reserving a goodly portion of the north border, and planting late varieties, the season may be considerably prolonged.

The ground should be well manured and prepared, as previously advised for other beds.

It will be noted that many of these late varieties are not of such a vigorous habit of growth. Consequently, they may be planted in rows 2ft. apart, allowing 1ft. between the plants, for the first season, removing alternate plants afterwards, as already described, eventually leaving all at 2ft. The varieties for late fruiting may include Waterloo, Trafalgar (two excellent strawberries, dissimilar in colour and ripening at the same time—a valuable addition for dessert), Givon's Late Prolific (another fine strawberry), Laxton's Latest and the newer Laxton's Rearguard. From these late strawberries fruits may be gathered for several weeks after others are over.

Should the weather prove at all unfavourable, lights may be placed over the fruits on inverted pots, nets being used over the lights as for the early supply.

I have found strawberries grown on the north border to fruit well for three seasons, growth being less rampant in such varieties and position.

Having thus described the various ways of prolonging the strawberry season, I venture a few further remarks.

It is an open question whether strawberries are cultivated as well now as in former years.

Certainly, as regards quantities for market they have undoubtedly increased. But from a private point of view, I do not think they are so well grown. One of the great drawbacks to the successful

Digitized by Google

cultivation undoubtedly is the great difficulty in obtaining manure—good stable manure. Whereas in times past abundant supplies could be had from the stables, now very little, or none at all, can be had, as motors have taken the place of horses. Again, the high price, when the manure can be obtained, prohibits the liberal use of it, as gardeners would like to use it. Another cause is the shortage of labour in many gardens; the time cannot be spared for everything as in years past. To grow strawberries well, they require plenty of manure, and will pay for it in the long run.

I well remember growing that fine old strawberry, Laxton's Reward, plenty of fruits seven to eight to the pound, brilliant crimson in colour, and of fine flavour. It seems a pity some of these sorts go out of cultivation.

Strawberries, after being grown in the same garden for a number of years, deteriorate, much the same as do potatoes. Hence the necessity of obtaining fresh stock occasionally. Most of our nurserymen raise plants for sale annually, notably Messrs. Laxton Brothers, strawberry specialists, who have raised most of our new varieties, as well as the old favourites.

The present is a most suitable time to secure plants, and no better time than the present to make plantations for next season's fruiting, either by purchased or home-raised plants. I. HAWKES.

CORRESPONDENCE

FORTUNE'S YELLOW ROSE.

SIR,—From the description of the climbing rose on the Italian lakes, and its fragrance, I am pretty sure that the rose "M. L." saw there last spring is Fortune's Yellow—"Jaune de Fortune" as they call it on the Riviera. It succeeds well in southern England, but it needs *moisture* and shelter; hence its vigour and beauty on Lake Como.—E. H. W.

GLASSHOUSES.

SIR,—In the very interesting editorial leader of THE GARDEN of July 11th, every line contains matter for thought on the part of those who possess glasshouses. But I would like permission to refer to one only of the many points, namely, "the uses to which the glasshouse will be put during the coming season." One of my four glasshouses is unheated, and perhaps it may be helpful to others if I briefly state how I use it during the whole year. My year's treatment begins in November by planting stocks, Beauty of Nice and Empress Elizabeth respectively, in the side borders next to the walls, which are low. The remaining parts of the structure are filled with chrysanthemums in pots and lifted from the outside borders. In January the borders are sown with radishes, French breakfast varieties, and on both sides of the central path sweet peas are planted. Two crops of radishes are raised before their place is occupied by tomatoes, and in the meantime the stocks are yielding their fragrant flowers for cutting purposes. The sweet peas are cleared out at the end of June, also the stocks, and two rows of late tomatoes take the place of the stocks. In October the chrysanthemums are again brought in. At both ends of this span-roofed glasshouse roses are grown, being planted in the borders, pruned in late autumn, and yield pink, white and crimson blooms from early May to autumn—four lots altogether. This has been my plan with the unheated house during the past ten years. At a very small cost it has yielded a lot of valuable produce. Others may do similarly.—G. G.

PRONUNCIATION OF BOTANICAL LATIN.

SIR,—The following remarks may assist your correspondent F. C. King and any others who may experience the same difficulty. Pronounce long Latin vowels thus: e as a in *pl*a*te*, and a, i, o and u as in *f*a*ther*, *mach*i*ne*, *st*o*ke* and *r*u*le*; y as ui in *g*ui*d* (Scots), æ as i in *r*i*de*, and œ as oi in *v*oi*ce*. Short Latin vowels are pronounced much in the same way as long ones, but less broadly. If this is too difficult an exercise in phonetics, pronounce them as in the English *f*a*n*, *d*e*sk*, *s*i*ng*, *h*o*t* and *b*u*tcher*. Latin consonants are as in English except j and v, which pronounce as y in *y*ou and w in *w*in; c and ch are always as English k; g and s always as in *g*et and *s*end. The foregoing rules apply to pure Latin, but much of botanical Latin, so called, consists of modern surnames and place names with -ia, -ense, etc., tacked on to the end. It really does not matter much how these names are pronounced; the construction of most of them is so hopelessly bad that no conceivable method of pronouncing them would be correct. They should never have been coined at all, and the best thing to do with them is to leave them alone as far as possible, use the equivalent English name whenever there is one, and invent one when there is not; but if they must be tackled, the most usual way of pronouncing all the important ones will be found in Webster's New International Dictionary, which can be consulted at some convenient free library. In specific names commencing with a capital letter and ending with two i's, the second i may be omitted in speaking, and for that matter in writing as well; it is redundant, and its presence is due chiefly to a red tape regulation made by some conference or other. In ordinary conversation, when referring to a generic name by itself, the usual rules of Latin are often not followed; thus of the two instances mentioned by your correspondent cyclamen would in such circumstances be pronounced siklamen. It is to be observed, too, that some botanical names are Greek, not Latin.

The foregoing comments do not touch on the accentuation of pure Latin, that is, which syllables ought to be stressed and whether the vowels are long or short; this cannot be dealt with briefly, but the information can be found in the case of any particular word on referring to an ordinary Latin dictionary, one or more of which will be available at the nearest town (public) library. More could be added, but I will not trespass further upon your space.—H. A. BAYNE.

ROSE ARTHUR COOK.

SIR,—Can any of your readers who are experts on roses give me their opinion of the Rose Arthur Cook, and whether their experience is the same as mine?

I have four plants of this rose. On some the bloom comes perfectly true, a rich crimson, others on the same plant come with pink petals, and one almost a pink rose. In my rose house this difference did not appear, but I should be glad to know whether growers find that it has this habit. The blossom which came out pink was of a lumpy shape, and it had no characteristics of the rose as described. —LADY ARDILAUN, *Dublin*.

FEIJOA SELLOWIANA.

SIR,—This flowering shrub has done extraordinarily well this year and is a mass of bloom; it seems quite hardy. When at Messrs. Veitch's gardens in Exeter last week, the foreman complained of their plant not flowering. On seeing it, I found it was between two glasshouses in the shade, and there is no doubt it requires to be in full sun. A few years ago it fruited with me.—H. G. HAWKER, *Devon*.

OLEARIAS.

SIR,—I venture to add a word to Sir Herbert Maxwell's very interesting article on Olearias.

Yes, O. semidentata is certainly a very desirable shrub. I find that it stands a great deal of wind, as does chathamica; and its grey-green and silver leaves are of rare beauty, even if it were never hung, as it was recently, with its pale lilac, dark-centred daisy flowers. I put this very high among flowering shrubs for wild gardens.

There is a hybrid between O. stellulata and O. lineata which is a finer plant even than the type: the flowers are more striking and the plant is less liable to look ragged after flowering or after bad weather. It makes a larger bush than stellulata.

O. lacunosa is growing now in a few Cornish gardens. It appears to need shade. There is a delightful picture of a full grown bush of it in Dr. Cockayne's small book on the New Zealand flora.

O. ramulosa is a beautiful little creature, covered with small white stars; and O. Solandri, like virgata, is a good seaside plant.

Sir H. Maxwell has little use for O. Traversii, as its flowers are very uninteresting: but as a quick-growing shelter plant it has, I think, a very high value. It is a beautiful grey-green evergreen, always healthy-looking and trim, and flashes brilliantly white in the wind. It grows marvellously fast, making a tall hedge in three years from cuttings even in the poorest wind-swept spot. I have found very few plants so good for a windy exposure, especially if it is pruned down a bit till well established. I hear that they have an equally good opinion of it at Scarborough, where it is being planted extensively for shelter.

The one other olearia I want to refer to is O. oleifolia. The late Mr. T. Smith of Newry, that great expert, considered this, I believe, one of the best shrubs of recent introduction for windy seaside gardens; and its behaviour here seems fully to justify this. It makes a solid, well furnished evergreen, covered with white flowers in autumn, and thrives in the fiercest sea wind. I have planted it with O. Traversii and O. albida on a rocky bluff 600ft. over the Atlantic, with no shelter whatever, and it continues to thrive unscorched and undistorted.—W. ARNOLD-FORSTER, *Cornwall*.

FAILURE OF GYPSOPHILA.

SIR,—Under the heading "Failure of Gypsophila" a contributor in your issue of August 1st suggests the use of superphosphate for correcting a deficiency of lime in the soil. But superphosphate cannot fail to *reduce* the quantity of available lime. I have used it successfully for that very purpose in converting a somewhat chalky soil into a lime-free medium for the culture of ericaceous plants. The excess of phosphoric acid implied in the prefix "super" is responsible for the lime-reducing effect.—MICHAEL CHAMPNEYS, *Suffolk*.

SIMPLE GARDENING

LAYERING BORDER CARNATIONS.

As the weather was very hot and dry for some time just before Midsummer Day and again for a time soon after, the work of layering border carnations was delayed in many parts, the soil being too dry and the wood of the plants rather hard. Layers should be rooted as early as possible, so that the young rooted plants can be planted in their flowering quarters early in the autumn to ensure a safe passage through the winter. But to those who love these flowers I would like to say, make preparations now for the layering of as many plants as possible in a short time and give them careful attention afterwards. During very hot weather I like to use more, rather than less, of the heavier part—loam—of the compost in proportion; and later in the season, more sand and leaf-soil, so that the compost will not retain moisture too much if a spell of rainy weather comes. The compost should remain sweet if new roots are to enter it freely. Carefully examine the parent plants and remove all foreign matter found under them and all faded leaves. Having mixed the compost, as suggested, be liberal when packing it around the old plants, so that the layers will have plenty of body to root into. Each layer should be denuded of its basal leaves, and cut, slant-wise, from the underside upwards and half way through the stem with a sharp knife. Place a tiny stone in the cut stem, bury that portion of it in the new soil, peg down and water when necessary till roots are formed.

HARDY BORDER FLOWERS.

The past summer weather has been very trying for all open border plants, except in soils low-lying and naturally moist. I know one garden where the tidal waters come near to it in open dykes and, about 3ft. below the surface one can always find water, however dry the season may be. The owner of this garden can always grow extra fine herbaceous plants in dry summers and has no difficulty in keeping the borders bright and in a neat condition. This is not the case where borders are high and naturally dry; such borders require much more attention throughout the season: it is necessary to clean the plants often and to remove the faded leaves and flowers; more water is needed and also good mulches to prevent undue evaporation from the soil. At the present time owners of such gardens should put them in good order. Do not remove any more green leaves and stems than absolutely necessary, because such action would weaken the plants. Some cultivators, in order that they may have very neat borders, cut down too much foliage. The stems, of course, die at the end of the season, but they should be allowed to fade as naturally as possible, then the roots and young crowns which are to bear next years' crops of flowers will be duly strengthened, not weakened, as is the case when the plants are slaughtered at this time of the year. Make notes now about future alterations and renew defaced labels.

"TAKING" CHRYSANTHEMUM BUDS.

There are still many lovers of the big blooms, those large, but refined and richly coloured. It is only by timely disbudding that one can secure the big blooms and by taking the right buds according to the varieties. Some, such as Mrs. Gilbert Drabble, William Rigby and Queen Mary, Majestic and Victory, must be disbudded during the latter part of July; the majority of the varieties grown should have their buds taken about August 10th to 20th, a few, such as Mrs. George Monro, Junr., bear the best blooms when their buds are taken late in August. I have seen fine blooms

resultant from buds taken late in September, but this is an exception and the happy medium is the best. Very early buds of naturally early sorts develop into coarse, badly-coloured blooms. Crown buds are dealt with first; they are the ones which are surrounded by young shoots as shown at *a* and *b* respectively. At *c*, lower down the stem, side shoots have been pinched out on earlier dates. If the crown bud *a* is removed and the side shoots grown on, we have terminal buds; *d* is the terminal to retain and side ones *e*, *e*, the ones to remove. Tiny grubs spoil many points of shoots and buds at this stage; examine curled-up leaves as the grub *f* will come out from *g*, quickly, and destroy it. The grub is shown at *h*, made clear, eating a young bud *i*. All eaten buds are useless. Plants free at night are infested the next morning.

ROSES IN POTS AND UNDER GLASS.

Plants that were flowered under glass in pots should be snugly placed on a bed of ashes outside and the pots buried to their rims in ashes or well rotted leaf-soil. The treatment during the summer months is very simple and consists of attention to watering and the removal of any buds that form, also young sub-lateral shoots, but do not cut away any of the hard wood. From this date to the end of September re-potting or top-dressing work should be done. As a guide as to the exact treatment most suitable at this stage, I may say, turn out the old balls of soil from the pots; if roots are plentiful, in fact, almost forming a network round the old balls of soil, it is a sure indication that re-potting is necessary. If there are not many roots visible, then top-dressing only will be sufficient. When re-potting, shift the plants to pots just one size larger than the old ones; if top-dressing is done, remove the old soil from the surface low enough to expose a few of the top roots. For both re-potting and top-dressing use a compost of fibrous loam with a 6in. potful of bonemeal added to each bushel. Secure sound drainage and pot firmly. Water carefully and leave the pruning till the end of the year, keeping the plants outside till late autumn. Permanent plants under glass should be kept as cool as possible and free from aphides. Prune in December.

POTATOES.

In some parts of the country potatoes will be quite satisfactory, in others they will be very unsatisfactory. I am referring now to crops generally—early, medium and late. Cultivators should not save seeds from their own gardens of any variety more than two years, after the second year the resultant crop, from home-saved tubers, often develops rust and the common diseases very badly and fail, too, to yield a full crop. A change of seed is beneficial and those obtaining it should always procure tubers from gardens and farms as far north as is possible of their own. But even seed from a neighbour's garden in the same village or district is better than one's own, after the second year. Now, just a few hints on saving one's own tubers for next year's planting. In each quarter and of each distinct variety, the best roots should be selected—those least ripened and possessing the most robust haulm. Lift these roots separately and retain seed tubers from them, not generally as the crop is lifted. Of course, a certain amount of exposure and greening is essential, but the tubers should never be allowed to get wet nor be unduly exposed to the sun. An ideal position for the tubers in shallow boxes is under tilted lights in a cold frame with mats on the glass for several weeks prior to placing them in the winter quarters. They should always be kept perfectly dry and in a cool even temperature so that they will remain dormant.

GEORGE GARNER.

FAIR CROWNS. II—DELPHI AND APOLLO'S LAUREL

WE hear little of those apples mentioned by Solon as Pythian prizes, although they are represented on coins of Delphi, together with laurel wreaths. Probably they vanished all too quickly, and leaves would be a more permanent souvenir, and more akin to the Olympian prizes. The Pythian games, celebrated at Apollo's stronghold, Delphi, were only second to those of Olympia, and were a development of a small local festival devoted to Apollo and his lyre. These neighbourly competitions, chiefly musical, were reorganised as funeral games in honour of the victims who fought in the First Sacred War and in defence of Delphi. Such funeral games were common in old Greece, perhaps survivals of prehistoric sacrifices of prisoners or slaves at the graves of their masters, or of the sham battles which took their place; or perhaps it was thought that the souls of the dead would be pleased with the same sport as the living. In Homer's day, and later, they were merely contests of skill with weapons or muscles, between guests at the tombs of the great or in honour of them.

But, as in Olympia, people clung to the old picturesque legends explaining habits of which they knew not the origin. Delphians gloried in tales of Apollo and in his conquest over the huge serpent, or dragon, Pytho, the guardian of the oracle of Earth, an ancient shrine which preceded that of Apollo. Some said that the monster was ravaging the country when stopped by the arrows of the sun-god. As was customary after shedding blood, Apollo was ordered by Zeus to purify himself, a rite usually managed by sprinkling pure water on the culprit either with a torch from the altar, or with a branch of laurel, or even of olive. Therefore the god betook himself to the laurel thickets of the Vale of Tempe, at the foot of Mount Olympus, and tore off branches for this purpose and to crown himself, and to carry in his hand. Having fulfilled his penance, he went back to Delphi, and took possession of the now unguarded shrine of Earth—a curious fissure in the ground whence fumes giving extraordinary powers of prophecy were supposed to issue, took it over and made it one of the most famous oracles of antiquity. But the laurel tree in the vale from which he tore the boughs of "lustration" was providentially noted, and an altar erected beneath it. Thence were taken those sprays of laurel that were woven into crowns of victory for the games which were called Pythian, either in memory of the slaughter of the dragon, Pytho, or because the town itself was occasionally called Pytho also.

Laurels grew around the shrine itself and about the temple, and were always used in rites of worship of this sun-god; and to explain their presence, the legendary tale of Daphne arose. That innocent damsel was trying to escape from the unwelcome caresses of Apollo, and called for help to her mother the Earth—the same goddess whose oracle had been stolen by the god. In answer, a chasm opened beneath her feet and into it she slipped as a refuge. A laurel tree marvellously sprang up in her place, and when the pursuer arrived all he found was a handful of bays. The townsfolk probably believed that this happened at the oracular chasm, and that the very shrub imprisoning the nymph was still standing before the temple or in the Cave of Prophecies, casting its sombre shades over the Pythia, as the priestess of Apollo was called, when she was not referred to as a "bee." Here, having drunk of a sacred spring, fumigated herself with laurel leaves, and even chewed its sacred foliage, the priestess settled herself on a tripod over the marvellous earth-fissure, grasped the near-by laurel's trunk and invoked the sun-god. His presence was indicated by the shivering and rustling of his laurels, and thence he inspired the Pythia, who then uttered vague sentences, prophecies and commands, difficult to understand or to follow, but which were obeyed by all Greece as far as possible.

Now we understand why, since musical and dramatic competitions were important events at the Pythian games, centring about a Hymn to Apollo which related his exploits, the laurel crown became intimately associated with the arts, fostered by Apollo and his companions, the Muses. This artistic use of the laurel continued long after the last Pythian crown had crumbled into dust, just as laurel, in another aspect, as a symbol of victory, lingered long with the common people. Figuratively speaking, the custom of crowning a poet with "bays" has survived to this day, for England still appoints her "Poet Laureate." H. INGERSOLL.

FLOWERS AT HAYWARD'S HEATH

THE thirty-fourth exhibition of the Hayward's Heath and Mid-Sussex Horticultural Society was held in Victoria Park on July 29th and July 30th. This horticultural society is one which possesses some excellent gardeners as its members, and the show promises to develop yearly. The Hayward's Heath district is particularly favourable to the horticulturist, both from the climatic and soil points of view. A show held in this neighbourhood is well worth a visit from nurseryman or amateur, and an exhibit from either would not be wasted effort on the part of the exhibitor.

Some splendid exhibits were staged by the trade and amateurs. In the private section competition was very keen. The quality of the fruit, nearly all of which came from local gardens, was excellent. Mr. W. J. Yapp (gardener, Mr. H. Manton) again won the Paxhill Park Challenge Trophy for an exhibit of twelve dishes of ripe fruit. The cherries, grapes and peaches were perfect. Mr. C. T. Allen (gardener, Mr. F. L. Telling) won prizes for grapes, melons, tomatoes and cucumbers. The fine size and condition of the specimens deserve praise. The peaches grown by Mr. A. E. Pattenden, the gardener of Mr. R. Carver, were remarkably good. The exhibits of the Right Hon. Lord Denman (gardener, Mr. W. Mackay) were well grown and well displayed, and many of them won first prizes. Mr. W. Manton, gardener to the Misses Helme, arranged a good collection of hardy fruit.

In the section for single-handed gardeners and amateurs the number of exhibits in each class were small. Prize tomatoes were shown in this division by Mrs. Ivatt (gardener, Mr. C. Holman) and cucumbers by Mr. L. H. Strouts (gardener, Mr. A. Laker). A most successful exhibitor of fruit and vegetables was Mr. G. Thomas. Gooseberries and currants, particularly red currants, were of good quality. The specimens shown by Mr. G. Thomas were healthy, of even size and in perfect condition.

A collection of perennials shown by Mr. W. J. Yapp won the Society's "Coming-of-Age" Challenge Trophy. This same exhibitor was again this year awarded the Stewart Mackenzie of Seaforth Carnation Challenge Trophy for a display of perpetual carnations. The beautiful spikes of large-flowered gladioli and primulinus hybrids grown by Mr. W. D. Mackay were much admired. Carnations and star dahlias were well shown by Mrs. T. P. Warren (gardener, Mr. H. Nailor). When compared with the other floral exhibits, the sweet peas and roses were not outstanding, the stems were short and the flowers inferior in colour. The James Box Sweet Pea Cup went to Mrs. T. P. Warren. Phlox Elizabeth Campbell and Baron von Dedem were the two best varieties shown by Mr. W. S. Pool (gardener, Mr. J. G. Caswell). Good stocks were exhibited by Mr. Bridgden in the cottagers' section.

The collections of a number of distinct kinds of vegetables were admirably staged. Dr. G. T. Walters (gardener, Mr. C. Harris) was again successful in winning the Society's Coronation Challenge Bowl for a collection of vegetables. A very creditable group was staged by the Scaynes Hill Women's Institute. The peas and carrots exhibits were of good quality in nearly every case. Mrs. T. P. Warren and Mr. J. White showed prize potatoes. Well ripened onions were shown by Mr. W. D. Mackay. Peas and beans grown by Mr. W. Manton, won prizes, and Mr. P. W. Carver was successful in several classes. The *Mid-Sussex Times* Challenge Cup for vegetables was awarded to Mr. G. Keen.

A good group of gloxinias was staged by Mr. T. W. Thompson (gardener, Mr. R. T. Axbel) and a table of greenhouse plants by Mrs. Ivatt. Mrs. T. Sydenham won the silver challenge cup for table decoration in the ladies' section. The baskets of flowers and foliage were very good, Mrs. A. M. Swann gaining the first prize. In the children's section interesting collections of well named wild flowers were exhibited.

Several excellent trade exhibits made striking patches of colour in the tent. Mr. Elisha Hicks was to be congratulated on his first prize stand of roses. The arrangement and condition of the blooms left nothing to be desired. Beautiful blooms of W. F. Dreer, Los Angeles, the sweetly scented Mrs. E. Powell, together with Betty Uprichard, one of the best of the newer roses, were artistically displayed. At one end of the tent a prominent ground exhibit of hardy flowers was staged by Mr. James Box of Hayward's Heath, and at the other end Messrs. Allwood Brothers made a fine display with their carnations. Mr. James Box had a small lily pool in the centre of his group, and surrounding it were water-loving plants. At the back of this hardy flowers of all kinds were set out in a semi-circular bed. Messrs. Allwood Brothers showed several of their 1925 novelties, such as Beauty of Durham and M. M. Stoop, together with perfect blooms of Coral Glow and Laddie.

A wonderful collection of beautiful orchids was shown by Messrs. Charlesworth. Many fine varieties and species were included, and all in excellent condition. The Chez Nous Nurseries had an interesting exhibit of miniature Japanese gardens and dwarf Japanese trees in bowls. Roses were shown by Mr. Frank Woollard and Messrs. J. Cheals had many fine perennials among their exhibit of hardy flowers. Herbaceous plants, shrubs, climbers, alpines and gooseberries were shown by Mr. H. Hemsley. The stock-flowered larkspurs shown by Messrs. Daniel Brothers were greatly admired.

THE SPREAD OF GARDENING IN AMERICA

WHEN the Garden Club of America visited the old gardens of Virginia this spring as the guests of the James River Garden Club, they felt themselves at the source of fine gardening in their country. Those old gardens have in them still the very flavour of England, that quiet beauty which only age can bring. And from England it was, of course, that the dwellers in old Virginia brought their love of gardening, their idea of the garden. Other parts of America, however, had gardens, too, in our early time—Philadelphia. New York, with the gardens of the Dutch, and much later, Rochester, New York, where gardening has flourished exceedingly for many years.

There was a time, however—perhaps about the 'sixties and 'seventies—when the pursuit was limited generally to a small amount of bedding out. A few fine old gardens were dear to their owners in various States, but the rank and file cared nothing for them. Then appeared a few gardening books, and a good monthly periodical devoted to gardening alone. This brought fresh life to the various horticultural societies of the country, and so the first garden club was born—the Garden Club of Philadelphia. This event—it has become an event, though not then so considered by its founders—has proved to be the one which more than any other has brought gardening and the love of gardening to Americans. We are known as passionate organisers; and no doubt it has hurt some amateurs to see our organising carried into this personal field. But see what this has done for America. Not only did the Garden Club of America spring from this Garden Club of Philadelphia, but hundreds of other clubs are now in active, happy existence, which, but for such organising, would not have been formed.

The Garden Club of America, of which Mrs. Samuel Sloan is president, is an organisation or more than sixty member clubs, with committees on such subjects as colour charts for flowers, bill-boards and road sides, international relations (which means nothing less gentle than visits to gardens of other countries), visiting gardens in our own country, flower shows, the national capital conservation of wild flowers, historic gardens and so on. A remarkably fine bulletin for members appears six times a year. This organisation is a very powerful one. It has a membership of clubs, not of individuals. Its effect on gardening as an art, is already vital, and the many garden clubs now springing up all over the land are due in large measure to the example and stimulus of the Garden Club of America. Forty garden clubs in New York State alone have lately formed a group of their own. This federation, according to one of its members, hopes to encourage "the garden for the poor, the near poor and the well-to-do." Besides these groups many garden clubs are coming into existence from month to month in all the States. The movement is growing rapidly. The Garden Club of America welcomes the formation of the Garden Club, Limited, in London, and has already pleasant intercourse with the new society.

Another group which encourages gardening, is the Woman's National Farm and Garden Association. This helps also to form garden clubs, though its main objects are more nearly related to those of the Women's Institutes of England, with which it has most friendly relations. The Society of Little Gardens of Philadelphia is doing a fine work; so is the City Gardens Club of New York. And in women's clubs throughout the country there are now many so-called garden departments which press the subject continually.

So far I have named only women's organisations. I remember Mr. E. A. Bowles' writing me once that he believed women were more interested in colour effects in gardening than in the individual plant; that men, he thought, preferred to deal with the latter. In view of this comment, it is really interesting to notice that men are foremost here in the special plant society. Men started the garden movement in America long ago, through the founding of the great horticultural societies of Philadelphia, Massachusetts and New York. In New York such men as the great botanist, Dr. N. L. Britton, Mr. Frederick Newbold, Mr. T. A. Havemeyer, in Boston the late Richard T. Saltonstall, Mr. A. C. Burrage, whose orchids have world-wide fame, are some of the leaders in these societies; while Professor Saunders in the Peony Society, Mr. John C. Wister in the Iris Society, and Mr. Horace McFarland in that of the rose, are certainly among the best of our amateurs and have made distinct contributions to American horticulture. To Mrs. Edward Harding, too, and to Mrs. Charles H. Stout, are due much of the present interest in the peony and the dahlia.

Of gardening periodicals for the amateurs, we have but two or three. We need a weekly like THE GARDEN. Flower shows are held now almost daily in all parts of the country, and at all seasons of the year. Here may I let the eagle flap his wings a little, and say that even in December and January in our wide land. shows of flowers grown in the open are held in Florida and California. They sometimes occur in unlooked-for buildings; banks welcome them to their foyers. In Michigan there is a growing tendency in its smaller cities, to have exhibitions of irises, peonies and gladioli, three flowers which men seem particularly to fancy. The great botanic gardens of the country are to-day immensely popular, the Arnold Arboretum (presided over by Professor Sargent, with Mr. E. H. Wilson as its explorer), the New York Botanic Garden, and that at St. Louis, Missouri. We look for a National Arboretum soon at Washington.

Our general type of garden, our best garden, is, I think, the modified English one. There are some great gardens Italianesque or English in manner; but it is the gardens of moderate or modest size that are generally being made to-day. As our houses grow within and without quieter, more comfortable in architectural lines, so our gardens begin to seem like parts of our houses, our actual places for living. What we owe to the great William Robinson, to Miss Jekyll, cannot be put into words. We can only say warmly to you in Britain, "Come into our gardens and we will show you what we have inherited from, and tried to learn from you."

I have named some of the concrete agencies at work in America toward the spreading of the garden. But there is another all-powerful one, without which organisations, societies, arboreta, could do little. It is the impulse toward beauty, which brings everyone in time to see that in a garden lies a happiness that is in no other possession. FRANCIS KING.

RANUNCULUS FICARIA (THE LESSER CELANDINE).

THIS little plant is not a true member of the Ranunculaceæ order, which has its sepals and petals in fives or multiples of fives. The lesser celandine has three deciduous instead of five persistent sepals and nine petals. Last spring I came across what is to me a new variety of this plant, one with double flowers. It was growing among masses of the ordinary single-flowered plants, and there were blossoms in every stage of doubling, from two whorls of petals to a densely petalled flower. The owner of the garden has left all these plants undisturbed and for many years the double-flowered variety has been gradually ousting its single-flowered relative. Clumps of the newer variety have made their appearance in quite another part of the garden. They appear to have a more compact growth than the single variety. This plant would be a pretty addition to the wild garden and a valuable one to the rock garden, as it blossoms so early in the year. I cannot share your poetical correspondent's aversion for the lesser celandine or see that it is a nuisance, as, so soon as it has blossomed, it modestly disappears. Old Gerarde thus described it: "It cometh forth about the Calends of March, and floureth a little after; it beginneth to fade in Aprill; it is quite gone in May and afterwards it is hard to be found; yea scarcely the root of it."

Many plants appear to change their characteristics by their own accord. One example is the bee orchis, which was at one time entirely fertilised by insects, but has for many years been tending towards self-fertilisation.

Then there is the yellow musk, which in the last fifty years has almost entirely ceased to manufacture scent. (There are rare cases where scented musk can still be found, but these become scarcer every year. In 1914 I found a clump of sweet-smelling musk near Guildford. In 1918 it was scentless!)

The musk has, apparently, found out how to fertilise itself, and so no longer need waste its energy in manufacturing scent to attract insects.

The double R. ficaria has modified the stamens of the single flower into petals, and so ceased to make pollen. At first sight this certainly appears to be an attempt to kill out its species, but if we go more deeply into the matter we may discover that this is not the case. Another native plant, Cardamine pratensis (lady's smock), has in some districts produced a double-flowered variety which has very gradually killed out all the

Digitized by Google

single ones in its vicinity. C. pratensis evidently thought the matter well out, for, while nullifying its stamens, it evolved a scheme for continuing its race without them. Indeed, the double variety is much more prolific than the more frequent single-flowered lady's smock, or cuckoo flower, for each leaflet sends out roots and becomes a new plant so soon as it touches the ground. As they wither the flowers send up a flower bud from their centre which is *sometimes* single. May not the bee orchis, the musk and the lesser celandine have some such plan in their mystic minds? Such means of propagation is an evolution, since the manufacture of pollen and the formation of seeds—*i.e.*, sexual propagation—require a vast amount of energy from the plant and are done without by double-flowered plants. In the course of years the bee orchis and the musk, instead of fertilising themselves, may evolve a sexual reproduction.

There may be yet another reason for R. ficaria producing double blossoms. It flowers at a time of year when there is little sun and when very few insects are about to cross-fertilise its flowers. So perhaps it is to save itself from extinction that this particular colony of lesser celandines is turning its stamens into petals. VICTORIA SLADE.

KILLING SLUGS—A SIMPLE AND SUCCESSFUL METHOD.

WHEN a small boy, I was much addicted to "chemical experiments." Once I tried the effect of putting a slug into ammonia. The slug "fizzed up," dissolved away, and formed a jelly. The original experiment can be easily repeated. Most people keep ammonia in the house, and most people have an ample supply of slugs in their gardens!

During the war it so happened that my house and garden stood for long empty and neglected. When I again took steps to rehabilitate the garden, the slug pest had assumed prodigious dimensions. Gathering slugs by hand is a weariness to the flesh, especially about the small of the back. I called to mind my youthful experiment, and applied the discovery. The result was altogether successful. The method may not be new, but I never heard of it before, I imagine there will be many others in like case.

Buy from a wholesale drysalter a bottle of the strongest liquid ammonia. This is sold in "Winchester quarts" (rather less than a gallon), and is not expensive.

This ammonia is called by the trade name of "eighty-eight" ammonia. It is very strong. It is not a poison in the ordinary sense, but it is corrosive. It will burn skin or clothes and must be handled with care. If any does get on to hand or garments, wet the place with vinegar. This will neutralise the ammonia.

Do all mixing outside, and keep on the side from which the wind is blowing. One good sniff of this strong ammonia will make you take jolly good care to avoid a second! Do not mix more at a time than you are going to use, because, unless kept in a sealed vessel, it will go stale.

To produce a good working strength for use in the garden, mix about two breakfast cupfuls of the "eighty-eight" ammonia with two gallons of water. Very accurate measure is not essential. The mixture should just have a pretty distinct smell of ammonia.

Use an ordinary watering can with a rose, and after dark, when the slugs will be abroad, water the rows of plants. Every slug that comes in contact with the solution will cease to be, while the plants will not be injured in any way. On the contrary, the ammonia is of some manurial value. W. J. G. F.

BOOK REVIEWS

A MOST interesting and instructive French volume on ornamental trees and shrubs has come to our notice, "Les Arbres et Arbustes d'Ornement," by S. Mottet; published by J. B. Baillière et Fils, éditeurs, 19, rue Hautefeuille, Paris, price 50 francs.

After a few preliminary remarks on the constitution of trees and shrubs, their value in the garden from an ornamental point of view and the various uses to which they can be put either as isolated plants or in clumps, the author devotes the greater part of the work to an enumeration and description of woody, climbing and shrubby genera and species and their principal varieties which adorn our gardens at the present day. In addition quite a number of the most interesting new species which have been introduced from China during the last thirty years are figured and described. This section, which covers some 470 pages, is brought to a close by a descriptive table of 2,500 species, including many of minor interest.

Following this are a few chapters devoted to propagation, planting and other cultural details, such as pruning, much the same rules being laid down as those met with in English manuals on the same subject. Finally, a useful list of choice trees and shrubs selected for various purposes with regard to soil, climatic and general topographical conditions is given. This list will provide a valuable mnemonic to all professional growers and a serviceable guide to all amateurs who are faced with difficulties when planting for effect. The genera and species have been treated under their family groups, in each family the genera following alphabetically. Latin nomenclature is adhered to, while in the majority of cases the common name is supplied, which will greatly facilitate the work of reference.

The volume is dedicated to the memory of the late M. Maurice L. de Vilmorin, one of the pioneers of French horticulture, with whom the author was closely associated for a long period, being in charge of all the experimental work at the establishment of Messrs. Vilmorin's at Verrières-le-Buisson.

The book will be found of great service to all nurserymen and to amateurs who have already gained a little knowledge of trees and shrubs. To students of horticulture and forestry it is recommended as a work which gives a concise and clear exposition of the treatment of trees and shrubs, with the proviso, however, that the reader must have a knowledge of French.

THE title of this book, namely, "A Garden Timepiece," by M. G. Kennedy-Bell (Hutchinson and Co., Paternoster Row, E.C.4, price 7s. 6d. net), fascinates me. One is led to expect that indefinable something which is genuinely wanting in gardening books, and one's expectations are fully realised on turning over its pages. It is a well balanced book on gardening, in which the æsthetic and artistic sides of the subject are cleverly woven into an interesting story along with more practical and everyday details and problems with which the average gardener has to contend. The year's work is dealt with in a thoroughly business-like manner, indicating that the author is well acquainted with her subject, and the book serves as an excellent all-round guide to all gardening enthusiasts. It is charmingly written, yet withal it does not lose that vital force which is so necessary to a practical manual. The illustrations are of the very best, being the work of the late Mr. R. A. Malby, and these greatly enhance the value of the volume, which one can thoroughly recommend to all garden lovers. G. C. T.

THIS volume, "Systematic Pomology," by U. P. Hendrick (Rural Text Book Series, published by the Macmillan Company, New York, price 17s.), contains a systematic account of the commonest fruits represented by the best commercial and more widely known varieties in cultivation in America. As such it will prove useful to the practical as well as to the theoretical man in the identification of fruits. The book certainly marks a great advance in pomological study, and we on this side will find it instructive on that account. The first few chapters are devoted to general botany, which is a useful feature in a manual of this description. A chapter is given to each of the commoner fruits, such as the apple, pear, cherry, etc., wherein are discussed their characteristics and general cultivation. In looking through a systematic volume such as this is, we cannot but put forward a plea for the establishment of some international system of nomenclature which would at least tend to lessen the duplication and confusion which exists in some of these newer branches of botanical study.

PUBLICATIONS RECEIVED.

"A Class Book of Botany," by Ernest Stenhouse. (Macmillan and Co., Limited, St. Martin's Street, price 7s. 6d.)

"Plants and Man," by Professor F. O. Bower. (Macmillan and Co., price 14s.)

"The Journal of Pomology and Horticultural Science, Vol. IV, Nos. 3 and 4. (Headley Brothers, Bishopsgate, price 5s.)

CATALOGUES RECEIVED.

Messrs. Hazlewood Bros., Epping, New South Wales, Australia.—A useful list of roses, ornamental trees and choice flowering shrubs, giving brief notes on rose culture, with special reference to disease and also to the climatic conditions met with in Australia. One or two excellent half-tone illustrations enhance the value of this catalogue which we recommend to any of our readers interested.

Charles Turner, The Royal Nurseries, Slough.—List of Dahlias for 1925 including many fine new varieties.

One of the earliest bulb catalogues to appear this year is that of Messrs. Carters of Raynes Park. Besides consisting of lists of everything that a garden requires in the way of bulbs, this catalogue is noticeable for the excellence of its production. In the past, prospective buyers of seeds or plants have had to rely a great deal on their imagination owing to the lack of illustrations and inadequate descriptions, but since the war seedsmen and nurserymen have begun to improve their catalogue productions. For the number and quality of the illustrations this catalogue of Messrs. Carters is one of the finest that we have ever seen. The coloured cover is a reproduction of their admirable stand at this year's Ideal Home Exhibition, while the half-tone illustrations could hardly be bettered.

Messrs. Laxton Brothers, Bedford.—Strawberries and Small Fruits.

FOREIGN.

Messrs. J. B. Vanderschoot, Hillegom, Holland.—A well illustrated catalogue containing useful lists of all bulbous plants.

Messrs. W. C. Roozen and Co., Limited, Overveen, Haarlem, Holland.—A well illustrated List of Dutch Bulbs and Other Plants for 1925–26.

Windsor Rose Show.—An error occurred in our report of this show in the issue of July 25th. The report should have read "Messrs. D. Prior and Sons have won the King's Cup three times, while Messrs. Frank Cant and Co. have won it now two years in succession, including this year."

Price Threepence. Yearly Subscription, Inland, 17s. 4d.; Foreign, 17s. 4d. Registered at the General Post Office as a Newspaper and for Canadian Magazine Post.
Editorial Offices: 20, TAVISTOCK STREET, COVENT GARDEN, W.C.2. *Offices for Advertisements:* 8–11, SOUTHAMPTON STREET, STRAND, W.C.2.
Entered as Second-class Matter at the New York, N.Y., Post Office.

THE PROTECTION OF WILD FLOWERS

MANY of our readers will have read the appeal of August 10th for the protection of wild flowers, issued by the Society for the Promotion of Nature Reserves, of which Lord Ullswater is President and Sir Sidney Harmer the Honorary Treasurer.

For the information of those who did not see this, we print below the actual appeal.

"The Council of the Society for the Promotion of Nature Reserves has learnt with concern that many species of wild flowers and ferns in various parts of the country are in real danger of being exterminated, owing to heavy picking of the flowers or uprooting of the plants. The gravity of the danger has been increased by the greater accessibility of the country districts as a consequence of the development of motor vehicles. The extermination of any of the native flora would often adversely affect the amenities of the countryside, and would be an irreparable blow to the scientific study of this branch of botany. The Council, therefore, appeals to the county councils to take the necessary steps for the protection of the wild flowers in their several districts, by the issue of by-laws or in such other ways as may seem desirable to them. Much of the damage may be due to thoughtlessness and ignorance, and good results might be obtained if notices requesting the public not to pick the flowers or remove the plants were placed in suitable places and if, also, in such districts the children in the schools could be instructed in the harmfulness of heavily picking flowers or removing plants. It might be desirable in certain instances to constitute reservations for the protection of rare species. The Council respectfully commends the above suggestions to the consideration of the several county councils, which are so concerned with the welfare and education of the people of Great Britain.

In addition, the *Times* published a statement by Sir Sidney Harmer, who is Director of the Natural History Museum.

There is no doubt that this appeal is timely, for the destruction of our wild flora is enormous in parts of the country which are used as playgrounds by urban dwellers. The popularity of the char-à-bancs has opened out areas which, even before the war, were secluded and rarely visited by the town dweller.

Another cause is undoubtedly what the *Times* calls suburbanisation. The inhabitant of one of these mushroom garden cities is the same as every other Britisher, inclined to be inquisitive, and one of his first ploys is to explore the surrounding country, with the consequent transference of a number of wild plants to his own garden. This means a temporary decrease of wild flora in the surrounding district, but surely it is only temporary. The actual urban dweller is unknowingly much more destructive, for I know from experience the number of discarded bunches of wild flowers which are strewn along many country roads on a hot week-end. The city dweller in his first exuberance at being in the country on a fine day, allows his enthusiasm to run away and picks here, there and everywhere, with the laudable intention of retaining the memory of his day for as long as possible, by having flowers in the house, without realising the toil of carrying home a large bunch of flowers, always an awkward thing to handle.

Publicity is the obvious way to put a stop to this indiscriminate picking of the commoner wild flowers, publicity in the schools, above all, for children are the worst offenders. Notices on the roads should also help. The Society suggests the passing of by-laws by the local authorities, a suggestion to which I, personally, have the strongest objection. The British Isles is already sufficiently bureaucratic to make any addition to our laws and by-laws an immediate object of suspicion. For the city dweller to have his rare outings in the country controlled for him by orders that he must do this and must not do that is quite intolerable. The fault is caused by ignorance, not wilfully, and publicity is surely the obvious remedy. So much for the ordinary wild flower.

The rarer flora presents an entirely different problem. It must be remembered that a plant's rarity is not necessarily brought about by the depredations of human beings; also it must be remembered that the number of rare plants which are worthy of being grown in our gardens is comparatively few and that most of them are plants of the highlands and not of the lowlands. If some rather insignificant rarity has disappeared through a human agency, the botanists have themselves to blame, for only they know of its rarity. Saxifraga cernua, one of the least showy, but the rarest, of our native saxifrages, is a case in point. A fat clump of it existed to within the last year or two on the top of a certain Scottish Ben. Now it has almost disappeared. It is certainly not the fault of gardeners.

Unfortunately, it is the apparent loss of some of the lowland plants which is most severely felt. Sir Sidney Harmer points out the disappearance of Daphne Mezereum, the wild seakale, the Lady's Slipper and Osmunda regalis. Both from the loss of beauty and from the ecological side, this is

Digitized by Google

unfortunate, but the loss falls chiefly on the latter, for three out of the four plants are common in gardens, and could be replanted again in their old haunts without very much trouble.

Personally, I doubt if the decrease in rare plants is so extensive as is imagined, except, possibly, within fifty miles of London. It is next to impossible to gauge the supply of a particular plant, for excellent field botanists, many of them unknown, have realised for a number of years the possibilities of extermination of rare species in their respective neighbourhoods and have guarded their knowledge jealously. I think we may take it that the rock garden has more scope for native plants than any other form of garden. I have seen dozens of excellent rock gardens, but only in the case of one, that I know of, does the owner search for British plants.

From the increasing interest taken by British gardeners in collecting in the Alps, it might be inferred that the same applies in our own hills. The case, however, is not analogous, for the enthusiast goes to the Alps to collect plants. On our own hills he shoots or stalks or fishes. His pursuits are different.

Some time ago a scheme was proposed for the formation of a national rock garden on the top of Snowdon, where all our British alpines could be collected and grown under observation. I have not heard anything further about it for at least a year, but it seems to me that a series of such gardens—one for cliffs, one for woodland, and so on—would be an excellent means of solving the question of the preservation of our native plants. The Swiss have done it with excellent results. The French were also testing it before the war at La Grave, above Grenoble, but apparently have not restarted it since the armistice. The original cost would not be heavy and the cost of upkeep would be light. Only three rules would be required in such a garden; that no plant should be picked, that no fire should be lighted, that no waste paper or refuse should be left on the ground.

This idea of entirely natural gardening has already received a strong impetus in this country with the formation of the arboretum at Bedgebury, under the auspices of Kew, and of Benmore, in Argyllshire, under the Forestry Commission, and of the wild garden at Glen Branter, which has been started by the Royal Botanic Garden, Edinburgh, as a testing ground for rhododendrons. It will be noticed that these three schemes are almost entirely given up to the cultivation of exotic plants and laudable though they may be, it seems to me that they might well be followed by similar schemes which would be entirely devoted to our own natives. E. H. M. C.

THE STEWARTIAS

THIS interesting genus of hardy shrubs, or small trees, has botanical affinities with the wild camellias. Both belong to the Natural Order Ternstrœmiaceæ, but the stewartias are deciduous and the camellias evergreen shrubs. Some confusion exists in the spelling of the name. In nurseries it is usually spelt "stuartia," but in the new Kew Hand-list of Trees and Shrubs and in Vol. II of Mr. Bean's book, "Trees and Shrubs Hardy in the British Isles," it is spelt "stewartia."

The genus is represented in our gardens to-day by six species, two from the eastern United States, three from Japan and one from China. It is on record that S. malachodendron was flowering in Mark Catesby's garden at Fulham in 1742, and that S. pentagyna was first introduced to British gardens in 1785. The stewartias, however, are comparatively little cultivated to-day, though they are most interesting and desirable shrubs, flowering in July and August.

THE DAINTILY CRIMPED AND CREAMY WHITE BLOSSOMS OF S. PENTAGYNA.

S. malachodendron, a native of the south-eastern United States, is a deciduous shrub up to some 15ft. to 20ft. in height. I recently saw a specimen approaching the latter height growing in a garden containing many interesting shrubs at Iver Heath, Bucks. The flowers are solitary, borne singly from the leaf axils during July and August, 3ins. to 4ins. in diameter, with five white petals and a central cluster of purplish stamens. Another name for this interesting species is S. virginica, recording obviously its native habitat. It is figured in the *Botanical Magazine*, tab. 8145.

S. pentagyna is a native of the southern United States. It is more spreading in habit than the last named, 10ft. to 15ft. in height, and as much or more in diameter. The blossoms are produced singly in the leaf axils during July and August. They are creamy white, sometimes with a tint of red on the outside, the edges daintily crimped 3ins. to 4ins. across with a central cluster of yellow stamens. The variety grandiflora, as the name suggests, is a form with slightly larger flowers and purple stamens.

S. pseudo-camellia is one of the tallest members of the stewartia family. Professor Sargent during his travels in Japan met with trees up to 50ft. in height with a trunk 6ft. in circumference. In gardens specimens are readily recognised by the upright habit of growth. The white, cupped blossoms are not so large as the American species, being 2ins. to 2½ins. across, produced singly in the leaf axils towards the end of July and early in August. The orange yellow stamens clustered in the centre of the flowers are showy.

S. sinensis is a native of China, and was first introduced by Mr. E. H. Wilson in 1901. He records it as a shrub or small tree varying from 6ft. to 30ft. in height, native of Eastern Szechuan and Western Hupeh. Plants have flowered in several British gardens. The first I saw were sent to Kew from a Devonshire garden in July, 1917. They were white, 1½ins. to 2ins. in diameter.

Two other Japanese species are in cultivation, S. monadelpha, and S. serrata, said to be a common wild tree in Japan 50ft. to 75ft. in height.

PROPAGATION.

The stewartias are not difficult to propagate by seeds, cuttings and layering. Increase by seeds is obviously the best

Digitized by Google

method when obtainable, though if one possesses a plant with branches near the ground layering is readily accomplished. Cuttings made of the half-ripe new shoots can be rooted in a sand frame with slight bottom heat during July, and later in the season more mature wood can be inserted in sandy soil under a west wall and covered with a cloche.

Provided it is well drained, stewartias thrive in peat or light loamy soil. When preparing positions for planting, add leaf-mould and peat to loamy soils, and sandy loam and leaf-mould to peat ground. At Kew the best plants are growing in beds of the Mediterranean heaths, which served as a protection when they were young and keep the surface soil cool in summer. One important cultural consideration is to plant in cultivated beds or borders where the surface soil can be stirred, and mulch with liberal supplies of leaf-mould and old hot-bed or mushroom manure.

A. OSBORN.

THE UTILISATION OF GLASSHOUSES

THIS IS AN ARTICLE TO SHOW HOW A GREENHOUSE CAN BE MADE TO GIVE A HANDSOME RETURN BY FORCING EARLY VEGETABLES FOR WHICH HIGH PRICES ARE OFTEN GIVEN.

I HAVE just completed a round tour of the British Isles, and have visited hundreds of establishments where the proper uses of glass does not seem to be fully appreciated. I saw and interviewed many disgruntled gardeners, who complained that their employers were jibbing at the cost of the gardens—"As if they were meant to pay" I was informed! But on carefully looking round I found ample evidence that, even though they knew it not, the employers were more than justified in their attitude. Glasshouses were full of rubbish—canes, raffia, old cans—all the impedimenta associated with gardening.

Now to give shelter to these necessary but most untidy-looking articles under glass is decidedly not economical, and I propose to proceed to talk about certain crops which, at this time of the year, might well be grown to advantage and financial profit—two items which do not usually go together. Let us deal with beans and mint first.

MINT AND BEANS.

Each of these crops may be grown either in frames or heated glass houses at very little cost. The best bean to grow is the French dwarf variety known as Canadian Wonder. It is a heavy cropper and has a nice, long, dark green pod well known and liked by salesmen. Another kind which might well precede Canadian Wonder is Earliest of All. This sort is a bit quicker coming to maturity than most, but does not crop so heavily. It also likes a little more heat. The beans may be planted at once in thumb pots and allowed to germinate in the warmer atmosphere of the propagating pits. When the two seed leaves are well out, spray the plants daily with water until the leaves have thoroughly expanded.

A SAMPLE OF EARLY POTATOES GROWN ON THE FLOOR OF A HOUSE.

They may then be planted into large chrysanthemum pots, two to a pot, and placed in their permanent quarters. Start them off with a day temperature of 70° to 75°, with 10° less for the night. The great tip is to force beans very rapidly, so that they are tender and of a good length. Cease spraying the plants as soon as they commence to come into flower, and keep the house as dry as possible. Water twice a week with a dilute solution of liquid manure. When it is seen that the flowers have "set" and the young beans are "running," raise the temperature to 85° to 90° until fit to pick, which will be when the pods are from 6ins. to 8ins. in length. The whole crop should be taken in two pickings at about ten days apart. When ready for market the salesman should be informed what to expect the day before they will be despatched, for beans are very expensive. The small wooden "twelve pound" tomato box is an ideal package in which to market the crop, and the boxes should contain an even number of pounds. Lay the beans evenly in the container after first covering the inside of it with blue tissue paper. The box should be quite full and tight after packing, otherwise the beans will shift about during transit and will arrive in the market bruised and broken and valueless.

FORCED BEANS IN A GREENHOUSE WITH A BACKGROUND OF TOMATOES.

For really good stuff, young and well grown, the sender may expect to receive as much as 10s. to 12s. per pound during February and March. After then the price gradually drops to 2s., at which price it hardly pays to grow. When finished, the plants should be removed and the house got ready for tomatoes.

Mint is one of the most profitable crops I know of to grow, and is highly profitable if handled in the right way. In most private gardens there is always a good mint bed, which in the winter months does nothing. There is no reason at all why the whole of it should not be forced at once, and there would still be plenty left for stock purposes next season. The ideal way is to prepare for the forcing during the month of August by inserting cuttings of the mint in a moist situation. When they have become established, which will be in about a fortnight, the beds should be hoed twice a week and until the runners commence to cross the beds. When this is seen, all cultivation should cease. When the plants have flowered and the foliage has died down, cut all the stems off at ground level, and leave alone until the beginning of December. Now top-dress the beds with a light mulch of strawy litter to encourage the young green shoots to sprout. During the first week in January the plants may be lifted and either boxed or planted straight into borders under glass. Just spread the roots matted as they are evenly over the surface of the box or border, and cover over with 2ins. of fairly fine soil, and water in at once. No heat at all must be applied until the shoots are well above the surface of the soil. This is very important, for crooked, immature and diseased mint is the inevitable result of trying to force before active root action has commenced. When the

Digitized by Google

right time arrives, then put on 90° of heat and spray the mint foliage frequently during the day, giving a final damping down before closing the houses at night. When the young tender stems are about 3ins. in length, give a very slight top-dressing of nitrate of soda and water it in at once. This will give colour and luxuriance to the leaves.

The first cut may be made when the crop is 6ins. high, and bear in mind it should be cut, not pulled. Do not take any weak, spindly stems, for these will thicken out when the first cut has been taken. The mint should be bunched, tied and placed in luke warm water for an hour or two, when it will be found that the leaves have rearranged themselves nicely. A bunch consists of as much mint as can be comfortably held in between the fore finger and thumb. Tie the bunch low down so that the salesman may suitably display the contents. Before packing for market the bunches should be well drained, or they will heat up during the journey. Pack an even number of dozens of bunches in a box similar to that recommended for beans, advising your salesman when sent. Anything up to 15s. per dozen bunches will be returned, and you can cut the crop four times before throwing the roots out in preparation for tomatoes. Odd bunches, of course, should not be sent, and it rarely pays to send under one dozen bunches at a time, but a dozen and over are welcome in the market.

I have purposely not mentioned many other crops that might be grown and forced, such as seakale, rhubarb, mushrooms, for to have a little of everything is worse than useless commercially. Concentrate on one or two really profitable crops and stick to them until, in a very short time, your "mark" will become known on the market, and the stuff will sell on sight. Tomatoes, up to a point, are a paying crop, but the private cultivator must be very early with them, or he will clash with the Worthing and Channel Island stuff, to his serious disadvantage. Early English tomatoes will make 2s. 6d. per pound easily if well grown and of good colour. Kondine and Comet are two of the best kinds for market, which likes a medium-sized, highly coloured and smooth-skinned fruit. Here is a tip about tomato growing which has put thousands of pounds in the pockets of the Guernsey growers. It is fairly easy to grow tomato plants, but it is not so easy to get the first trusses of bloom to "set," despite the vigorous use of the rabbit's tail! Try starving the young plants just after they have been put into their permanent quarters. Keep them very dry. The best "setters" are those which look blue, thin and wiry, not the big, hefty, coarse-growing ones. The reason is that Nature, in the effort to preserve its species, hurriedly causes the half-starved tomato plant to throw a bloom which invariably "sets" rapidly and well. When this has been accomplished, then feed hard so that the first truss may be fed and the fruits properly developed, while at the same time the upper trusses are setting. After the fruit of the first truss has been picked and marketed, nip out the top of the plant (commonly called "stopping") and top-dress the border or pots, as the case may be. Give heavy applications of liquid manure. Unless there are large quantities grown it will not pay the grower to send to market after the price has dropped to 4d. per pound. Concentrate on getting those first two trusses well "set," for it is cheaper, and therefore more profitable to grow 100lb. of tomatoes at 2s. 6d. per pound than ten times that quantity at 2d. or 3d. per pound.

STRAWBERRIES

form one of the more highly paying crops which can easily be grown by the private gardener. Very few commercial houses indulge in them, for the simple reason that it would be impossible to give them the detailed and individual treatment so necessary to luxury crops pure and simple, so there is a clear market with a good demand.

Strawberry plants for forcing should be selected from healthy plants growing outside. Maiden runners are chosen about August, and are pegged into small pots *in situ*. When they have well rooted and are growing independently of the parent plant, the runner may be severed and the plants potted up into large 60's. For convenience it is usual to bring the batch along in cold frames near the forcing pits into which they will go when the right time arrives. Now the plants will require rather special treatment in both manuring and watering. They must never be allowed to get bone dry, or they will produce only blind flowers. Never use concentrated nitrogenous manures at this stage, or, again, only blind blossom will come. Bi-weekly applications of dilute liquid cow manure and soot will help enormously in the building up of the flowering crown, which must be fat and plump to ensure getting the best results. When the crown commences to show signs of activity, which will be about the last week in November, bring the plants into the forcing pits and give them a temperature of 60° to start.

Spray overhead frequently so long as the flower is not present. As soon as it is in full bloom, cease to spray, and ventilate freely on warm, sunny days. After the flowers have "set," raise the temperature and give a slight top-dressing of Clay's Fertiliser. Lightly sprinkle chaff or some other suitable material on the tops of the pots so that the fruits will not get splashed and gritty. It is a good plan to suspend the fruit trusses on to a forked stick so that air and light may surround the fruits.

Then comes rather a critical time with the plants, for they must have sufficient heat to keep them moving and the fruits swelling, at the same time they must have ample air, which must freely circulate among the plants. Now follows the most anxious time of all, the marketing.

Carefully cut the fruit with its stalk and place singly in the one pound punnets which the salesman will supply. Line the punnet with clean strawberry leaves and try to arrange the fruits so that they rest individually on a leaf. A little practice will soon make perfect, but it is advisable to practice with small potatoes or something similar at first. The punnets are packed in special "trays" supplied by the salesman and sent off to the market by passenger train. Prices returned may be anything from 10s. to a guinea per pound. If it can so be arranged that the fruit will be ripe by about Christmas-time or New Year's Day, or at any festival time, such as Whitsun or Easter, the price will be high. The luxury hotels are always on the look-out for something unique and are ready to pay well for it. The best variety to force is our old friend Royal Sovereign—it cannot be beaten for flavour, shape and hardiness.

NEW POTATOES

are so comparatively easy to force that one cannot help wondering why those with some glass do not utilise it more for this crop.

I have always preferred to force potatoes in large chrysanthemum pots, since the plants are so much more under control. But it is quite in order to plant them direct into the borders. New potatoes at Christmas and from then onwards to April will make without trouble anything from 1s. to 2s. 6d. per pound, and to take an average crop, the weight would pan out at about half a pound per plant.

The seed chosen should be well ripened and about the size of a hen's egg. It is better to sprout it on trays in a light, airy loft or shed. There may not be much in this from the point of view of earliness, but a sprouted seed potato grows right away as soon as planted, with no check of any kind, whereas a non-sprouted tuber has to wait in rather a wet, cold medium until growth commences. I prefer the waiting period to take place in the sheds. When the shoots are about half an inch in length the seed may be cut and planted at once about 4ins. in depth in the pots prepared. From the sized seed mentioned it will be possible to secure two nice "sets," each with two fine sprouts. Having planted and installed them under glass—either heated frames or greenhouse will do—thoroughly water in and leave alone for at least a week. It is fatal to overwater potatoes. As the growth advances feed once weekly with dilute liquid manure, and a mulch may be given round the tops of the pots of old and well rotted stable manure. Suspend long strings of coir fibre from end to end of the house 6ins. over the top of the pots so that the foliage will not become entangled. Maintain an equable temperature of 65° at night and 70° in the day. After the plants are full grown and the foliage commences to turn a little yellow, the crop is ready for lifting. If dirty, the tubers may be very carefully washed, but the very greatest care is necessary here, or the tender skins will become rubbed and the general appearance ruined for market purposes. Pack very carefully in non-returnable wooden boxes which will hold exactly 14lb. (the boxes are supplied by the salesmen) with a cushion of soft wood wool at the top and bottom of the package. There should be no movement of any kind inside the box after it has been packed.

Digitized by Google

The best forcing variety is Dargill Early. It is a nice white-fleshed kind and kidney shaped. The best prices are always obtained by kidney-shaped potatoes of a medium size. Do not make the mistake of waiting for the crop to become larger, for the lowest prices are always returned for the largest new potatoes, and you have the extra rail carriage in addition. The most profitable time to market the crop is January, February and March. Before I leave the subject of glasshouse crops let me say that all special stuff of this description should always be neatly packed up in small quantities. The packages sell more readily on the open market, for it is highly priced and prized, and as such has rather a limited market. If the grower does not do this, then the salesman does, and either charges you for the work or takes the benefit of it himself, returning to you the price your indifferent packing justified. Do not ruin the work of months, maybe, by not exercising care in packing and grading. Luxuries need luxurious packing, and it more than pays. SIDNEY P. WELLS.

INTERESTING PLANTS

IT is very welcome, to at least one reader of THE GARDEN, to find the Editor in a recent editorial championing certain plants for their *interest*, since most people are inclined to apologise for a plant whose decorative value is not its only claim to a place in the garden. Yet the beauty of a flower is no more an intrinsic quality than its association with folk-lore, legend or history, and we need not accuse ourselves of sentimentality or any falsification of feeling if we like a plant the more because it was praised by Parkinson, or because it has struck out a new line of adaptation to its surroundings, or even because it is fabulously difficult to grow.

It is tempting, with the lead given, to put in a further word for this not very popular kind of gardening, though we may have learnt to look upon the description "interesting" in catalogues as a forlorn bid for approval rather than a warm recommendation. The Editor shows how a tour of the garden may also be a tour of the world, and we might, if we cared to, make the expedition more complete by grouping together plants of one country so as to bring out their peculiar characteristics. Cassiope tetragona, Rubus arcticus and Loiseleuria procumbens would reproduce the wind-swept moorlands of the Arctic; cistus, lavender, rosemary and helianthemum the sun-baked maquis of the Mediterranean basin. A group of olearia, Veronica salicornioides, V. cupressoides and Raoulia australis might not evoke a very true picture of New Zealand, but it would bring out the oddity of the Antipodes where daisies grow into trees, veronicas imitate conifers or club-mosses, composites look like sheep and gentians are white.

If almost any Chilean shrubs are put together (with Tropæolum speciosum growing through them if your garden is north of the Trent), they will show that red and orange are the typical flower colours of their country.

We can travel through time as well as through space in the garden and recreate a piece of Elizabethan England with a box edging, crown imperials, a Damask rose bush, clove carnations, "melancholy gentlemen" (Hesperis tristis matronalis), gilded rosemary and many another plant described by Parkinson.

The Elizabethans seem to have had a taste for the monstrous and fantastic, which is perhaps characteristic of any period of exuberant intellectual vigour; it comes out clearly enough in their drama, and we can illustrate it in the garden with the rose plantain and the Plymouth strawberry (these still exist somewhere, but not in catalogues), the "frantick or foolish cowslippe," green primroses, striped roses and freaked gilliflowers.

The mediæval herb garden is easily reproduced, but it is frankly an intellectual curiosity, for most of the old herbs which have passed out of general cultivation have only the beauty of their names and the fragrance of romance to recommend them. An equally interesting but more decorative picture could be made of the doyens of the garden, the Provence rose, hollyhock, Madonna lily, marigold and purple iris, which are probably the oldest flowering plants in cultivation in western Europe. The old "apothecary's rose" (Rosa officinalis, a deep red Gallica) might also find a place for its fragrance and the rich colour that gave it so great a reputation, on the principle of sympathetic magic as a tonic and cordial, that it became the mediæval equivalent of pink pills for pale people, and a later age claimed to have found that its petals were peculiarly rich in iron. Moving forward through history we can recall the prosperity of the Dutch Republic with a piece of topiary and a few flamed and feathered tulips, of which Zomerschoon, Mr. Jacob tells us, is the oldest variety in cultivation. The moss rose, especially Oellet Panaché, striped pink and white, might stand for the Second Empire, and loves-lies-bleeding, though it is a very old garden plant, for a slightly faded Victorianism.

These are a few plants that we can use to illustrate impressionistically certain ideas. There are many others too numerous to mention, and, indeed, there is scarcely a plant in the garden but has some individual characteristic or some history attached to it, which, for those who care for such things, will bring it within the category of interesting plants, and will create that desire for possession. F. A. HAMPTON.

NOTES OF THE WEEK

RED HOT POKERS.

THE torch lilies or kniphofias are probably the most prominent flowers in the herbaceous borders as I write. They are decidedly early this year, after a hot and dry spell, lasting some eight weeks, and, last winter being a specially open one, they were not crippled in any way.

I have not seen many new varieties of kniphofia these last twelve years and this selection may seem rather old—but it is good and hardy. It includes rufa, typical of the red hot pokers, *i.e.*, bright yellow, tipped with red; Tuckii, a peculiar shade of red, fading off to yellow; caulescens, massive spikes of crimson and yellow; corallina, scarlet shading to a bright orange; nobilis, also massive and distinct in colouring; floribunda, a rich crimson; Saundersi, orange, shaded vermilion; grandiflora, crimson orange; the yellows, Lemon Queen, Chloris, Ophir, Goldelse, Obelesque and Lachesis.

Though the majority of kniphofias run about 3½ft. to 4ft. in height, it must be noted that there are real dwarfs and giants. Of the above, caulescens, Saundersi, nobilis and Ophir are tall and tower at the back of the border to some 6ft. On the other hand corallina, rufa and Goldelse are under 2ft. in height; while good plants for the border, I like them best in the rockery, where their stiffness and gaudy colouring adds a charm to the general appearance.

Lucky folks in the south find these plants quite hardy, but we in the north have to be careful in winter. Soaking, cold rains are more destructive than frost, but a covering of ashes and a well drained site keeps them safe during most winters. As the colours cannot be conveyed in words to readers, I urge them to note varieties when they see them at shows and in gardens, and then to buy as they decide afterwards; there are many more kinds than I have mentioned, but, at any rate, this selection was as good as any back in 1914.—CLYDESDALE.

ERICA CINEREA.

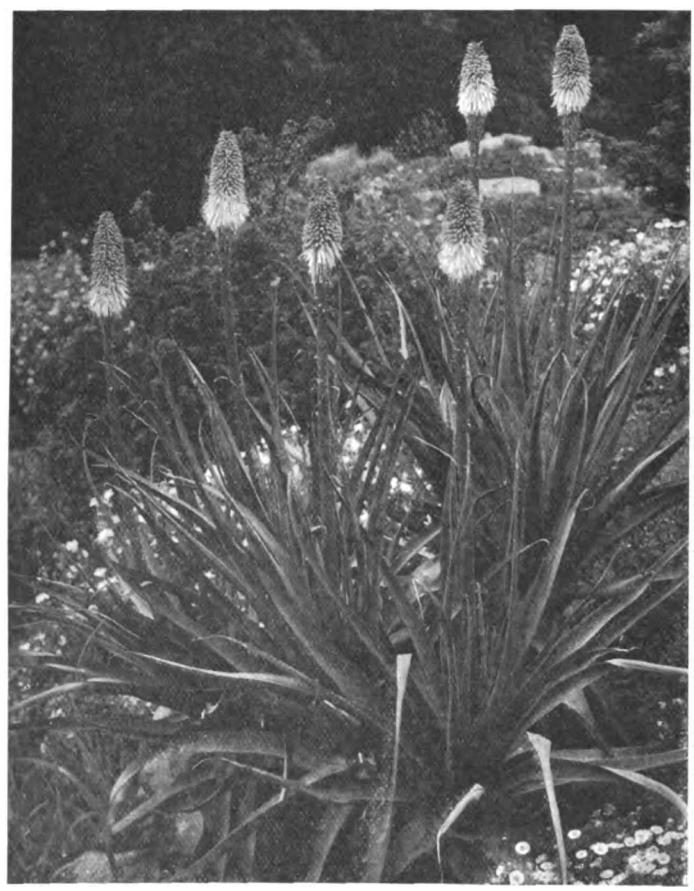
IN many respects our familiar bell heather and its varieties is one of the most useful and beautiful of its race. The earliest to come into flower of the summer-autumn species, E. cinerea will herald high summer in the heath garden with those billowy masses of purple, rosy red and white which, in wealth of colour and period of blooming, are not excelled by any other.

Always the first to show colour is E. c. coccinea, this being, perhaps, the most precious of the many forms of this variable species. With an almost prostrate habit, this very dwarf variety may at once be distinguished by the much darker, metallic green of its foliage, amid which the opening buds gleam like rubies, and so devoid of blue is the intense crimson of the full blown corollas that in some lights this colour approaches that scarlet hue which has earned for this delightful plant its varietal name and in the possession of which it is, I think, unique.

In E. c. atropurpurea the flowers are, again, a brighter, more crimson purple than in the type, and this charming form, while being considerably taller and bushier than the preceding, is not so bold and massive as, let us say, the excellent E. c. rosea. The latter will, even in a dry, poor soil, make rounded hummocks up to 2ft. in depth and covering a square yard or more, and these, from late June to September, will be enveloped with their splendid racemes of rosy crimson flowers. While I have no quarrel with E. cinerea for possessing that suggestion of magenta which an infusion of blue imparts to its generous blossoms, E. c. rosea, to retain its distinction, should be practically devoid of that shade, and in a good form it certainly is.

Fuller in tone than that of the average wild specimen is the sumptuous colour of the new variety, Victoria; Frances affords a note of distinction with its cerise bells; and among other late-comers both Apple Blossom, white with a wash of rose, and the very chaste pallida in pale shell pink, promise to be decided acquisitions. There is room for a better white E. cinerea than that which usually represents var. alba, the latter, in spite of the darker green foliage, somehow failing to reach one's expectations.

E. cinerea in all its forms is a plant for dry, well drained, sunny slopes, preferably stony. It is by no means always a peat plant in nature, preferring rather, as far as my observation goes, the light loam of rocky hillsides, leaving E. Tetralix and Calluna vulgaris to cover the damper, more peaty areas. In our heath garden it flourishes in a crumbling, sun-beaten shale, where it is often intensely hot, and there it seeds freely. A little leaf-mould may sometimes be used at planting time, but beyond this the plants never get any attention. Year after year they continue to yield their splendid masses of colour, and that at a season when flowers are often few. No heath carries on for such a long period without deterioration as this one, and these facts mean very much in these days, whether the gardener does his own work or has to engage others to do it for him.—A. T. JOHNSON.



KNIPHOFIA CAULESCENS, WITH MASSIVE SPIKES OF CRIMSON AND YELLOW.

ROSES FROM CUTTINGS: A COMMON ERROR.

VERY soon now those who wish to propagate roses will be turning their attention to securing and planting cuttings. It is, as we know, a simple operation in selecting shoots that are ripest, preferably those having a heel, and it is generally conceded that it is best to plant them in a bed to themselves in a sheltered quarter. What is not so generally recognised is that for the first twelve months or so no attempt should be made to interfere with them, and on this account they should be given not less than a minimum space of 12ins. between each cutting for dwarfs and more in the case of climbers. Too frequently this rule is honoured more in the breach than in the observance, the result being that before the autumn of the following year, the earliest time one can remove them with anything like safety, they become overcrowded. One is never far wrong in erring on the side of liberality when planting cuttings of roses.—W. F.

OLD FASHIONED BORDER FLOWERS.

DURING the last twenty-five years I have visited many gardens over Britain and I notice that what I might call old-fashioned border flowers are slowly but surely disappearing. Outside some fifty kinds which are common to all gardens over the country, each district has a certain further collection peculiar to that district alone (I refer to genera and species, not to varieties), but I am perfectly sure that where there are hundreds there once were thousands in the days when a large garden was filled with many kinds and before the cultivation of choice varieties of a certain few kinds became all the rage. It might be argued, of course, that some are no loss, but my reply is that the loss may be irretrievable and a future generation may be sorry for it. Is it not worth while trying to do something before the loss becomes greater? Personally, I suggest that large towns and institutions might run a "museum of plants," a border or borders filled with these old flowers, which gardeners, I am certain, will readily supply gratis. Head gardeners in our large towns are hard put to it to find money for their horticultural ideas and often, from necessity, fill long borders with repetitions of little value; perhaps they would welcome the suggestion and, stating that they were willing to receive old and uncommon plants, select—like the museum authorities—and plant. Extra work would be involved, but, if they only received during a certain week in autumn and another in spring, it might become possible. Of course, Sir, I only tentatively put all this before you and your readers; perhaps some will agree with me that it is worth while trying to do something, and discussion may indicate what is best.—H. A.

THE SCARLET LYCHNIS.

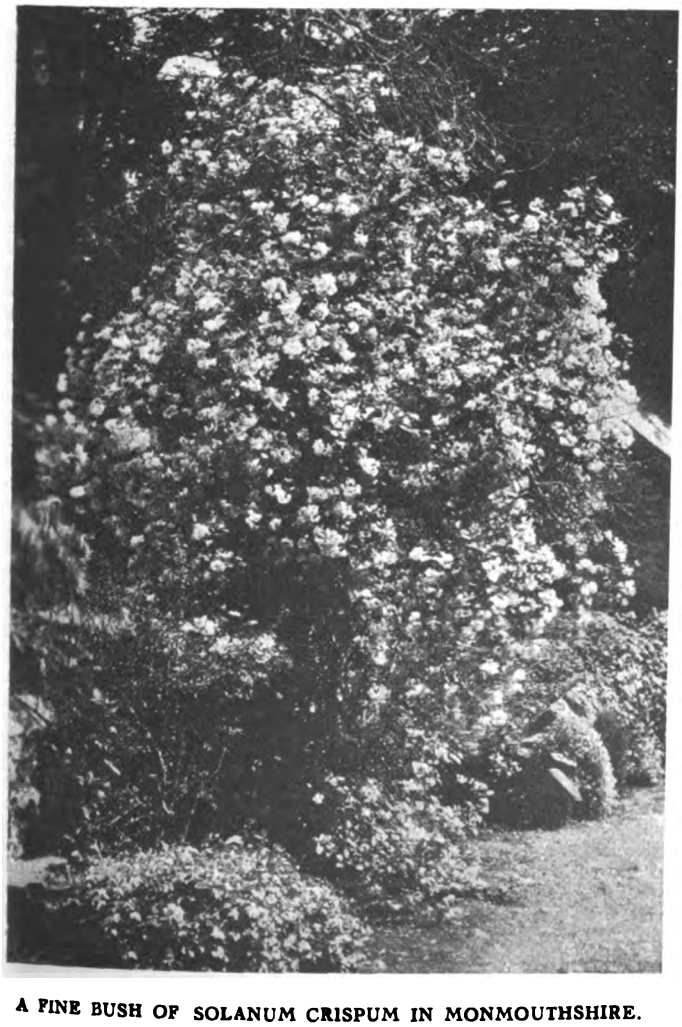
THE brilliant weather, which has lasted for some time, appears to have suited the scarlet lychnis, L. chalcedonica, well, and in the glowing sun its flowers have given us perhaps the most vivid colour in the herbaceous border. A small plant is of comparatively little effect, but one with a dozen or more flower stems surmounted by their large heads of bright scarlet flowers is ever acceptable in the borders in June, July and onwards. It is of tall stature in good soil, and may vary according to its position from 3ft. to 5ft. or even more. It has also, many of us consider, an additional interest, owing to the fact that it is one of the oldest plants from abroad which have been grown in British gardens. It is mentioned by Gerrard in 1596 and our venerated John Parkinson appears to have thought very highly of it, as, besides commending L. chalcedonica in his "Paradisus," he has chosen this flower to be immortalised in connection with his portrait, which appears in that monumental work, by carrying in his hand a head of the scarlet lychnis.

There are several varieties of L. chalcedonica, but some of these are much less plentiful than they were even as late as thirty or forty years ago. The single scarlet one, which can be raised from seeds, as well as by division and cuttings, holds its own well, but the double variety, with similarly coloured flowers, is much scarcer. Then there are the single white and double white varieties, L. c. album, and L. c. album plenum, with a rare flesh-coloured one, which I owe to the kindness of M. Hoog of Zwanenburg.

The scarcity of the double varieties is probably due to the comparative difficulty of their propagation. They are generally propagated by cuttings, and these should be from the flower stems cut into lengths before the flowers expand, early June being the best time, and struck under glass. Large plants of these and the singles may be increased also by careful division, but Mrs. Loudon says (and she was a generally reliable guide in such matters), that flowers from plants of L. chalcedonica, propagated by division, are generally smaller than where cuttings have been employed. This is rather curious, if correct. I have not raised the single white and flesh coloured varieties from seeds, but it is probably the case that only a proportion of the seedlings would come true to the parents. I know of no double flesh-coloured variety. Anxious as one often is to possess distinct and rare varieties of reliable and excellent border flowers, I think there can be no two opinions regarding these varieties of L. chalcedonica, and I venture to assert that none of the others can equal in value good plants of the old scarlet forms of this grand flower, both single and double.—S. ARNOTT.

SOLANUM CRISPUM IN THE SOUTH-WEST.

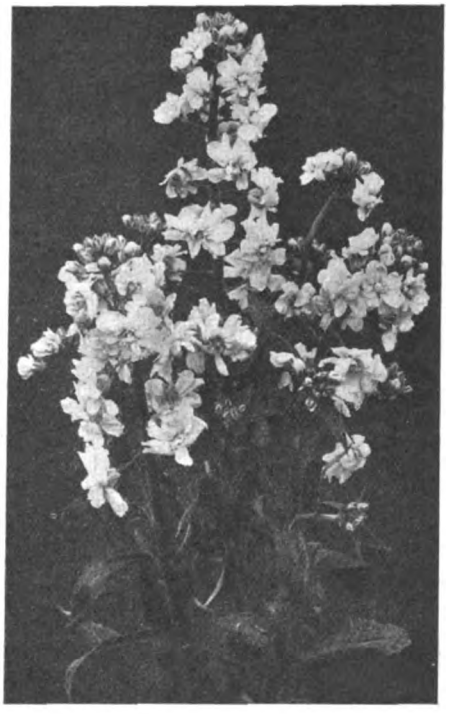
ALTHOUGH the potato tree, S. crispum, is more or less hardy it will not succeed so well in many counties as it does on the borders of Gloucestershire and Monmouthshire. In the illustration will be seen a plant covered with hundreds of flowers, a holly tree which had recently died making an excellent support for the shrub. Two years ago it was a small piece in a 3in. pot, and now it is about 14ft. high, and some 8ft. across, which proves how rapid is its growth when placed in a congenial position. The soil is rather poor, and the situation fairly open. It is readily increased from cuttings inserted in August, and from a healthy plant there is usually to be found a number of rooted pieces at or near the base. S. crispum is a native of Chili, from whence it was introduced about 1810. It is a beautiful plant in June and July, and those who are less fortunate in regard to climate, should give it a trial on a south wall, and prune it back in the spring; but where an old tree or building exists, it ought to be allowed to wander without let or hindrance, then it will be seen at its best, covered with thousands of its delicate bluish purple flowers, reminding one of the potato bloom in the kitchen garden or allotment.—T. W. B.



A FINE BUSH OF SOLANUM CRISPUM IN MONMOUTHSHIRE.

DOUBLE WHITE ROCKETS.

I SO seldom see the old double white rocket, Hesperis matronalis, now that one wonders whether there is not a danger of it being lost. It used to be a great favourite with Scotch florists forty or fifty years ago, who grew it to a degree of perfection not met with in the south. Though hardy, it is a plant which has its peculiarities and limitations, and this may, in a measure, explain why some



THE OLD-FASHIONED DOUBLE ROCKET.

have lost it. For instance, while many of our hardy plants do best when left to themselves for several years undisturbed, Hesperis matronalis depends for its existence and perpetuation on its being planted in fresh quarters every other year. It is advisable, too, not to rely solely on this method, but to work up a stock of young plants by propagating cuttings. Rockets like a rich soil in which good stable manure has been worked, but even in this they appear to be impatient, and if left too long before being removed to a new site often canker and die off. Though perennials, they can scarcely be placed in the same category as others from the fact that they cannot abide long in one place. This, I submit, is one of the reasons why this highly perfumed garden blossom is so rarely met with to-day. The old white rocket is a comparatively dwarf plant, bearing spikes of compact flowers and superior to the single annual forms.—LINDERS LEA.

HINTS FOR PRESERVING TOMATOES AND GRAPES.

AS soon as September comes the gardener has to be on the look-out for early frosts, when tomatoes are doomed. If he would ensure the development and ripening of all formed fruit, he should in August pick every tomato as soon as it shows signs of ripening. This will enable those left to swell more quickly. The gathered tomatoes should be wiped dry and stored in a tin. They must be looked over every other day. Tomatoes stored in this way ripen more quickly and surely than if placed in the sun or on a shelf. The box should be kept shut. This excellent recipe for preserving tomatoes for months was given to me by a Frenchwoman. She declared that they would keep if so treated from one season to another, but *that* I cannot vouch for! Perfectly healthy, well ripened tomatoes should be selected and placed in a glass or earthenware receptacle. They are then covered with a preservative consisting of eight parts of water, one part of vinegar and one part of

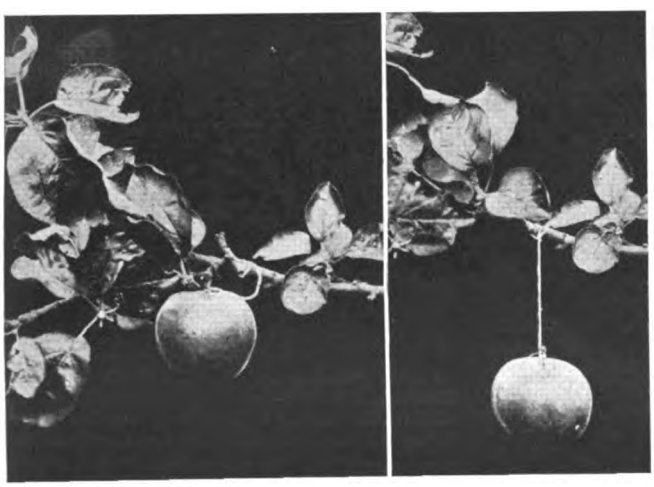
Digitized by Google

salt, which is covered with a thin layer of olive oil. An air-tight lid should cover the receptacle.

A Simple Method of Preserving Grapes.—I have kept dessert grapes throughout the winter by following this simple method: Select the finest bunches of perfectly ripe sound grapes. If there is one bruised or diseased grape, the whole bunch will perish. Fill wine bottles with water to which a little charcoal has been added. Cut the bunch off the vine *with a knife* (secateurs crush the stem and so ruin the bunch), leaving about 2ins. of stem above and below the bunch. Place one stem end into the bottle as far as it will go. The bottles should be kept in a dry, dark cupboard or, better still, a dry windowless wine cellar, and should be constantly looked over and a little fresh water added, as the stem in the bottle must *never* be out of water. Vine owners will appreciate having grapes at Christmas-time by following this recipe.—VICTORIA SLADE.

HOW TO PRESERVE CHOICE FRUITS.

IT is not always easy to decide the psychological moment that fruit has become quite ripe; it is much easier to pick a choice apple or pear long before it has attained the true state of ripeness that ensures long-keeping qualities. Of course, there is the orthodox method of ascertaining the moment when fruits are ripe by lifting the apple or pear gently upwards. Should the stalk remain firmly attached to the branch, it is a sign of unfitness for gathering, but a ripe fruit will part readily from the tree.



A GOOD METHOD OF PRESERVING CHOICE FRUITS.

There is a surer method of securing perfectly ripe fruit for storage, however, that anyone who has some really choice fruits can adopt, especially if exhibiting is in the grower's mind. This consists of tying one end of a short length of fine string to the stalk of the apple or pear and the other end to the branch to which the apple is attached some time before the fruit is expected to be ripe. Everyone knows that immediately the fruit becomes perfectly ripe it drops. When this happens to the apple that has been made secure to the tree the fruit is stopped in its downward course and is held suspended safely until the grower comes along to take care of it. In this way fruit can be preserved from bruises or scratches of any kind.—H. A. DAY.

THE USE OF CARBIDE CALCIUM GAS AGAINST GREEN FLY.

I HAVE found that quite the most effective way of freeing roses badly infested with green fly is by the use of carbide of calcium gas. The method of making the gas attack, which proved most successful, was on the following lines: A few small lumps of the carbide were enclosed in a number of little muslin bags. When rain seemed likely two or three bags were tied to each of the affected rose bushes. As soon as the bags became damp the generation of the carbide gas commenced, and this proved deadly to the aphides, which literally strewed the ground beneath in their thousands. The gas makes an unpleasant odour for a little while, but this soon passes away. In dry weather, when rain was out of the question, the muslin bags might be sprinkled with a little water to bring about the generation of the gas.—BOURNEMOUTH.

IRIDESCENT MOSSES.

EXCEPT to get rid of them as quickly as possible, gardeners, generally speaking, pay little attention to mosses. Those who wish to introduce a novel and extremely beautiful feature into the rock garden should certainly consider the iridescent mosses (Schistostega). These mosses are extremely small and, indeed, would hardly be noticed were it not for the wonderful gleams of iridescent colour which they exhibit when growing with vigour. The stones and patches of soil on which these mosses thrive appear to be sown with gold dust and a mixture of those indescribable hues found on the wings of many humming birds. Originally the iridescent mosses were thought to require a special kind of rock on which to grow, but it has now been proved that they will make themselves at home on sods of turf and masses of peat as well as on actual stone. All the schistostega do best in somewhat deep recesses away from strong light and exposure to actual rain. At all times the tiny plants must have a sufficient amount of moisture, as they are impatient of real dryness.

Some of the schistostegas are luminous at night; one which abounds in the caves of Central Europe known as S. osmundacea being remarkably so. For long it was thought that the glow was phosphorescent, but it is now known that the light arises from special spherical cells at the ends of the delicate branching threads which represent an early stage in the development of the moss plant. Each of these tiny globes, containing a few grains of chlorophyll, acts like the lenses of a cat's eye refracting the scanty light of the cavern where it strikes the globes and producing a bright disc on each as the result. By this means the light is concentrated on those positions where the chlorophyll is situated and, in spite of the dim illumination, the granules are able to discharge their special offices in an entirely efficient manner.—S. L. B.

OLD TIME USES FOR ROSE PETALS.

OUR grandmothers were in the habit of converting rose petals into all kinds of delightful fancies. How many people to-day think of making rose syrup?—and yet this forms a most delectable drink. A quantity of rose petals are collected and then chopped up and put on one side to dry. These are placed in a jar and covered with water, the whole being stood in a pan with more water in it. The petals are simmered until they are tender, and white sugar is added. The cooking process is continued until a syrup is formed. This is bright pink in colour, and a little, mixed either with hot or cold water, forms a delicious cordial.

Rose sugar was also a valued confection years ago. Here a jar was filled with alternate layers of white sugar and rose petals. The top of the jar was covered with paper well tied down. After a few weeks the sugar was separated from the rose petals, and this was found to be pleasantly flavoured with the fragrance of fresh roses. Often the sugar was served with whipped cream or spread on bread and butter.

Who thinks of making rose sandwiches nowadays? Here is the way to set about the business. Get some unsalted butter and cover this with rose petals for twenty-four hours. If the petals can be changed once, so much the better. A little while before cutting the sandwiches, bury the bread also in petals. Both the bread and the butter acquire a delicacy of flavour which cannot be described in mere words.

At one time rose beads, made as follows were much in favour. A large quantity of petals was closely chopped up and stewed in a pan until soft. The pulp was then pressed into a round shape, the hole in the centre of the bead being bored with a pin. When dry the beads were hard and black and, better still, delightfully perfumed. A few added to an ordinary string of beads gave an additional charm to the necklet.

Rose perfume, infinitely more powerful than any modern scents, was extracted by a simple home method. Into a jar half filled with the purest olive oil fresh petals were pressed. Every few days the oil was strained away from the petals and a new lot of petals added. In the end the oil was so highly scented that one drop was sufficient to perfume a handkerchief.—L. B.

SAXIFRAGA GUTHRIEANA.

SAXIFRAGA GUTHRIEANA shares the fate of so many forms of the type of S. umbrosa, the London pride, which do not appeal so strongly to the amateur grower of saxifrages as the true plants of the Aizoon or Kabschia sections of the genus. It is not a pure form of S. umbrosa, but is said to be the result of a cross between S. Andrewsii and S. Aizoon, the former itself being understood to be the result of a cross between S. umbrosa and S. Aizoon. It is, therefore, as we may expect, more nearly approaching S. Aizoon than the casual observer would imagine, and is, truly, a good saxifrage which may well find its way into the rock garden, although not commonly stocked by the nursery trade. In the ordinary conditions of the rock garden it is neater and smaller than S. Andrewsii, which is much more common; but, if given rich soil, it becomes much coarser and more nearly approaches in appearance this one of its parents. It is quite pretty when not too strongly grown, with its pink flowers and neat leaves. It is, however, a plant which derives its main interest from its having yielded a notable variety with variegated leaves. This must not be confounded with the variegated form of S. umbrosa, which is not so prettily variegated, is coarser, and not so constant in its variegation. S. Guthrieana variegata has its leaves most beautifully striped with various colours—white, yellow and pink showing distinctly on the green ground. But, unfortunately, there is a "fly in the ointment," and this takes the form of slow growth and instability in our gardens. Some ascribe this to wet seasons, but close observation has led me to form the opinion that birds are mainly responsible. They appear to have a penchant for tearing up the rosettes and carrying them off. The true place for S. G. variegata is, probably, the alpine house, and there it thrives well and increases reasonably if properly attended to. Increase of both forms is effected by division.—S. ARNOTT.

GLADIOLI AT WESTMINSTER

A BRILLIANT DISPLAY OF COLOUR AND BLOOM REPRESENTATIVE OF THE SEASON OF THE YEAR.

NOWHERE is the evidence more clearly seen of the passage of the seasons than in the garden. The inmates visibly change from day to day and as month follows month, so also do the different genera and species follow close on each other's heels. This was clearly shown in a rather striking fashion on the occasion of the fortnightly meeting of the Royal Horticultural Society on August 11th last. Quite the most brilliant display of the year was to be seen on entering the hall. The majority of the colours were of a bright nature, yet the varying tones blended exceedingly well. From the exhibits one would have concluded it to be a special gladiolus show, for certainly these flowers took pride of place. Nevertheless, another fortnight remains before they are earmarked as the special feature. On this occasion peaches, nectarines and apricots, listed as specialities, were conspicuous by their absence. Altogether, the collections staged were most representative of the season and the high quality of all the blooms is to be commended.

The gladiolus is, without doubt, one of the few flowers which has, in the past few years, gained a large measure of popularity and has found favour in thousands of gardens throughout the country. Its rise to fame has been almost sensational, and its extended popularity is fully merited. Probably no other flower possesses such a brilliancy and variety of colour, combined with elegance and gracefulness. More important, however, is its use in the garden, and here it is also equally good. It responds magnificently to good treatment, while it will flower well in practically all garden soils and provide a brilliant and lasting display in the border which will be rarely surpassed. Again, from the point of view of house decoration, the gladiolus is pre-eminent. When cut and placed in vases the spikes of the primulinus hybrids especially last for a long period in full bloom and in excellent condition. Their beauty, when the flowers are placed in a suitable setting, cannot fail to be appreciated

Messrs. Kelways again staged a very fine collection of their Langprim hybrids and large-flowered gladioli. The blooms of the individual varieties looked well in the vases, the size and form of the flowers being easily appreciated. Among the many excellent sorts we noted James W. Kelway, Pinkie, Langport Scarlet, Sea Mouse and Blue Jay.

Another magnificent collection, admirably set off by asparagus, was that put up by Messrs. Sutton and Sons. The varieties were massed together and although the resulting colour effect was good, yet the characteristics of the flowers were not clearly seen. Among the many excellent sorts were L'Immaculée, Fiery Knight, Princeps (an old variety), Baron Hulot and Duchess of York.

Messrs. R. H. Bath and Mr. Geo. G. Whitelegg, also contributed to the general array by their very fine collections, including many noted varieties. The colour of the blooms on both stands was good and showed the results of careful treatment during the growing period. Major Geo. Churcher also staged a number of interesting primulinus hybrids, while Mr. Alfred Edwards showed several sorts, such as Souvenir, Scarlet King, Psyche and Dorothy, and Messrs. Lowe and Gibson such varieties as Laetitia, Niobe and Maiden's Blush.

These excellent exhibits should do much to increase and extend the cultivation of this fine hardy border plant.

Roses were again represented by stands arranged by Messrs. Pemberton, Messrs. Chaplin Bros., and Messrs. Dickson. All the leading varieties were shown and appeared in fine condition.

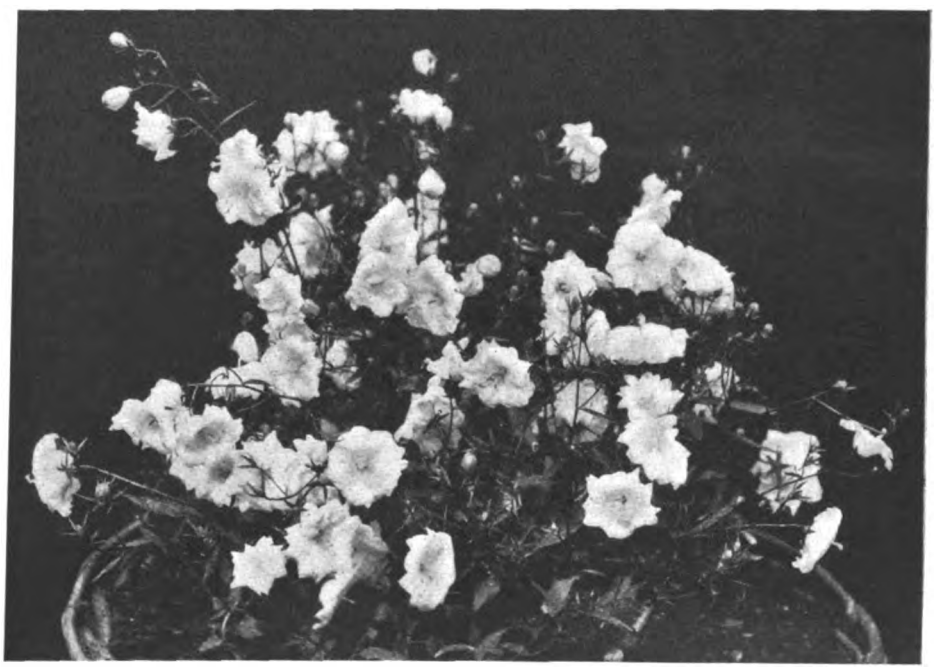
Mr. H. J. Jones once more excelled with his collection of phloxes, all in full bloom, and laid out in an oval, while Mr. Edwin Beckett, also staged a magnificent group, equally well grown.

A very fine collection of tomatoes in pots was staged by Messrs. Dobbie of Edinburgh. The plants all appeared in excellent health and carried heavy crops of fair sized fruit. Both the yellow and the red fruiting varieties were shown.

Herbaceous flowers, fruit, carnations and greenhouse plants completed the number of exhibits, and all contributed to the success of the show.

The alpines were few, but very interesting. Messrs. Reuthe showed a collection of minute, slow-growing shrubs—not the showiest nor the easiest of rock plants but beautiful, with the peculiar distinction of flowering plants which have adapted themselves to wind and storm. Myrtus nummularioides, a tiny, creeping myrtle from Patagonia, with leaves like a thyme, but typical flesh-coloured flowers and pink, waxy berries; Gaultheria antipoda var. adpressa and G. pyrolipha var. cuneata, wiry little shrubs a few inches high from the Alps of New Zealand; Dracocephalum Isabellæ, with stiff, rosemary-scented leaves and ample heads of powdered violet flowers; Pyrola rotundifolia, a rare native woodlander, whose waxy white flowers suggest a lily of the valley and are sweetly scented like Cyclamen europæum; Geranium cinereum album, a remarkably fine albino, not a washed out version of the type, but delicately veined with dark red; and Allium macranthum, a new garlic from China, with a loose head of drooping, reddish purple flowers suggesting pear drops—a handsome plant.

Messrs. Prichard showed a new saxifrage of their own raising, a cross between S. primuloides and S. Aizoon, conveniently named "S. Primulaize." From neat, leathery rosettes of London Pride it throws up a shower of starry deep magenta flowers on red stems. The interesting and striking colour should look well against a pale background. Gentiana septemfida is one of the best of the cluster-headed gentians, especially for the sharp contrast between the pale blue and inky black panels on the outside of the corolla. Of this a very fine seedling variety was shown, carrying its flower heads quite upright instead of flopping rather weakly like the type and with much larger flowers of a deeper, fuller blue. Leucophyta Brownii, an old bedding-out plant from Australia, that looks as though it were made of stiff white string, knotted here and there into flower buds, was also there in association with Convolvulus Mauretanicus, whose deep, lavender-blue trumpets have a rare luminous quality; it needs and is well worth the warmest and sunniest place in the garden. The former should make an interesting addition to the rock garden.



THE CHARMING CAMPANULA WARLEY ALBA, OF RATHER SPREADING HABIT.

Other exhibitors were as follows:

Messrs. Stark and Son, Fakenham, mixed herbaceous flowers; Messrs. Allwoods, carnations; Mr. C. Engelmann, carnations; Messrs. L. R. Russell, greenhouse plants; Messrs. Amos Perry, water lilies and herbaceous flowers; Messrs. K. and E. Hopkins, herbaceous flowers; Messrs. Stuart Low, carnations, greenhouse plants and figs in pots; Mr. Thomas Carlile, delphiniums; Messrs. Isaac House and Son, Scabiosa caucasica hybrids; Messrs. Cheals, dahlias; Messrs. Bunyard and Co., well fruited specimens of fruit trees in pots; Messrs. Laxton Bros., apples and the Veitchberry.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

GILIA CALIFORNICA.—This Californian representative of an interesting genus is a rather low, much branched shrub, carrying

Digitized by Google

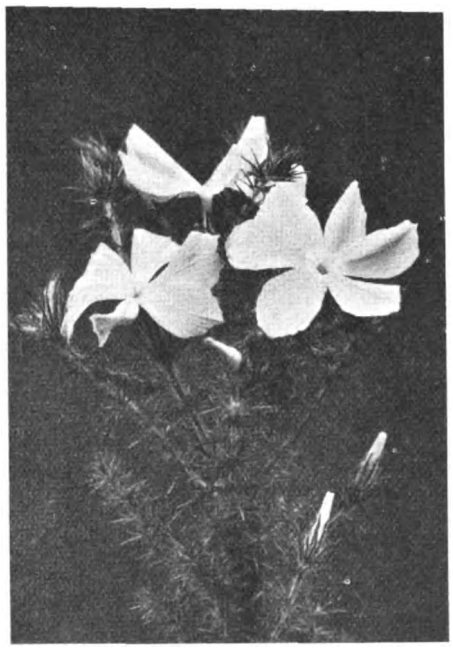
showy, rose coloured flowers. The plants shown were grown from seed sent from California and are, we understand, the only ones in this country. It is not hardy and requires the shelter of a cool house. The height reached is about one foot and the alternate leaves are deeply divided into numerous short segments and densely cover the stem. The flowers are about 1¼ins. across and are carried at the ends of the stems. Shown by Mr. T. Hay, London.

PHLOX MRS. H. B. MAY.—The plants are about 2ft. high and carry numerous trusses of medium-sized flowers of a clear pink colour, extending to the eye. The foliage is also good and sets off the flowers to advantage. It should prove a useful variety for massed colour effects in the border. Shown by Mr. H. J. Jones, Ryecroft Nurseries, Lewisham.

LILIUM BAKERIANUM.—The flowering stems of this species are almost 2ft. or so in height and carry a single, drooping, elegant flower, with petals of about 3ins. long and reflexed, and 3ins. across. The interior of the corolla is heavily speckled with maroon, while the base has the characteristic green of almost all lily flowers. The leaves are fairly long and narrow. It is an interesting species. Shown by Messrs. R. W. Wallace and Co., Tunbridge Wells.

SIDALCEA HIAWATHA.—A new variety which looks well in a clump, as it was exhibited. It reaches a height of 2½ft. to 3ft., and is very floriferous. The flowers, characteristic of the family, are about ¾in. across and of a rosy-mauve colour, with a white centre, out of which arises the stout staminal column. Shown by Messrs. Stark and Son, Fakenham.

SPHÆRALCEA FENDLERI (HASCOMBE'S VAR.). —Sprays of this shrubby globe mallow, adapted for the greenhouse, were shown



THE RARE GILIA CALIFORNICA.

carrying numerous rather small orange-coloured flowers. They are built up on the usual plan of the family. The foliage is of a dull green and forms a pleasant background to the flowers. Shown by Mr. Chas. J. Musgrave, Hascombe Place, Godalming.

CAMPANULA WARLEY ALBA. — This is a fairly old variety, which was originally raised at Warley Place. It is a charming little plant of a rather spreading and procumbent habit, carrying numerous pure white semi-double campanulate flowers, about ¾in. across. The foliage is also rather ornamental and shows the heterophylly so often found in many species of this genus. It should prove ideal for corners in the rockery or as an edging. Shown by Messrs. M. Prichard and Sons.

RHODODENDRON SEROTINUM.—This species from western China is a member of the Fortunei series, which embraces the majority of our late-flowering rhododendrons. The flowers of this species are of much the same general shape and form as R. auriculatum, but on a smaller scale. They are fairly large and more or less flatly bell-shaped, and six to seven occur in a truss. The flowers have a slight fragrance. The leaves are shorter and more rounded at the tips than is the case with R. auriculatum. Shown by the Director, Royal Botanic Gardens, Kew.

ORCHIDS.

BRASSO-CATTLEYA CORRIENTES (B.-c. Ilene × C. Hardyana).—This elegant hybrid was raised in the collection of Dr. M. Lacroze, "Bryndir," Roehampton Lane, Putney, with whom it first flowered last year. The present example bore a very large flower, having the petals arranged in upstanding habit, while the broadly developed labellum had the margin crisped and fringed. Sepals and petals of uniform rosy-mauve colour, the labellum much darker on the marginal zone, a bright yellow area on each of the side lobes formed conspicuous features. This is a promising hybrid, and when fully matured will doubtless gain a higher award. Award of merit. Shown by Dr. Lacroze (orchid grower, Mr. A. Taylor).

CORRESPONDENCE

HYDRANGEA SCANDENS.

SIR,—Some months ago I saw a letter from Sir Herbert Maxwell recommending this to be grown against a house. For some years I tried it on a tree, but moved it, as it was not doing well, to my house, where it has done splendidly and is over 20ft. high and continues to spread.—H. G. HAWKER, *Devon.*

ALUM FOR SLUGS.

SIR,—In following Mr. A. D. Richardson's instructions for using alum against slugs (THE GARDEN, July 4th), we have discovered its use in another direction. A young standard damson having gone off with "the yellows" in mysterious fashion, my gardener, having some of the solution of alum left over, watered the ground round the stem with it. To his surprise a number of wire worms, some twenty to thirty, quickly made their way to the surface and were captured and destroyed. He described them as looking rather "faint like" on emerging from the ground. I wonder if the alum will destroy leather jacket grubs equally well! We find it is they, and not slugs, that eat off the endive, and they can be secured with the finger, just below the soil. Anyhow, my sincere thanks to Mr. Richardson.—ALICE MARTINEAU.

AN INVITATION.

SIR,—In the cause of Anglo-American friendship, I think it may interest your readers to know what a very real part in it garden-lovers may play.

For the past three years, through the kindness of many friends of the English-Speaking Union, the Garden Committee has been able to arrange for visitors who belong to the Garden Club of America (a large organisation which has done much to promote a wide love of horticulture) to see a number of private gardens, both large and small, in England. These visits have given so much delight that the Garden Club of America wishes now to return the compliment, and they would like to give the English garden-lovers visiting their country specially arranged facilities for seeing some of the beautiful gardens in the United States.

Interesting and lovely gardens in the Eastern States, such as those on Long Island, along the Hudson River, in Westchester, Connecticut, New Jersey and Philadelphia, will be shown, and a letter of introduction from our Committee will ensure that convenient arrangements will be kindly made for the English visitors. Applications for such letters of introduction should be made to me. — ISABEL MARGESSON, *Chairman of the Garden Committee of the English-Speaking Union, Charing Cross, S.W.1.*

IRIS TINGITANA.

SIR,—*Re* B. K. G. and Iris Tingitana in THE GARDEN of February 21st, I have had two clumps of this iris, with about fifty bulbs in each, growing in the open—one in full sun and one in partial shade, for the past nine years. With the advantage over England of ten degrees of latitude, and a mean temperature last year of 57deg. Fahr., the plants make great growth and increase rapidly at the bulb. They flower here in July-August. In 1921 there was one bloom, in 1922 there was one, in 1923 none, and in 1924 two; this year I see no signs of any. Two miles away, under similar conditions, they flower profusely, and some fifty bulbs, given away when dividing the roots two years ago, produced in Blenheim, about twenty miles away, over forty blooms last winter.

Calthrop, in "The Charm of Gardens," says it is a question of "whom the flowers love." Dr. Lloyd Praeger, in THE GARDEN of January 10th, says, more with regard to growing than blooming, "if they won't, they won't." In my humble opinion it is unadulterated cussedness. — A. R., *Queen Charlotte Sound, New Zealand.*

THE YELLOW SWEET PEA.

SIR,—Your correspondent's letter referring to the search for the elusive yellow sweet pea fails to record, to my mind, a most important fact. That is, there is no one flower yet known which gives us the three primary colours—blue, yellow and red—and I often wonder if we are up against the proverbial brick wall in attempting to produce these colours in one flower and so, I might add, thwart nature. My knowledge of flowers is somewhat limited, I must admit, but perhaps your readers can inform me of a flowering plant giving us the three *true* colours (if there be one). At the moment a perfect red and a blue hyacinth occurs to me, but we have, as yet, no true yellow (the buttercup yellow). We have red and yellow roses, but where are the blue ones? It somehow would seem uncanny to have a blue rose! Poppies are gorgeous in their yellows and reds. I have yet to see a blue one. Other instances will occur to the reader. I agree with Ed. Cahen in his article, "Blue in the Garden," when he says that "the blue sweet pea has yet to appear," but we are nearer to that than the yellow sweet pea, which I venture to state will never be found.—CEDRIC C. UNDERHILL.

WEEDS—GARDEN TRAMPS

MAN plants a garden saying, "Here I will have grass, here flowers, there rose trees, yonder apples, in the shadow of the plums the raspberries will grow, on that barren piece of land Jerusalem artichokes, on this sunny wall a nectarine will blossom even if it has no fruit, these stones shall make a warm, well drained pocket where a gentian shall tell me what blueness is, and here and there shall be lines of desert called paths." Thus the gardener orders, and in his mind he sees the plants obedient to his will; in this patch man becomes a great lord, but he is not as great as he would wish to be, for he cannot command when the sun is to shine or the clouds to drop rain. Such things, however, belong to a far away dominion, so man does not fret at the rival lordship. But unfortunately for his complete peace of mind, there are some plants here on earth who do not bow in obedience to his will. These are the tramps who enter into his demesne by his gate, even on his own feet, blow over his hedges, are carried by birds and grow into what he is pleased to call weeds.

Man orders, "Here I will plant grass seed and after a few years I shall have a fine lawn, green all the year, soft all the year, reminding me of spring in the midst of winter and of coolness in the heat of summer. Here are to be no reds and blues and yellows, but green alone, that universal expression of life." But if grass grows on a path or springs up between the peas or beetroots, the gardener seizes the little plants in wrath and annoyance, saying, "You are a weed, you must die."

Ask a friend what a weed is and the answer may be, "Well, of course, dandelion, chickweed, squitch-grass, groundsel. Dash it, everybody knows what a weed is." But what at the end of April or the beginning of May is more beautiful than a bank starred—or is it sunned?—by dandelions? Before we adopted the French name (*dent de lion*, lion's tooth) did the Anglo-Saxons call it sunflower, for that should be its name in England. Sometimes a careless farmer allows a whole meadow to be overtaken by dandelions; then when the sun shines what a sight it is, rich, glowing, calling aloud for joy and gaiety. If that bad farmer continues in his lazy ways, that field may turn into a soft grey mist of dandelion clocks whose winged seeds rise up on little puffs of wind and, floating softly and gently in the air of June, may find a temporary home upon your sleeve or in your hair.

What are weeds, indeed, but just plants that domineering man says may not grow in *special* places in his garden. Notice, he does not always forbid them his garden, but forbids them freedom to choose where they would grow.

A man once left his garden for a year. When he returned he found great tussocks of squitch-grass growing among his strawberries and wisps of squitch had even crept up the damp darkness of his box hedge and were growing out at the top. Where potatoes had been planted the year before there was the finest bed of Shirley poppies he had ever seen, foxgloves were pushing their hairy stalks up among his black currants, one winding path was a solid mass of forget-me-nots. The path wandered like a blue river between beds where sow thistles and lupins were in competition and where the long fingers of the grass were pushing at the leaves of polyanthus and flowering pyrethrum. The tiny spaces between his flagstones were gay with baby lupin plants. So the man started to fight the weeds, forget-me-nots, Shirley poppies, foxgloves, lupins. Man had ordered that the paths should be brown and plantless, so with a tiny regret he rooted up the blue flowers on the paths, but he watered with care those that were growing in the particular beds to which he had allotted them.

If only plants could read, the gardener would save much time by putting up a little notice, "Plants are requested to keep off the paths." Then the man transplanted some of the foxgloves to shady places where they would willingly grow, but many he had to root up and throw away. Some of the baby lupins he put in a nursery bed, but most of them died from poisoning by a weed-killer.

There are people who announce that there is not a single weed in their gardens—they are efficient but too hard. All gardens are filled with slaves and prisoners, well fed, well cared for, fat and flourishing, but still prisoners, they may eat, they may drink, they may marry and have children, but the gardener lord commands, "Here you must dwell! Your home may be on the mountains, but I choose that you live here in the valley. You have come from a warm, moist climate, but I insist that you stay here where it is temperate and dry. I will be very kind to you, but do not forget you are my slave." Plants, earth's supreme philosophers, make the best of their chances and out of their slavery make gaiety for their masters.

Now, the weed is a free lance, a tramp who says "Think I'll stay here," and unless the gardener turns him out, not once, but perhaps many times, he does stay. The really human garden should have a few weeds, a few individuals who have chosen to live in the garden, who honour a particular man by their presence. If only the gardener can soften his heart a little he may find pleasure in these weeds. Weeks before any slave plant has shown its blue or yellow, a little plant of purple nettle may hold up its square stalk with bunches of purple blossom good in shape and colour; then in a sheltered corner under a hedge a single dandelion may laugh at you from out its golden face just when all your friends are grousing about the lateness of the spring. The tough deep root of the dandelion has been quietly storing up energy for this early spring display. Gardener, do not cut off his brave head, or at least wait until he is too tired to laugh any more, but greet as a friend this little English sunflower whose ancestor must surely have been the sun in the sky.

Early, too, are the tiny white flowers of the chickweed, delicate flowers growing among delicate leaves. Allow just one plant to grow somewhere.

The groundsel is such a plucky weed that it compels admiration. It knows so well its end is to produce seed, it is so filled with the passion for posterity! If it cannot grow tall and blossom, it is content to grow an inch or two and produce a bushy little plant with a couple of flowers. If it is uprooted, it does not immediately lie down and die like chickweed, but twists one or two roots downwards into the earth, turns its growing point upwards to the light, and in the twinkling of an eye the buds have blossomed into flowers and the flowers have become seeds ready to fly away on their mission.

It is just this sense of choice, of freedom, that makes a plant that has seeded itself so much more delightful than one which has been ordered into a definite place, has been what the gardener calls planted. These plants are willing guests, and can be met as man to man not as master to slave. The lupin that seeded itself at the foot of the morello cherry need not be regarded as an interloper to be torn up, but as a guest to be encouraged. The Shirley poppy that decided to grow on a potato ridge had leaves 10ins. long and grew into a fine big plant which continued to blossom for a long time, for it was content in the place it had chosen for itself.

A tramp called greater celandine made a camp in a corner behind some globe artichokes. The gardener left it because the leaves were such a beautiful shape that he didn't think it could be a weed. But by the time he did learn its lowly origin he had grown to like the plant in the corner, and year after year allowed its children to keep their place, checking them a little, as it was not a plant that wanted to spread unduly. The gardener finally took a pride in the plant with the curiously cut leaves whose edges turn up like a saucer and which bears transient yellow flowers with lovely crumpled leaves. If by chance a leaf was broken, it instantaneously produced a bright orange juice and thus held out the hope of a speedy cure in case of jaundice. Here was a weed pleasant to look at, modest in behaviour and ready to help in time of need.

There are two weeds, squitch-grass and stinging nettle, which seem to have no virtues and of which not a single plant can be encouraged, but these plants are not merely irresponsible, happy-go-lucky tramps, but belong to the defiant criminal class, and yet, on still further thought, tussocks of squitch-grass make excellent places for robins' nests and on the leaves of the nettle live the masses of velvety black squirming caterpillars which produce those wonderful peacock butterflies.

"Now is the time to keep the hoe going," says the garden manual, but if you would have some friends in your garden, do not keep it going too well. O. A. MERRITT HAWKE.

SIMPLE GARDENING

LAWNS IN AUTUMN.

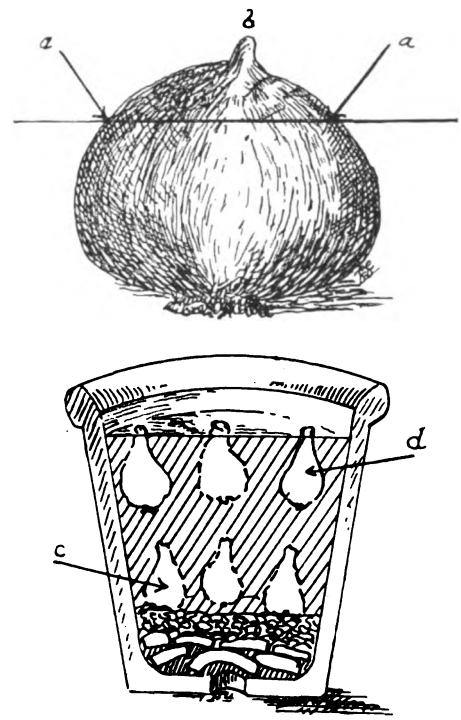
NO doubt many small lawns were badly worn during the recent spell of hot weather. When constantly used such lawns must suffer more or less according to the character of the turf itself and the under layer of soil. In the case of a sandy soil, the surface gives way, is "kicked up" if games are played on it; where stiff soils obtain the surface becomes very hard and grasses die off above soil level but are sound enough below it. A lawn of this kind, when rainy weather comes, soon improves and the new grass is of a finer quality, thus making a very neat lawn during the autumn and early winter months. After a wet summer these lawns often produce coarse grasses. The sandy lawn requires much more care after a hot spell of weather. There is always a little unevenness of surface to make good, and this is best accomplished by mixing some good loam (two-thirds) and leaf-soil (one-third) together after passing both kinds through a three-quarter inch mesh sieve. About two bushels per square rod should be applied, then 1 oz. of bonemeal per square yard. Scatter the ingredients evenly; roll if the weather be dry, then water once through a fine-rosed watering-can. In this simple way a town or suburban lawn, having done good service during the summer, will be quite fresh-looking by mid-September and look well throughout the winter without any applications of unsightly-looking organic manures. Where there is a strong-growing grass, it is good policy to continue the use of the mowing machine well into the autumn. If not frequently cut the grass gets coarser.

THE SPRING DISPLAY OF ANNUALS.

During the month of August and the first half of September seeds of many kinds of annuals may be sown to provide a very early display of flowers in pots in the greenhouse and also in the open border. At the time referred to there are not many flowers in a garden except those of bulbs. The first seeds to sow are those of Silene pendula compacta. It is not necessary to sow in boxes, though this may be done if more convenient. I prefer a fine open border where the seeds may be sown broadcast very thinly. In due course the resultant seedlings should be transplanted in their flowering quarters. This plant is excellent for filling small borders and for edgings and carpet plants. Seeds of Shirley poppies should be sown in the border where the resultant plants are to flower. The seeds are small, so do not be tempted to sow them very thickly. Cover them lightly with fine soil and be sure that the soil is kept free from weeds. Before the young plants get weakened by overcrowding, thin them to 4ins. apart; the result should be a wealth of blossom in due course. Sow the seeds in two batches in August and mid-September. At the latter date sow Clarkia elegans and Marigold Orange King. The young plants are to be flowered in pots; those of the former thinned out but not transplanted, those of the latter may be. The clarkia and mignonette seeds are best sown in good compost in 3in. pots, and, as suggested, the resultant seedlings should be thinned out and the others re-potted into 6in. pots early in October, three plants to a pot being enough. Throughout the winter a shelf in a greenhouse will be an ideal position for the plants.

POTTING THE EARLY BULBS.

The early bulbs will soon be available in great quantity. We generally look forward to the earliest flowers as we do to flowers in the border and apple blossom in the orchard in the spring. The bulbs vary considerably in size; the largest are not always the best; a good bulb must be firm and contain a well formed embryo spike of flowers.



Narcissi, tulips and Roman or French hyacinths are the first bulbs to claim attention, and for these the same kind of compost will answer. Extra fine flowers may be grown without the aid of manures; if any be used it should be well rotted and placed in the bottom of the pot. Manure water will be helpful when the flower stems appear, but artificial manures should not be used in the soil. Rotted fibrous turf, leaf-soil and sand form an ideal potting compost. Pots that have been in use before, but washed and dried, are the best for growing bulbs in. Tulips and hyacinths should be potted as shown in the sketch, the soil level being at *a*, *a*, the crown of the plant *b*, being just clear. Where it is desirable to grow as many flowers as possible in a small pot and the bulbs are large, several may be placed as shown at *c*, and others as shown at *d*; all will flower at the same time. Water the newly potted bulbs before plunging the pots in sand or leaf-soil.

FEEDING PLANTS.

As the autumn comes the weather is colder, especially at night, and the root action of plants is, to a great extent, arrested. But the pots of many plants are filled with roots and there is not any nutriment remaining in the soil to maintain the normal health of the plants, and a judicious application of some reliable stimulant will prove beneficial. The most reliable stimulants are those of a cool nature. We have now to deal with such kinds of plants as zonal pelargoniums, salvias, chrysanthemums, bouvardias, carnations and berried solanums, also the earliest batches of cinerarias and primulas. There are other kinds, namely, azaleas, rhododendrons, genistas, etc., that have filled their pots with roots. We call such plants hard-wooded, and their roots are fine and fibrous. The autumn is not the time to apply manures of any kind, although the pots are well filled with roots. If we feed them now the result would be, probably, bud-dropping in the spring directly the plants are subjected to a little forcing heat. No, clear water only must be applied, leaving the feeding of the plants to next year after they have flowered and are making new growth, and here again the feeding should be confined to such plants as are not being re-potted. The application of stimulants to others should be given before the plants are placed under glass and again after they have been at least one week under it. It is wise to apply weaker doses now than before housing, and cease to give any when the blooms are half developed.

GARDEN RUBBISH: HOW TO DISPOSE OF IT.

It does not matter how small the garden is, some rubbish will be found at this season of the year. In the country there need not be any difficulty in disposing of it, as its treatment can be carried out at some distance from the dwelling-house, but in a small town or suburban garden it is quite a different matter. Select a place private and as far away from any dwelling-house as is convenient, dig a hole in the ground large enough to contain at least two-thirds of the refuse below the surface. As the refuse—leaves, stalks, grass, weeds, etc.—is placed in the hole sprinkle lime on one layer and a small quantity of soil, and salt on the next layer without any soil, and so on. The one-third portion should be similarly treated but entirely covered with soil taken out to form the hole and so placed as to form a cone over the whole. There will not be any offensive smell from the heap and next spring the whole mass will be in a fit state to use as manure in the vegetable garden. Where the garden is a more extensive one and more rubbish will be collected, the whole of it may be treated in a heap above ground in a suitable place. GEORGE GARNER.

BULB PLANTING

THE bulb season is again with us, with the attendant spectre of winter to follow. We begin to think of spring again and so another year passes: we grow older—the "we" is not editorial, but general. It is always as well on a solemn occasion like a Bulb Number to begin with a platitude or two, it promotes a feeling of confidence.

Bulb planting is not so easy as it looks. By bulb planting I do not mean the adornment of beds when every bulb is planted in mathematical fashion, nor forcing bulbs nor bulbs planted in an odd corner of the garden for cutting purposes, but that planting where we try to ape Nature and pretend to ourselves that no human had a hand in the making of this mat of crocuses or this drift of daffodils.

At the Col de Lauteret this year I gazed upon an enormous patch of wild pheasant's eye narcissus, and came to the conclusion that most of the narcissus drifts in this country, although pleasant to look upon, were not natural. They are so planted that your attention is forced. In Nature you rarely see them in the mass formation so commonly used in this country, and when you do the result is usually more striking than beautiful. They wander about the alpine meadows in skirmishing order rather than in solid phalanxes. Many people, no doubt, admire the foliage of bulbs in general and narcissi in particular. I, personally, do not. Solid fountains of spear-shaped leaves do not interest me unless they are plentifully sprinkled with flowers, and to my mind a mass of green spears is the great drawback of solid drifts of daffodils. It is not so bad in early spring when you have the excitement of the flowering season in front of you, but once the flowers are faded and passed, the sight appears to me to be dull and dowdy.

NOTE HOW THE FLOWERS HERE DO NOT LOSE THEIR INDIVIDUALITY BY TOO CLOSE GROUPING AND PLANTING.

Of course these solid masses are often a variant of the original plan. The bulbs increase in course of time and frequently are not broken up and replanted, which is also a reason for lack of bloom. A method which does away with this close feeling of solidity is to plant your bulbs in such a way that the drift tails away. In Nature most flowers act as a column of troops on the march. You first come upon a few scouts slowly pushing their way forward into new or doubtful territory. Then comes the advance guard, the main body with their attendant flankers, the rearguard, and, finally, a few late stragglers. So it ought to be when daffodils are planted in drifts. It saves hardness of line and an abrupt beginning and end. I think it is universally recognised that the daffodil from its nature is essentially a plant for a wild garden, and so particular care should be taken about its planting. The modern daffodil is a product of the hybridiser, and so it is, perhaps, unwise to carry the parallel of a wild plant too far, but natural grouping is a real necessity. The bluebell is one of the few plants which grow wild in such profusion that they refuse to allow any other plant in their particular domain. Another method of avoiding monotony of colour and atmosphere in a drift of daffodils is to plant a proportion of another flower along with the daffodils, always allowing the daffodil the higher percentage. One of the best mixtures I have seen is daffodils and muscari, for the yellow takes away something of the hardness of the blue and the blue part of the monotony of the yellow.

It is difficult to give any detailed suggestions for planting, as each individual case has to be judged on its own merits, but perhaps I have said enough to show that drift planting cannot be rushed.

BULBS AND TUBERS FOR THE ROCK GARDEN

WITH A VIEW TO BRIGHTENING THE ROCK GARDEN IN THE SPRING MONTHS, BEFORE OTHER INMATES HAVE SHAKEN OFF THEIR WINTER SLEEP, A FEW OF THE UNDERMENTIONED SUBJECTS SHOULD BE TRIED.

MANY of the smaller growing bulbous plants are invaluable for the rock garden, and they can be planted any time now up to the end of October. But the sooner they are in the ground the better, as the spring display of flowers depends on the amount of root action produced before the winter commences. In association with low-growing plants, like the aubrietias, phloxes and other similar subjects, they will provide a charming display during the early spring months, while with a judicious selection of bulbs the season may be prolonged well into the summer months.

Among the earliest in flower in the spring are the chionodoxas, commonly known under the name of "Glory of the Snow." They form a small genus of two or three species, natives of the mountains of Crete and Asia Minor, where they flower in profusion amid the melting snow. They are quite hardy, and when left to themselves increase freely by means of seeds and offsets, soon forming large masses which are very effective on the banks of the rock garden. C. Luciliæ has flowers of a brilliant blue with a clear white centre, while there are also pure white and rose coloured varieties of it. C. sardensis is one of the best, with gentian blue flowers, a little later in flower than the above. Similar to C. Luciliæ and later in flower is C. Boissieri.

THE SPRING SNOWFLAKE, ONE OF THE EARLIEST AND MOST BEAUTIFUL OF SPRING FLOWERS.

Many of the crocuses may be recommended for massing in suitable positions in the rock garden and as the foliage is not coarse and also dies off early, it does not affect the display of bloom produced from the plants among which the corms are planted. Of these, C. Sieberi is a charming species from Crete, with soft lavender-blue flowers, having a bronzy yellow base. C. biflorus, the "Scotch crocus," has the outer segments feathered blue, while the inner segments are snowy white. Another good one is C. Imperati, with pale violet inner petals and fawn outer ones, more or less feathered violet to black. One of the best to naturalise is C. Tomasinianus, with pale lavender flowers. There are numerous other kinds equally suitable for this purpose and all are worth trying.

The erythroniums are beautiful low-growing woodland plants, generally with two more or less marbled or barred leaves, and slender stems bearing from one to several nodding flowers of various shades of colour. They like a cool, shady spot in the rock garden, and a loamy soil rich in leaf mould. Deep planting is advisable, for the plants cannot endure drought while in growth. The European E. Dens-canis is one of the best known, and there are many beautiful varieties, from white to rose and purple. From North America we get many handsome kinds, among which are E. americanum and E. grandiflorum, with yellow flowers; E. californicum (syn. giganteum), with delicate pale chrome yellow flowers, having orange markings in the centre; E. Hendersonii, one of the most distinct, with purple centred pale lilac flowers and E. revolutum, ranging in colour from creamy white to the bright rose coloured E. revolutum var. Johnsonii.

THE CHIONODOXAS SO APTLY NAMED "GLORY OF THE SNOW."

The golden blossoms of the winter aconite (eranthis) are very beautiful, produced among frills of emerald green foliage in early spring. The best known is E. hyemalis, so often met with growing under trees and in moist situations. E. cilicica comes from Asia Minor, with larger flowers and more finely cut foliage. A hybrid between these two species is E. Tubergeni, with larger flowers of a deep primrose yellow colour. Of the many bulbous plants that one can grow in the rock garden, there is none that appeals more strongly to the average garden lover than a patch of snowdrops, and it is certainly one of the first favourites of spring. There are numerous kinds, one of the best and most graceful being our

Digitized by Google

native G. nivalis. G. Elwesii is a distinct and beautiful species from Asia Minor, with large, snowy white flowers, the inner segments of which are marked with green. G. Fosteri is also from the same region, with broad, glossy green leaves and white flowers. The giant Crimean snowdrop (G. plicatus) is a handsome kind, with broad foliage and large flowers. After the foliage of the snowdrops has died down the bare places may be sown with annuals.

The iris family contain many beautiful bulbous plants that may be largely used for planting in sheltered nooks in the rockery, where the flowers would get a little shelter from bad weather when in flower. One of the earliest in bloom is the Algerian scorpion iris (I. alata), a pretty winter-flowering kind with arching green leaves and lavender blue flowers. In February, also, the violet scented iris (I. reticulata) produces its violet coloured, sweetly scented flowers. There are several forms of this, one of the best being I. r. var. histrioides major, with large flowers varying from purple blue to bright blue, and white spots on the falls, and a narrow orange crest. I. orchioides has bright golden yellow flowers. These and many others are well worth growing, including the yellow I. Danfordiæ from the Cilician Taurus, and the winter-flowering I. Vartani from Palestine.

ONE OF THE DWARF TULIPS SUCH AS THE YELLOW AND WHITE T. DASYSTEMON SHOULD FIND A PLACE IN THE ROCK GARDEN.

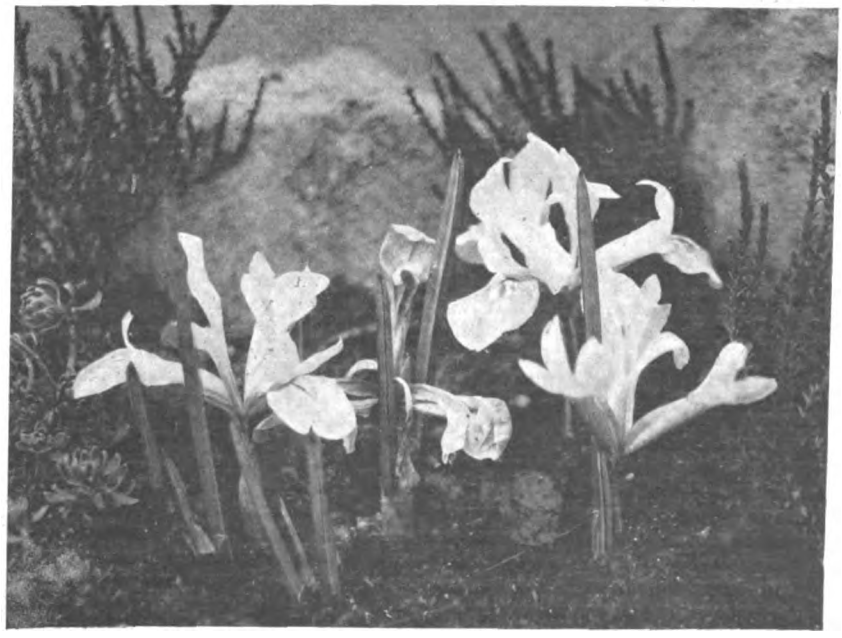
Leucojum vernum, the spring snowflake, is one of the earliest and most beautiful spring flowers, of handsome and elegant drooping habit. The flowers are large, snow white, and tipped with green or yellow. When established in suitable positions large tufts are formed which produce many flowers stems to each clump. Bulbs should be planted as soon as received, as they dislike to be kept long out of the ground. The summer snowflake (L. æstivum), is the tallest and most vigorous member of the family. It produces abundance of foliage and flower stems 2ft. in height, each bearing clusters of three or more flowers.

Many names have been applied to the various muscari species, a charming family of early spring-flowering bulbs, but they all bear close resemblance to each other. In masses nothing can exceed the effect produced by the numerous racemes of bright violet blue flowers of M. conicum (Heavenly blue). M. azureum, also known as Hyacinthus azureus, is a dainty little plant, only a few inches high, with spikes of azure blue flowers, a gem for the rock garden. M. armeniacum is one of the latest to flower, coming into bloom at the end of May. It has long, dense racemes of rich violet blue flowers.

In the daffodil family are several charming little species that are indispensible for the rock garden. N. cyclamineus is one of the earliest of all daffodils, an elegant flower of very distinct form, the trumpet being rich yellow, straight and tube-like, while the segments are reflexed as in a cyclamen. N. triandrus, "Angel's Tears," is of slender growth and produces a cluster of creamy white flowers with a globular cup and reflexed perianth. With larger, snowy white flowers is N. triandrus var. calathinus, a rare plant from Brittany. Others worth growing are the dainty little yellow-flowered N. minimus and N. minor, a little larger than the last, while the two forms of the Hoop Petticoat daffodil should not be forgotten. These are N. Bulbocodium, with rich yellow flowers, and N. B. var. citrinus, with citron yellow flowers. Of Scillas there is the early-flowering S. bifolia from the Taurus mountains, with dainty little racemes of deep blue flowers in early spring. After this comes the Siberian squill (S. sibirica), with larger, bright blue flowers. Some of the dwarfer tulips would be found of great value in sunny positions where the foliage would not interfere with the permanent rock plants. A selection should include the yellow flowering T. Batalinii, the cream coloured T. biflora; T. Clusiana (Lady Tulip), with white petals that are red outside; T. dasystemon, yellow and white, several on a stem; T. persica, brilliant yellow; and T. saxatilis, with delicate rose coloured flowers having a bright yellow centre.

Among the hardy Cyclamen are several beautiful little plants suitable for associating with scillas, daffodils, muscari and other dwarf growing bulbs. The winter-blooming C. Coum is one of the first in flower, producing its deep rose-coloured flowers from December to March. Differing from the above in having marbled leaves is C. ibericum from the Caucasus, with flowers ranging in colour from deep crimson to rosy lilac and almost white. Later on in the spring we have the South European C. repandum, with ivy-like leaves and bright crimson flowers, followed in July by the fragrant C. europaeum, with its large kidney-shaped leaves and crimson flowers. One of the best is the autumn-blooming C. neapolitanum, which produces its flowers before the leaves. The large, handsome, silver marbled foliage is also very attractive and almost worth growing for its beauty alone, but when established the large corms produce a large number of flowers. These vary in colour from rosy pink to pure white and last for a long time in perfection, with the exception of C. repandum, all are quite hardy, and given a sheltered nook that is not too sunny, these charming plants soon become established, and repay a little trouble taken in preparing a suitable site and supplying perfect drainage.

W. IRVING.



ONE OF THE MORE CHOICE MEMBERS OF THE IRIS FAMILY, I. RETICULATA.

DAFFODIL CULTIVATION IN THE OPEN AIR

LIKE every other family, that of the daffodil is made up of members which are not mere replicas of one another, but which vary considerably in their likes and dislikes. King Alfred grows like a weed in the moist climate of Cornwall, but it is a failure in the majority of Midland Counties. The old-fashioned bunch-flowered daffodils, the tazettas, like Gloriosus, Soleil d'Or, Mont Cenis, Grand Monarque, etc., require more warmth and more genial surroundings than can be offered them in most English gardens. The delightful white trumpets, like Cernuus, albicans, Matson Vincent, Mrs. Thompson, etc., are difficult to accommodate and seem only to flourish in certain favoured positions and places. The poeticus varieties like a rather stiff cool soil, and the old "Double White" deep planting in addition. N. triandrus var. calathinus (the large Angel's Tears daffodil) must have exceptionally quick draining soil and a damp climate, otherwise its cultivation is impossible and its life is but a living death. This diversity is only what anyone might expect who has realised the varied habitats of the different members, but notwithstanding all this there is a great residuum which is quite happy and content with the usual conditions of a British garden.

Soil.—After the experience of many years I have come to the conclusion that the ideal soil is one which is well drained and warm, if anything upon the light side, with but little vegetable humus, as deep as possible, and as finely ground up as possible, like the wonderful buttery medium that Mr. Engleheart has at Dinton. A warm soil must not be taken to mean a warm position where the sun's influence is great, for perhaps daffodils do best where there is a certain amount of shade from a hot afternoon's sun, although all the more robust varieties are not in the least particular in this respect; nor must a warm soil be taken to mean a cosy, sheltered position, for although this suits all daffodils, it is something quite different. By a warm soil is meant one which is well drained and which has but little vegetable humus in its composition. Good drainage does not mean a dry, hot soil where there is but little moisture. Moisture is a vital necessity, but it must be available in the place where it will do good, and this can best be expressed by saying that all daffodils like to have their bodies dry and their hands and feet wet. It seems a curious taste to us, but it is what the daffodil likes and, more important still, it suits the daffodil. A damp climate like that of Cornish valleys near the sea, or that of the western and southern parts of Ireland, is exactly what the leaves enjoy, and I am disposed to think that many failures like that of King Alfred in most midland counties, must be put down to the want of a moisture-laden air. Again, although good drainage is vital, there must be a good supply of moisture for the roots. In many places the subsoil is naturally of a damp nature. Where this is not so Nature must be imitated, and very hot and light soils are made much better by burying some strawy manure or partly rotted leaves about 15ins. from the surface to act as a sponge or damp subsoil from whence supplies of moisture may be drawn.

Water-logged soil in beds and borders must be avoided at all costs. In Holland a great deal of labour has to be spent on making and keeping the ground at the right level, otherwise there would be danger of the water being too near the bulbs. So in our English gardens if we have a nasty, sticky soil which holds water like a sponge, we must do all we can to make it lighter by incorporating in it a considerable quantity of *very old* spent manure, and if possible giving it a good double digging every year until it is "humbled." In damp, clammy soils bulbs may be planted within the region of tree roots with the best results. I had a clump of a variety called Astra which obstinately and repeatedly refused to flourish elsewhere in the garden, growing in the rudest health within the sphere of the roots of a Picæa nobilis. I also find a stray clump of Horsfieldii and another of the old Leedsii amabilis "do" amazingly almost literally in the middle of privet hedges. King Alfred needs a warm soil.

Manuring.—Although I can give no scientific explanation of the benefits which accrue from liming, I am none the less convinced of its efficacy. Whenever lime is wanted, it must be at once given in some form or another. Nothing is better than ordinary slaked lime which has been obtained freshly burnt from the kiln, covered, after being made into small heaps, with soil and allowed to crumble. It must then be spread over the land on a dry, calm day and at once dug or forked in. About two tons per acre is a suitable dressing, but for small patches the ground should be covered till it has quite a white appearance, as if there had been a "scattering of snow." Bone meal (fine ground) is the best and safest manure to use, but basic slag may be added in small quantities to heavy and kainit to light soils. In all cases the artificial manure should be thinly spread on the land and then dug in.

Planting.—There is no doubt that all bulbs should be planted as early as possible in the autumn. My tiny seedlings from pans I put in the ground without allowing them to get dry, and all experts who have valuable bulbs simply transfer them from one bed to another, or, if they have been dried off, they get them underground as quickly as they can.

Invariably I would advise early planting. In a certain autumn I planted a bed with Olympia, Fairy Queen and Ben Jonson. Every Monday from July 29th to November 10th I put in a row of each. I was thus enabled to see the effect of early and late planting. The difference between the extreme dates of planting was very great. After October 13th a great falling off in height was noticeable, hence I conclude that mid-October is the latest date for good results. When bulbs are planted in November, or later still, they suffer. The way the bulbs are kept has a decided influence. The longer they are to be out of the ground the more particular ought everyone to be about storage. Never keep the bulbs in bags, but always spread them out on trays or shelves in a dark, dry, airy room or shed, and after October comes in turn them every week.

Depth at Which to Plant.—A bulb should be covered with twice its own depth of soil. This is a safe guide. Thus, one which is 2ins. long may have 4ins. of soil above it, and so on. In light soils the depth may be slightly increased. Deep planting in reason tends to increase the size of the bloom owing doubtless to its having a longer period of growth in which to develop. The flower of a stray bulb left in a bed is almost always extra good. The reason seems to be that if we try to get it up we will find it to be down a great depth.

Position.—Daffodils are not particular about position as a general rule. All the red cups and red-edged varieties with very few exceptions burn very quickly in the sun. The beautiful Sunrise will lose its colour in a couple of hours. So, too, many of the red-eyed poets. The place for all these is under a north wall or hedge, or under a thin clump of trees. In the former positions not only is the colour preserved, but the flowers all have their faces looking, as it were, at you, which is a distinct gain. Triandrus albus, triandrus hybrids, certain white trumpets, probably King Alfred and some other difficult varieties do best planted among the roots of trees in a sheltered place. Excessive moisture in the ground does not suit them, and the roots apparently absorb that which is deleterious.

Changing the Ground.—Like every other plant, the daffodil thoroughly appreciates a change of ground. Where this is impossible the best alternative is double digging, at the same time introducing some old decayed manure in the bottom trench and higher up some boiled bone meal. This is a great asset in producing first-rate show blooms. Where collections are grown in beds by themselves, this should be done every other year. I know its value from my own experience.

Varieties to Plant.—The short list which follows are some of those which will be found most useful for ordinary planting in borders or beds. Red cups do best in pots in a cool greenhouse, where their beauty may be enjoyed before the sun gets too much power. Or, if they can be cut before they are fully expanded and opened in water, or if they can be shaded *in situ*, they are all right planted by themselves. If, however, some red cups or edges are wanted for beds, nothing beats old Barrii conspicuus or Firebrand, Lucifer (in light soil), Blackwell and Torch. More expensive ones are Crœsus, Bernardino and Firetail.

Omitting them all, these gaily coloured gentlemen, I would suggest the following

Digitized by Google

as suitable for ordinary use and ordinary pockets: Trumpets.—Emperor, Cornelia, Olympia, Florence Pearson, Empress, Weardale Perfection and Duke of Bedford. Cups.—Sir Watkin, Pedestal, Seagull, Lady de Bathe, Lady Margaret Boscawen and Noble. Leedsii.—Countess of Southesk, White Lady, The Fawn, St. Olaf, Evangeline and Norah Pearson. Poets.—Virgil, Horace, Sonata and the old, old recurvus. Bunch-flowered.—Aspasia, Jaune à Merveille, Orange Cup and Alsace. If only it were a better doer, Admiration would not be left out. Various.—Campernelle Jonquil, Argent (double white), cyclamineus (rockwork) and J. T. Bennett-Poë.

BULBS AS CUT FLOWERS

BY H. AVRAY TIPPING.

AN ARTICLE WHICH SHOULD ASSIST YOU TO OBTAIN THE MOST ARTISTIC EFFECTS IN THE PLACING AND ARRANGEMENT OF BULBOUS FLOWERS.

LONG ago we abjured the tight-packed, short-stalked bouquets beloved of our grandmothers. Rather do we aim at negligent if artful looseness, at the "airy lightness" that made folks think they saw Grinling Gibbons' flower carvings shake in the wind. We recognise that a bloom is more—much more—than a dab of colour; that it has exquisiteness of form, charm of light and shade, of tone and texture; that it has a thousand delightful ways of poising itself on its stalk, of exhibiting itself in conjunction with leaf and stem.

A WELL-ARRANGED BOWL OF SNOWDROPS.

Nothing in the floral world lends itself better or more readily to such treatment than tulip and daffodil. How noble is the effect of a few of the pink globes of the Darwin tulip Clara Butt, crowning long leaf-set stems and rising high out of a tall beaker. How well we can transfer a microscopic bit of the garden to the sitting-room by wedging into a Japanese bronze "sand bath" a handful of the blooms and buds and leaves of the delicate hued and gracefully shaped narcissus Mrs. Langtry. We can make them look as if they grew there, and cover the bent lead slips we have wedged them with under a sheet of moss fresh from the wood. There is no end to the subjects we may use or the ways in which we may use them. Even short-stalked and leafless tulips yield a good effect of concentrated colour and form limited to the flower itself when a few are put into an open dark-hued bowl as seen on the cover of this issue. Pick a handful of trumpet daffodils and plunge them as they are in a jar that fits them—that holds them up and agrees with them in form and tone—and you get an effortless yet satisfying result, especially when, as in the example illustrated, a ray of sun plays on it and gives gaily of light and shade. Haste and hazard, however, although they may occasionally produce happy results, are not to be adopted as a main principle in flower arrangement. Thought and preparation are surer aids to success. If—as is really best and most satisfying—you rely on the produce of your own garden, you must, as in all garden operations, think well ahead. Consider at once what material you would like to have at hand next spring, and supplement what you may already have by promptly ordering from your bulb grower. Plan out your cut-flower scheme as carefully as you do your bedding scheme. Give consideration to your rooms, to the places therein where certain flowers, duly selected, arranged and placed to suit the picture, will show themselves off and yet agree with their environment, will give completeness without plethora, will add grace rather than produce congestion, will add their own note of form and colour and yet avoid discord. A room crowded with furniture and ornaments, with photographs and "silver tables," with coloured cushions and pinned on bows of ribbon, is no place for flowers. When you do introduce them in the house give them precedence, let them be the chief actors, on them turn the limelight. But if they are to fulfil such premier

TRUMPET DAFFODILS.

Digitized by Google

rôles, they must not only be choice in themselves, not only excel in quality rather than quantity, but they must be trained to their most effective presentment and given the right setting. It is of very great importance what you put them in. For cut-flower arrangement the flower, although the first and essential material, is not the only one. The vessel that gives them water and maintains them in position is part and parcel of the arrangement and must fit its part. It may have beauty, but not obtrusiveness. It is a utilitarian adjunct called forth not to display itself but to assist in displaying the flowers. It is the mount that frames the drawing, the setting that holds the jewel. It must have no separate existence, no assertive individuality. China vases of elaborate shape and rich decoration are detestable for the purpose. Simple bronzes of fine outline and proportioned to their purpose are the very best. They are better than glasses of the same form in that opacity is desirable. The flowers look better when their stems do not show their cut ends, but rise, as it were, from solid earth. Thus, next to bronzes, which are difficult to get, earthenware vessels take the first place. The shapes readily turned upon the potter's wheel are as good as any. They cannot be too simple in form or quiet in colouring, but so long as the basic principle of unobtrusiveness is kept well in sight, a measure of detail and some patterning of colour are allowable. But the great thing is to have enough. When you have selected the flowers from what you have to pick from in the garden you should then select the vessels that will exactly suit from an array of them on a special shelf. There should be bowls and dishes, cylinders and beakers, vases high and low, much open and nearly closed, long-necked and short-waisted. The cleverer and more experienced you are in flower arrangement the less you will want, for the finished craftsman can get his results with the least tools. But, so far as you can, give yourself freedom of selection both of the flowers you pick and of the vessels you put them in.

MAY-FLOWERING TULIPS

TULIPS HAVE LONG BEEN COMMENDED FOR THEIR EASY PROPAGATION, MANAGEMENT AND GENERAL HARDINESS IN ALL SEASONS. WITH THIS WIDE APPEAL, THEIR EXTENDED CULTIVATION AND GREAT POPULARITY ARE FULLY DESERVED IN THE SUBURBAN PLOT OR THE SPACIOUS GARDEN.

THESE easily grown flowers provide a brilliant colour display when the rich greenery of spring is at its best and the pageant of summer has scarcely begun. Tulip-time is one of the gayest periods of the year, and it is doubtful whether the feast of colour from roses, dahlias, sweet peas or carnations can surpass the gorgeous colouring that masses of tulips can produce.

A PLEASANT AND EFFECTIVE ASSOCIATION OF TULIPS AND FORGET-ME-NOTS.

Tulips like a sunny sheltered position, and although the finest flowers are probably produced from plants grown on well-drained soil with plenty of " body " in it, there is no reason to despair if the soil is on the light side. If a liberal quantity of well rotted cow manure is worked into light soils, this binds the particles together and soon forms a good medium. My own soil is a medium loam, rather inclining to the light than to the heavy side. It is mealy and silky to the touch when in proper condition, and with the addition of cow manure, bone meal and lime it seems to suit tulips admirably. Where the soil is heavy and cold, plenty of strawy manure, leaf-mould and remains from the garden fires should be incorporated when digging it over, and the surface soil should be well dressed with lime. The proper application of lime on all soils is recommended for tulip culture. Bone-meal is a safe artificial manure to use, and owing to its slow-working capacity its benefits are spread over a long period. Leaf-mould and finely chopped turves, well mixed into the lower levels, not only prevent the soil from being water-logged, but they are conducive to root formation.

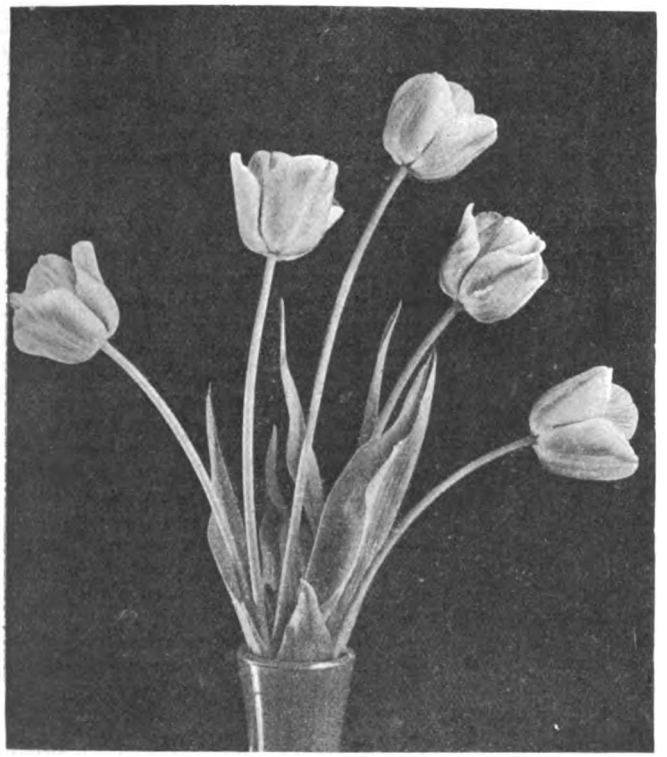
Perhaps I had better describe the situation in my own garden, where I have found tulips grow to the best advantage, as I believe that it is not far off an ideal site. There are two long borders, each about 4ft. wide, on either side of the lawn, and at the back of each there is a privet hedge about 4ft. high and very dense, with various low-growing shrubs near the base of it. One of the borders receives the morning and early afternoon sunshine, the other from about 10 a.m. to 5 p.m., so that the situation is both sunny and sheltered. The borders are large enough to accommodate about two thousand bulbs when closely massed.

Tulips lend themselves to massing. If grown alone, providing they have a suitable background, they are very effective; but, if desired, they may be associated with other subjects, such as wallflowers or arabis; but some care is needed when planning out colour schemes. A carpet work of violas or polyanthas may be used, or the beds or borders may be edged with these flowers or forget-me-nots.

I have mentioned the need for growing them in a sheltered position. Many of the Darwins will attain a height of 36in., and, unless these are protected from the winds by a hedge or wall, some of them will be broken. To tie them to thin stakes, however neatly this is done, would destroy their effectiveness for garden display; but where they are grown in out-of-the-way corners for cutting, protection from wind by any means may be given.

Some people like the appearance of tulips when they are in the half-open stage, *i.e.*, in the early morning or after the sun has gone down; but I think that their brilliance is enhanced when they are seen in full sunlight. Looking along the borders when the sunlight is falling upon the flowers gives one an

Digitized by Google



REV. H. EWBANK, ONE OF THE FINEST OF THE DARWIN TULIPS.

impression of hundreds of illuminated lanterns. Coming closer, there is still another feature to admire in their beautifully coloured bases, and I have spent hours examining the lovely hues and colour gradations, the beauty of which is hidden when the bloom closes.

Generally speaking, we may divide the May-flowering tulips into two main classes, viz., cottage tulips and Darwin tulips. The former, which comprise varieties rescued from the cottage gardens of these islands, and the progeny of the earlier found varieties, are of a somewhat pointed or egg-shaped form, with slender stems. As a rule their height varies from about 18ins. to 27ins. The Darwins are of bolder formation. The flower is cup-shaped with a rather square base, and the petals are rounded. The stalk is long and strong, but there is a certain amount of gracefulness about them and they never look stiff and formal, whether in the garden or arranged in tall vases. They are very beautiful for room decoration. When cutting them do not take more than one leaf with each flower, so that the bulb is not damaged.

When tulips have finished flowering they may be allowed to die down or the bulbs may be lifted and covered with a few inches of soil in a reserve trench, leaving the tops to wither before drying and storing.

I have grown nearly all the best varieties (with the exception of some of the more expensive novelties) in both sections. The following would make a good dozen for the amateur who is starting a collection :

COTTAGE VARIETIES.

ELLEN WILLMOTT.—A beautiful soft creamy yellow with reflexed petals. The flower has a delicate fragrance.

MRS. MOON.—A long pointed bloom of rich golden yellow. Tall and rather late-flowering. A very stately tulip.

GESNERIANA MAJOR.—A brilliantly coloured crimson with a striking blue-black base. One of the most striking varieties for the open border.

ORANGE KING.—This is a very beautiful orange self with a light suffusion of pink on the outer side. It is sweetly scented and very useful for cutting.

INGLESCOMBE PINK.—There are many indescribably beautiful colour blends in this tulip. It changes colour as the bloom ages, from bright pink shaded with buff and salmon to softer and more delicate hues.

LA MERVEILLE.—This is a lovely colour, a blend of salmon and vermilion, and it is pleasing either in daylight or lamplight. It is late flowering. Sweetly scented.

DARWIN TULIPS.

CLARA BUTT.—This variety is well known, but there is nothing quite so rich in the pink shades. The colour is a lovely pale rose pink suffused with salmon.

FARNCOMBE SANDERS.—This shares with Clara Butt the position of honour among the popular Darwins. It is a brilliant colour, which is probably best described as rich cochineal red. It is very strong in habit, large flowered, and lasts a long time in water.

REV. H. EWBANK is a very beautiful heliotrope with a lighter edge, and it is probably the best of this colour at a low price. It is early flowering and not tall growing.

PRIDE OF HAARLEM.—This is one of the largest of the Darwins. The outside is carmine and the inside more inclined to scarlet. It should not be planted near other red shades, or the colour effect will be spoiled.

MARCONI.—I like this variety and Mrs. Potter Palmer, the best of the rich purple shades. The former is a strong grower with large well-formed blooms. Planted near the cottage variety, Orange King, it makes a fine colour contrast, and with me both are in bloom at the same time.

EDMEE is a deep rose with a paler edge. It is a good grower and produces a large, finely shaped bloom on a long stout stem.

All the above-named varieties are inexpensive. There are some very choice kinds in the scarcer sorts, and of these I recommend a selection from the following : Beauty of Bath, a delicate blend of pale rosy lavender and canary yellow ; Boadicea, a rich mahogany brown with an edge of orange ; Scarlet Emperor, a brilliant fiery scarlet ; and Zomerschoon, a glorious fancy, deep salmon rose flaked with yellow. These are cottage tulips. In Darwins, Afterglow, soft apricot orange suffused with pink ; City of Haarlem, a large vermilion self ; Massanet, pale fawn with deeper shading and creamy edges ; Faust, rich glossy purplish black ; The Bishop, rich purple shot with lilac ; and Valentine, an early variety with bright violet flowers displaying an attractive electric blue centre, can be recommended. The latter is one of the largest Darwins in cultivation. I have grown blooms 4ins. long which have lasted three weeks, and which provide excellent decorative effects.

NORMAN LAMBERT.

THE LONG POINTED AND RICH GOLDEN YELLOW BLOOMS OF MRS. MOON, AN EXCELLENT COTTAGE VARIETY.

MUNICIPAL GARDENS of LANCASHIRE

IF there are many claimants for the attractive title of "Garden City," few can hope to rival, much less excel, what Southport has achieved in the making of those public gardens which have earned for that beautiful seaside town so wide a reputation.

When I visited these gardens it was in the flaming days of June, and though drought and the "between season" were a combination which did not tend to present the beds and borders in their brightest aspect, there was evidence on every side of that abounding wealth of colour and interest which are timed to be at their fullest during the show week, and of which the corporation and people of "England's Garden City" are so justly proud.

ONE OF THE FINEST OF HERBACEOUS BORDERS: ROTTEN ROW, SOUTHPORT.

A CORNER OF THE ROSE GARDEN IN HESKETH PARK.

The main attraction for garden lovers at Southport is, perhaps, Hesketh Park, a beautifully wooded and watered area of 30 acres, which is also the headquarters of the Park's Superintendent, Mr. Clarke, and his army of between 60 and 70 gardeners to whom so much of Southport's horticultural fame is due. Space will not permit me to do anything like justice to the cool and ferny retreats, spacious lawns, rose gardens, mixed borders of shrubs and perennials, summer beds, conservatories and other delights of these fine grounds, each of which is so embraced by its own sheltering belt of trees that there is always an element of surprise awaiting you at the ends of the shady walks which link them together.

Early as it was, there was already a brave show of colour here among the delphiniums, irises, geums, liliums, thalictrums, lychnis, inulas, anchusas, erigerons, sweet peas, violas and a host of other things, and some 3,000 rose trees were all promising a rare treat for the August visitor. That bedding roses should succeed at all in the almost pure sand on which Southport is laid out was a surprise, but it was evident that, in addition to the horticultural skill bestowed upon them, these and many other subjects owe no little of their health and well-being to the sinking of the gardens, this giving shelter from wind and bringing the roots nearer the "ream water" which lies in some places only a few feet below the surface.

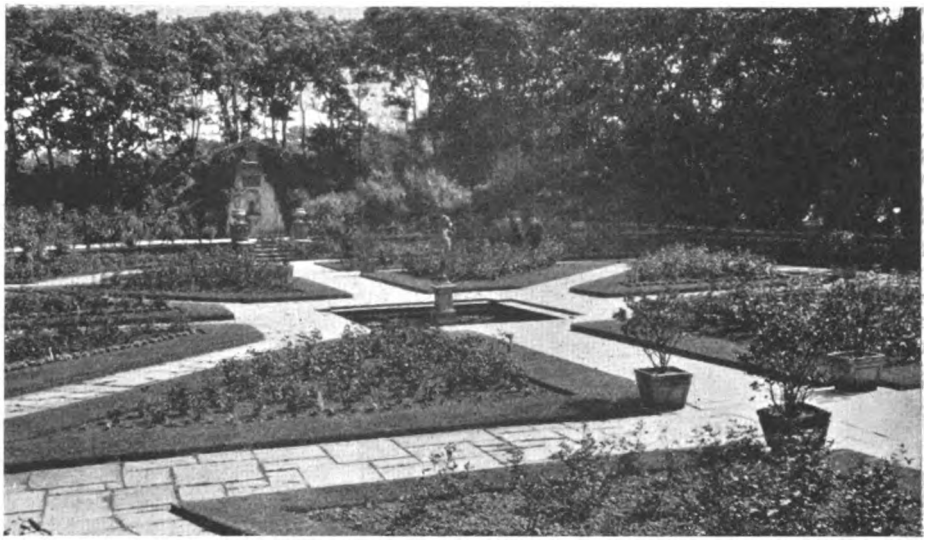
Rock gardening has not yet been made a strong feature at Southport, but there are one or two nice little bits leading the way to further developments in Hesketh Park, and the way in which cistuses and helianthemums, brooms, sedums, many saxifrages, veronicas and aubrietias were flourishing in their sandy retreat was sufficient to encourage further advance in this direction. Near to one of these rock gardens were some twenty specimens of carpet bedding, so admirably executed that they looked like pieces of mosaic or tapestry set in the grass. Whether you regard these as curious relics of a now half-forgotten age of gardening, as highly decorative examples of the "textile" art as applied to horticulture, or what not, they should not be missed by any visitor to the town. Moreover, among the various gaily-coloured occupants of these quaint beds are not a few sedums, echeverias, sempervivums and other plants which are of unusual interest.

These carpet beds, after all, remind one of the fact that here, as in many places, the gardener must be guided mainly by two factors: he must grow what suits his soil and he must, in particular, grow what appeals most strongly to the majority of his visitors. That being so, to experiment and specialise is outside his sphere. The public asks for great splashes of colour, for commanding displays of bright and cheerful flowers, and, in such instances as these, for flowers that will be at their best throughout the later summer and early autumn. Is it surprising, therefore, that one comes across in Southport legions of Paul Crampels and Coltness Gems, vast reaches of antirrhinums and montbretias, of delphiniums, gladioli and begonias? And, when all is said, the public is not a bad judge in these matters, for I question whether there is anything that would do what is expected of them so economically and well and give so much pleasure as, let us say, the occupants of those gorgeous borders in Lord Street, or the wonderful displays which adorn the Marine and Prince's Parks and King's Gardens along by the sea. There are literally hundreds of acres devoted to this style of gardening in Southport alone and it would be difficult to suggest anything that would

Digitized by Google

serve its purpose better. Very cleverly, the purely blatant pageantry of the wholly formal and gorgeous has been tastefully ameliorated by the free use of shrubs, trees and other helpful factors, but the bedding plant still triumphs as it always will under such circumstances.

Though I felt like the Queen of Sheba at the court of King Solomon before getting to the end of the above and other gardens, there was still the great border which flanks Southport's Rotten Row to be seen, and here I soon found that in all the eulogies that one had heard and read of this ambitious display of flowering plants, not a word too much had been expressed. Imagine a gently curved belt of ground, 20ft. to 30ft. wide and fully half a mile long, planted from end to end with the best and choicest of herbaceous and other plants, and you will perhaps gather some idea of the vastness and the splendour of this wonderful border. Here Mr. Clarke has broken clean away from the formal; he has arrayed his thousands of plants in a disarray which is eminently satisfying, but never monotonous, and so cunningly is the grouping carried out, so varied the selection and so well grown the plants, that I found myself being pulled up by something of interest at every yard of this amazing piece of work, which is probably not excelled by anything of the kind in Europe. And when one bears in mind the fact that all these gardens—and I have but touched upon some of them—have been created on what was, comparatively few years ago, a wilderness of wind-driven sand, the signal success which has crowned the efforts of those who undertook the task and still see to its maintenance is beyond description.



THE OLD-TIME SUNKEN ROSE GARDEN IN THE ASHTON GARDENS, ST. ANNE'S.

A PORTION OF THE CARPET GARDENS, HESKETH PARK.

My little tour in Lancashire, whose "Lilies of the Valley" are obviously not all of the factory-chimney genus, as the old cynic had it, embraced the delightful little towns of Lytham and St. Anne's. The former possesses in the Lowther Gardens a pleasant, park-like area overlooking the estuary of the Ribble. Here gardening *per se* is taken less seriously, the several acres being mainly devoted to the uses of a pleasure ground. But there is a breezy and natural wildness about these cliff gardens which is appealing, and in the fine old evergreen oaks, groups of Scots pines, elms and other suitable trees, which break the uniformity of the spacious lawns and give shelter to the flower beds, these Lytham gardens have a charming and priceless asset.

Within a few minutes by road from Lytham one is at St. Anne's. I had often heard of the rock gardens here, but had never realised that in the construction of these the bold spirits who created them had nothing more congenial than a wilderness of wind-raked sand dunes to work upon. They must have been stout hearts, indeed, who undertook to tackle such a hopeless proposition. But it has been done and done well, and when I found myself between banks of Cistus monspeliensis and C. florentinus, great bushes of Senecio laxifolius, all silver and gold, of helianthemums in many varieties, and noted among the limestone boulders the dwarf campanulas and veronicas, dianthuses, saxifrages, sedums, geraniums, thymes and a goodly round of other rock plants, I felt that something like a miracle had been performed. Moreover, there were tucked away in the dug-outs of this sandy waste, over which the wind whistled through the wiry marram, some cheerful evergreens, bright beds of herbaceous plants, groups of Spartium junceum, brooms and other allied shrubs, and, what was still more surprising, gushing falls of water tumbling into placid pools with their irises and other acquatic subjects.

Thence along the front of St. Anne's comes a number of excellent marine gardens, like those of Southport, but on a smaller scale, the formal style again being in evidence with a grateful leavening of shrubby veronicas and other evergreens, tamarisks, sea buckthorn and the like. St. Anne's chief lion in matters horticultural is, however, the Ashton Gardens,

A SUCCESSFUL ROCK GARDEN MADE FROM THE SAND DUNES AT ST. ANNE'S.

Digitized by Google

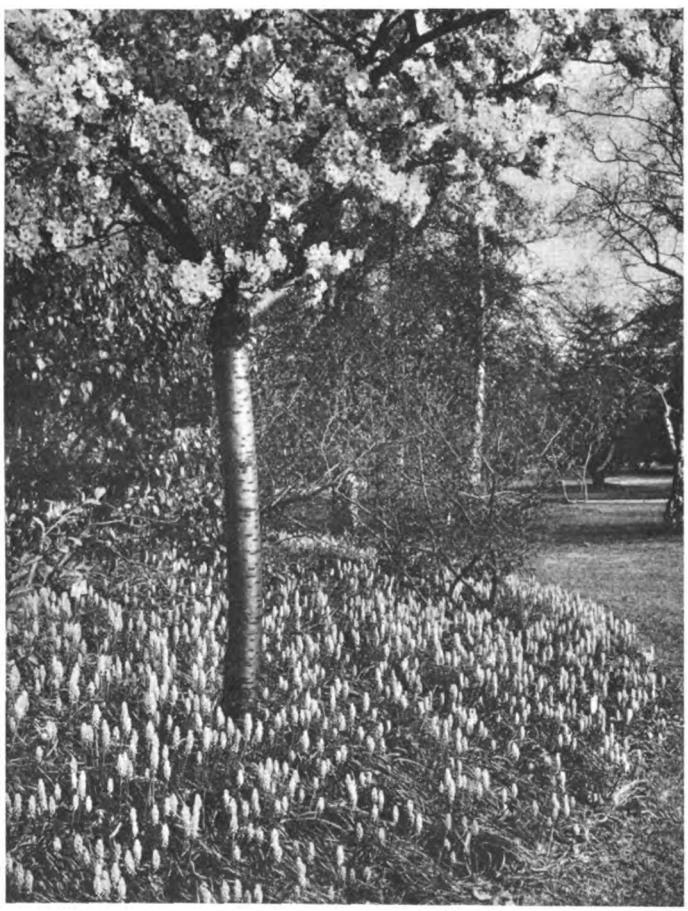
which were presented to the town by Lord Ashton about ten years ago. These should not be omitted from the itinerary of any gardener in this district, for not only have the beautiful grounds all the charm of maturity and seclusion belonging to the private domain, but they contain a wider variety of choice shrubs and trees than is usually seen in municipal gardens, and the lay-out is in every sense attractive. It was the large, old-time sunken rose garden, with its central pool and statue which was evidently the main attraction to the majority of visitors here, but throngs also invaded a circular, tree-fringed lawn which was surrounded and inset with gay borders and beds all done in first-rate order. A picturesque stream, with a fall and many shady retreats intersects the gardens and affords that flavour of wildness which always has a special appeal in a garden set in the midst of a town.

But, if my time—like my present space—was insufficient to allow me to make more than a superficial survey of these sea-coast gardens of the Cotton County, it was enough to afford me two dominant impressions. I was forcibly struck by that keenness and dogged determination to succeed which must have inspired those responsible for these great efforts and which is ever enthusing them to further enterprises. And it was impossible to escape the obvious fact that these municipalities, which have spent so lavishly and so well upon their gardens, have had an immense reward, a reward not merely of the æsthetic kind, but one which has materialised in the shape of that indirect revenue to which the gardens—like the well dressed shop window—are a drawing power and contributory factor of the utmost practical significance.

A. T. J.

THE GRAPE HYACINTHS

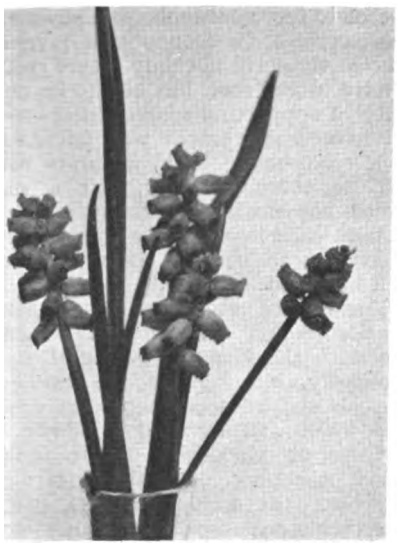
IN selecting this title for my article I am following both Bailey ("Standard Cyclopedia of Horticulture") and Nicholson ("Dictionary of Gardening") in the English name they give to the genus. All the same, I feel it needs a sort of apology, and that a heading like that in Barr's Bulb Catalogue—grape, starch and feathered hyacinths—would, at any rate, have been more explanatory. Muscari would have been above suspicion, for of this family it may truly be said (with apologies to Richard Brinsley Sheridan) "where dictionaries do happen to agree, their unanimity is wonderful." Our Editor has lately introduced us to different types of gardeners. I myself might be called a collection gardener. Not that I ever go into the wilds of the world for my quarry, I gather it in my armchair or (to be more exact in my speech) at my writing desk when I search the appropriate catalogues that either chance or forethought has put in my way. One year it will be for early-flowering yellow tulips under glass; another time it will be for erythroniums; or, again, it will be Michaelmas daisies, or Dutch crocuses. In 1924 it was muscari, and in 1925 Ladhams' lobelias. All the better if I can have two strings to my bow. You cannot, however, do this sort of thing with everything unless you are a Gibbs, Beckett and Aldenham in one. To our Editor's grief he has told us he has found rhododendrons are beyond him and his garden, as they certainly would be beyond most of us. But there are no end of subjects of lesser magnitude which, if I may judge from myself and from the interest I seem able to create among my friends, anyone may go in for and be blessed in his deed. Thus it came about that catalogue time in 1924 saw me searching out all the grape hyacinths I could find. In this way I got together a collection of twenty-one species and varieties, including a Heavenly Blue seedling of my own which, I think, is a swan, but which public taste may class as only a duck. All that I will say about it is that it has a delightful scent and that it is a lovely soft pale blue in colour, totally unlike any other that it was my luck to bring together. I must introduce another aside. Has anyone taken up in a serious way the raising of grape hyacinths from seed, or the crossing the various species? Personal experience tells me that seedlings of Heavenly Blue vary considerably in my garden in their shade of colour, although I am not prepared to say that the old original botryoides, which abounds everywhere like a weed, may not have had something to do with the diversity. So with the trite and hackneyed *verb sap* I pass on and get to grips with the subject of this article—grape hyacinths.



MUSCARI HEAVENLY BLUE IN A CHARMING SETTING.

Let me suppose myself to be asked, "Now you have flowered your collection, what have you to say about grape hyacinths?" What has impressed me more than anything else is the absolutely chaotic state of their nomenclature. There are a few well marked species like paradoxum, comosum and moschatum, which are common property, but after these the deluge. The names in catalogues, the names in Bailey (where I find the largest number of species and varieties listed), and the names in Nicholson are a hopeless mix up. They were altogether beyond me. Therefore I appealed to Cæsar. Cæsar is a very famous gardener who delights in nomenclature and on whose nerves a false name is as a false note to a musician. Cæsar's verdict has made "confusion worse confounded." He found them distinctly "puzzling," and in no wise, I am sorry to say, mended matters. Here, then, is a chance for any botanically inclined gardener to set himself a stiff job, whose accomplishment would be a sort of Davy's safety lamp amid the pitfalls of unsupported naming and general haziness. From what has just been said it will not surprise readers to be told that there is a very striking family likeness between many of the species or varieties (for who is going to give an *ex cathedra* judgment as to which is which?). It rather surprised me. Not that there are no break-aways from the small blue urn-shaped bells which are *de rigeur* with the majority. There are the lunatics, comosum and comosum monstrosum, with part or the whole of their inflorescences turned into vegetable hairs; and there are the

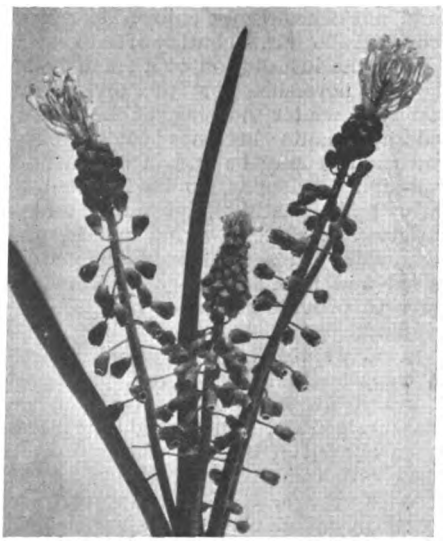
Digitized by Google



THE BLUNT-LOOKING M. MOSCHATUM.

moschatums or chameleons which change their colour with age. There is also an exception which proves the rule in the leafage of latifolius, which in its earlier stages of growth might verily be expected to turn into something after the style of our well known Lords and Ladies.

From a garden point of view, it may be said "there is more in their bark than in their bite." Their nomenclature is rather frightening, but, as far as my experience goes, they are easily accommodated in the matter of soil and situation. Any good garden soil suits them, and any situation so long as it is open. The flowers of the moschatum (musk) are affected by sharp frosts, so it is well to put them in warm and sheltered positions. Some species and varieties make good subjects for growing under glass, especially the feathered hyacinth (comosum monstrosum), as then its colouring is so much more delicate and the inflorescence develops more fully and has not the rather starved, unexpanded look that it frequently has when grown out of doors, but hard forcing must be avoided. I fear a large permanent bed (say, 4ft. wide by 10ft. or 12ft. long) in full sun, with nothing in it but a thickly planted mass of Heavenly Blue, is out of the question in many gardens; but if such should be possible, whenever the sun is a reality, there will ascend therefrom such a spicy smell that the unknown author of the famous poem about "what little girls are made of," had he been guided by his sense of smell alone, would surely have put it down as one of the ingredients "sugar and spice and all things nice." A far easier way to enjoy it is to gather a handful and put it in a vase in a warm room. Moschatum similarly treated would be



THE SHOCK-HEADED M. COMOSUM.

over-powering. Three or four spikes are sufficient for most noses. A little gathering of this size is reminiscent of a refined poetaz scent. Two of the three pictures in this number and the two illustrations which will appear with the next article show the diversity in form which is to be found in the species comprising the genus. JOSEPH JACOB.

SMALL GREENHOUSES AND THEIR UTILITY

THERE IS NO MORE IMPORTANT ADJUNCT TO THE GARDEN THAN THE SMALL GREENHOUSE, BUT ITS PROPER MANAGEMENT IS NECESSARY. A FEW TIMELY HINTS ARE GIVEN BELOW.

FOR some few years prior to the changed circumstances brought about by the war small portable greenhouses were constructed in quantities which were calculated to exceed all possible demands and, as in many other lines of business, efforts were made to meet prodigious competition by cutting down prices until some manufacturers used materials of such flimsy character that the occupants of the structures were afforded scant protection from severe weather, while some of the smallest houses could accommodatescarcely as much as a three-light garden frame. Small wonder that owners experienced irritation, failure and disappointment from such mere parodies of greenhouses, and that in consequence a widespread impression was created that the small greenhouse is but a snare and a delusion.

A COMPACT AND UP-TO-DATE GREENHOUSE SUITABLE FOR A SMALL GARDEN.

That is a true conception in so far as it relates to the 7ft. by 6ft. house, with sides of half-inch match-boarding and rafters that could scarcely sustain the weight of the thinnest, cheapest foreign glass, but it would be a grievous mistake to allow the opinion to obtain that a well constructed greenhouse of small size is useless, for, as a matter of fact, a house of 10ft. by 8ft. is capable of adding greatly to the enjoyment of one's garden, and, so far from the cost of a strong structure of this or slightly larger size being in the nature of an extravagance, it is quite capable of proving a sound investment and aid to economy. Much may be produced by the aid of a cosy little greenhouse, at a minimum of cost, which

Digitized by Google

could not otherwise be enjoyed except at a considerable annual outlay of hard cash.

With the installation of a small boiler of the horseshoe or the cylindrical patterns, winter housing of half-hardy bedding plants becomes easy; chrysanthemums may be had in bloom until well-nigh Christmas, to be followed by early bulbs, astilbes, primulas and a variety of other flowering plants, and, meanwhile, on shelves, seedlings may be raised and plants propagated from cuttings to provide stock for next season's bedding.

In early spring begonias may be started in trays and later on potted to provide a grand display of bloom throughout the summer, or, if preferred, the house, when cleared of bedding plants, may be filled with tomatoes or with melons.

With the aid of a supplementary frame in which plants may be hardened off or azaleas, liliums and spiræas may be started, and in which primulas, cyclamen and calceolarias may spend the summer, a small greenhouse may be kept gay all the whole year round, and even under the stages a good crop of forced rhubarb or seakale may be produced to supply a moderate-sized household.

Without heat a small greenhouse will provide accommodation in spring for a most interesting collection of choice alpine plants in pots and pans, which can be removed to a plunge bed outside when flowering is over, thus making room for the summer batch of begonias or the alternative crop of tomatoes. The lover of hardy ferns needs but to select a position with a northern exposure and the small greenhouse affords ample accommodation for a fine collection which can be attended to in comfort whether wet or fine.

The choicest of the smaller rhododendrons and many remarkable shrubs, which find our erratic climate too trying, will make handsome plants of never waning interest when afforded the shelter of a glass roof.

Rosarians may enjoy early blooms from plants in pots, and from a good climbing rose trained to wires across one end of a span-roof or on the back wall of a lean-to house.

For hybridising, for the saving of seed of one's highly prized specialities, and for preparing plants and flowers of many kinds for exhibition, or even for decoration of rooms, verandas and balconies, the small greenhouse is a real boon, and, of course, the lover of perpetual-flowering carnations requires a greenhouse to enable him to grow his own blooms. The particular design and the interior arrangement of staging, etc., and also the situation of the greenhouse, must be governed by the individual requirements of the owner, but whatever these may be it is invariably essential that the house shall be strongly built of well seasoned materials and that ample provision shall be made for free ventilation without draughts. Safety lies in dealing with a high-class firm who specialises in quality of materials and workmanship. Messrs. W. Duncan Tucker and Sons, Limited, Boulton and Paul, Limited, Foster and Pearson, Limited, W. Messenger and Sons, Limited, and Skinner Board and Co., Limited, are a few of the well known firms whose addresses may be found in our advertisement columns, and who will furnish illustrated catalogues and specifications of really serviceable houses to suit all purposes.

Tenant's fixtures made on the sectional building principle with wooden walls are quite satisfactory so long as the timber is substantial and the joinery good.

Freeholders will, of course, be well advised to have houses built on brick walls, because the additional first cost makes for longer life and economy in upkeep, and in the roof structure the cost of a few additional iron stays and brackets will be money well invested, because they will not only ensure greater rigidity in the roof, but add to its capability of supporting suspended shelves.

Where a convenient wall offers itself as a ready-made back, a lean-to house will be found cheaper, but a span-roofed house with upright glazed lights on both sides is preferable for such plants as require to be kept symmetrical and well balanced.

There is an advantage also in having ventilators on all sides of a house, not with the idea of opening all simultaneously, but because the ventilation can always be secured on the leeward side when a strong wind is blowing.

Cane or wood-lath blinds fastened under a coping along the ridge of the roof are the best means of shading, for they need only be drawn when the sun is powerful, giving the occupants of the house full benefit of unrestricted daylight at all other times.

Portable stages are an advantage where a house may be required for tall chrysanthemums in autumn, and a miscellaneous collection of small young plants in spring.

If the house is to be heated at all, see to it that both boiler and pipes are of sufficient strength and capacity to maintain a good temperature without hard driving; it is better to be content with an unheated house than to have the constant anxiety of grappling with incompetent heating apparatus. Be sure to fix a good-sized water tank inside the house and run a pipe to it from the gutter troughs which receive the rainwater from the roof. Do not, however, overlook the necessity for an overflow pipe to carry excess water clear away or the greenhouse floor may be flooded, with unhappy consequences.

In the illustration a serviceable amateurs' greenhouse is depicted which will serve many purposes. A. J. M.

CORRESPONDENCE

FORTUNE'S YELLOW ROSE.

SIR,—I have just seen your correspondent's letter of July 4th asking the name of the climbing rose so much grown on Lake Como. I think he will find it is listed in English catalogues (Messrs. Easlea and Messrs. Cant both have it) under the name of Fortune's Yellow. It is, however, classed as "tender" and "must be grown on a south wall." I believe at one time it was called Beauty of Glazenwood.—A. L. HOWARD, *Gloucestershire.*

THE MINIATURE DAFFODILS.

SIR,—Following up the correspondence on this subject, I wonder if your correspondents have noticed the remarkably sweet scent of that little yellow gem, Narcissus juncifolius. It is almost the sweetest scented, I think, of all the daffodils. A very beautiful little hybrid between this and triandrus albus was exhibited at the Birmingham Daffodil Show this year by the raiser, Mr. J. S. Arkwright, and although as yet I believe unnamed, was recommended for an award of merit by the Floral Committee of the Midland Daffodil Society. The flowers were, as nearly as one can imagine, intermediate between the two parents. Mr. E. A. Bowles and I had a sniff at it, and the sweet juncifolius perfume was plainly apparent. Some years ago I crossed Narcissus triandrus calathinus with minimus, and obtained a flower with white cup and pale yellow perianth, an unusual circumstance, which seems to throw some light on the origin of the now seldom seen triandrus pulchellus, a flower of similar unusual relative colouring. Cyclamineus with minimus is another cross that I (and I believe others) have made; but I agree with Mr. Engleheart that all these little plants prove difficult to keep. It is a pity, for they have a most fascinating charm of their own.—F. HERBERT CHAPMAN.

SIR,—I have been interested in the correspondence by Mr. W. A. Watts in THE GARDEN of April 4th *re* miniature daffodils, and especially in the illustrations that accompanied it. I have had for a number of years a variety that I obtained under the name Infanta. As far as shape and appearance go, the flowers of this Infanta exactly resemble that figured as cyclamineus hybrid. On referring to the Classified List of Daffodil names as issued by the R.H.S. in 1923, I find that Infanta is described as a triandrus hybrid, see page 32-35, Infanta (Batson). Not only do the flowers of Infanta as I grow it resemble a cyclamineus hybrid, but its period of flowering is *very early*—before that of practically all the trumpets, while that of most of the triandrus hybrids is mid-season or later. I am sure that Infanta as I grow it is not a triandrus hybrid, but a hybrid from cyclamineus. So far, it has flourished exceedingly well with me, and is very floriferous. I would be glad if any readers of THE GARDEN could supply me with any information as to the origin of Infanta.—GEO. T. MAUNDER, *Gisborne, New Zealand.*

FEIJOA SELLOWIANA.

SIR,—I was pleased to see Mr. H. G. Hawker drawing the attention of readers of THE GARDEN (August 15th), to that delightful evergreen flowering shrub, Feijoa Sellowiana. My experience regarding full sun for this plant coincides exactly with his. I have planted it in semi-shade and also in full sunshine; those planted in partial shade have only displayed a solitary flower here and there, while those planted in a south aspect, exposed to the full glare of the

PLANT NOW for September Flowering

BLUE CROCUS AND WHITE COLCHICUMS.

CROCUS SPECIOSUS. The most beautiful of all the autumn-flowering Crocuses, with large, brightly feathered, violet blue flowers, vigorous, floriferous and exquisitely fragrant. Of untold value either for garden effect or for growing in bowls. .. .. Selected corms, **2/6** doz.; **18/-** 100

Crocus speciosus Aitchisonii. A scarce form, larger and more richly coloured than the type. Flowers later. .. .. **5/-** doz.; **35/-** 100

Crocus zonatus. Very lovely lavender flowers with yellow eyes. .. .. .. **1/9** doz.; **12/6** 100

COLCHICUM AUTUMNALE ALBUM. Large Crocus-like blossoms of the purest white. Among the most beautiful of Autumn flowers, and equally at home in lawn or rock garden. Increases fast. .. .. **2/6** doz.; **18/-** 100

COLCHICUM SPECIOSUM ALBUM. F.C.C., R.H.S. The finest of all. A very rare and choice plant, yielding most lovely pure white globular crocus-like flowers with prominent golden stamens. Flowers throughout September and October .. .. **1/6** each; **16/-** doz.

Colchicum autumnale. Our native Meadow Saffron. Massive rosy purple goblets. **2/6** doz.; **18/-** 100

Colchicum Bornmulleri. Cup-shaped rosy lilac flowers. One of the finest species. Early flowering. **4/6** doz.

FREESIAS
should be potted now for early flowering

Refracta Alba Major. Exceedingly fragrant. Grows about a foot high with six to ten pure white flowers on a stem. Splendid for forcing. .. .. **1/3** doz.; **8/-** 100

Leichtlini Major. Lovely primrose yellow. Very fine. .. .. **2/-** doz.; **14/-** 100

If you are contemplating the erection of a Glass House we should be glad to send you interesting and helpful literature to aid you in your choice of a suitable structure.

First—from the first

WHEN the designing and building of Glass Houses became an industry—when purchasers realised that a Glass House was something more than a combination of glass, woodwork and bricks—Duncan Tucker and Sons, Ltd., were the first to apply their practical building experience to the problem of efficient Glass House construction.

This was many years ago—since then Duncan Tucker and Sons, Ltd., have steadily progressed, and their structures are to be seen in every part of the country. In spite of increased competition, they still hold the proud position of being the largest builders of Glass Houses in Great Britain. Whether you are contemplating the renovation of an existing Glass House, or the erection of a new one, this experience is yours for the asking.

sun, have always blossomed freely, though none have fruited. In fact, I think they rarely bear fruit when grown in the open air in this country. It forms a very fine bush in the open in the south-west counties. Its foliage is attractive, while the flowers are very quaint, thick, waxy white, with a conspicuous tuft of crimson stamens. Mandevillea suaveolens growing here in the open air on a south wall has been yielding a mass of its white fragrant flowers for some considerable time.—F. W. RICH, *Elfordleigh, Plympton.*

TRENCHING OF SOILS.

SIR,—I have been very interested in the various views on trenching that have from time to time appeared in your valuable paper THE GARDEN. "J. H." may be wrong when he is so surprised that so little interest seems to be taken in the correspondence on the subject; on the contrary, probably everyone reads it with interest, but from various reasons do not care to express an opinion in writing. To my mind trenching is all important, but I should have been doing a very foolish thing to have brought the bottom to the top, as the soil I had to deal with for nine years was Sussex clay the colour of American cheese 13ins. from the surface, and in some parts of the garden was what we called shray. Both for the growing of plants and working of the soil it would have been bad practice. I trench as early in autumn as possible, the dryer the soil the better, thoroughly break up the bottom of the trench and leave it there, forking into the bottom as much manure, leaf-mould or rotted vegetable matter as can be spared, leaving a layer on top as well. The one thing I had in view was to ensure good drainage by breaking up the bottom, and if one is fortunate enough to have dry weather during the whole operation the better it will be. A good illustration of the effects of mixing the clay with the top spit was a drain that had been put in several years before I took charge across the garden. It was quite easy to mark the drain by the less robust growth of any crop that was put on in spite of several efforts to give that area more manure, etc. I never sowed seed on it, as I found that if dry weather followed sowing it was far from satisfactory. The method I followed produced vegetables in plenty. Since leaving Sussex I have had experience of a number of different kinds of Suffolk soil, and in the particular garden I had charge of at Bury St. Edmunds the bottom spit was almost gravel and quite useless as a top soil. The soil I have now is probably the best that I know, not nearly so stiff clay as Sussex, and I see no reason for altering my method of trenching. I am a firm believer in breaking up the ground deeply, and would never plant new fruit quarters or even herbaceous borders without first trenching the ground as early as possible in autumn. I have never been fortunate enough to have soil good enough at the bottom to change places with the top.—W. PARKER.

PROPAGATION OF IRIS.

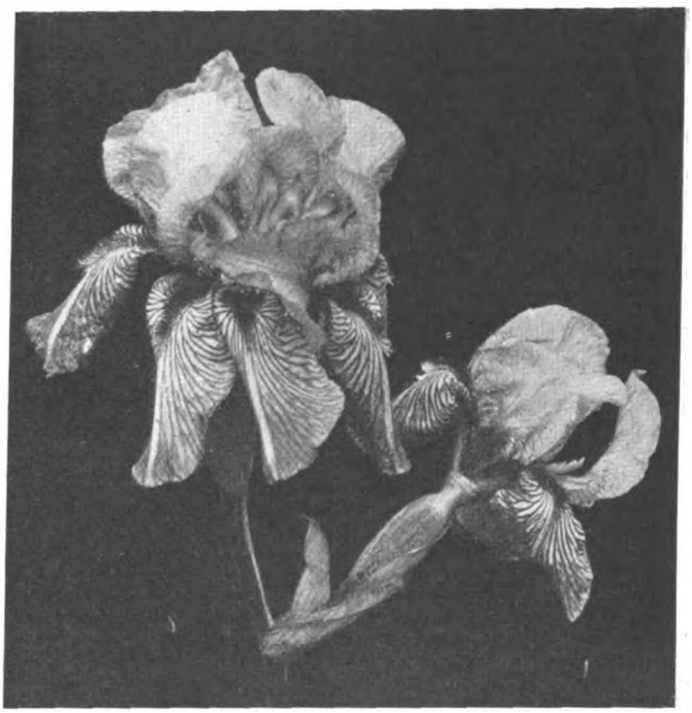
SIR,—The following note may be of interest. I ordered two dozen plants of the German iris last October from a first-rate firm; the plants, on arrival, were big and strong, but smothered with "spot" disease. I had no knowledge of the culture of these plants at all and I decided, entirely on my own, to take severe measures with the disease; they were to be cured or die, so I razed off all growth from the rhizomes, leaving them quite bald, thinking that I had probably "done" for the lot. I then planted them in their permanent places.

Next spring each of the rhizomes appeared as pale green in colour. On examining very closely the rhizome was a mass of minute growth all over, and from each plant I got from ten to twelve young, strong plants, which flowered the next summer. Out of the two dozen plants, I only lost one, the smallest increase on any one plant would be eight. I have since wondered if the trade increase irises in the same way.—H. C.

AN ABNORMAL FLAG IRIS.

SIR,—I wonder if any of your many readers who grow the bearded flag iris can tell me if it is at all unusual to find a flower bearing more than the usual three standards and falls. I enclose a photograph of one I cut a few weeks ago from my garden, which is unusually large and has no fewer than seven standards and seven falls. The variety is, I believe, Mrs. Reuthe, but I am not quite certain.

I have grown the flag iris for a number of years, but this is the first time I have seen anything so remarkable in the way of abnormal development. The clump from which the spike was cut is flowering profusely, but none of the other blooms is other than normal.—B. HANLEY.



A BEARDED FLAG IRIS WITH SEVEN STANDARDS.

CURES FOR ONION DISEASES.

SIR,—I was very interested to read, in your issue of THE GARDEN for August 8th, of the various remedies recommended to prevent disease and insect pests taking their toll of vegetables, thereby robbing the cultivator of the fruits of his labour. With regard to onions, however, I find myself at variance with your writer, after six years of experimental work on onions grown in these gardens. To begin with, the soil here varies from light, gravelly to clayey loam, which precludes, to a certain extent, any difference occurring through the different classes of soil. Again, allow me to impress upon all readers how essential good cultivation is in warding off disease, by encouraging that free, "kind" growth throughout the life of a plant, so gratifying to a keen gardener. Another point which is often overlooked is the supply of available plant food at all stages of growth. In the case of onions, it is very unwise to rely solely on farmyard manure to give a bounteous crop, as it seldom contains sufficient potash, and there is always the risk of the plants receiving a check, which would render them susceptible to disease. The risk is greater on light than on heavy land. A good and cheap potassic manure is wood ash, when available. This should be dug in in the autumn along with farmyard manure, where autumn digging is practised, but, of course, trenching would be better in most cases. If this treatment be followed up by two applications of nitrate of soda or sulphate of ammonia during the early stages of growth, one can reasonably expect the plants to have a sufficient supply of available plant food during their lifetime. Perhaps all this may appear in no way connected with disease and pests, but a little thought will prove otherwise. If plants are in a healthy condition, the risk of disease is minimised. I have found the greatest aid in warding off an attack of onion fly and maggot is by the use of Terrafumite. One is inclined to think the various 'ites sold by nurserymen, etc., are identical, but I have always found Terrafumite the best. My method of applying is as follows: For spring sown onions, on land previously manured with farmyard manure and wood ash, 1 cwt. of Terrafumite mixed with 28lb. of super-phosphates, 30 per cent. spread at the rate of 1lb. of mixture to three square yards the day previous to sowing seed, if possible, but if there is any doubt about the weather, apply in the morning, rake well in, tread or roll the ground and sow seed in the afternoon. In order to test the merits of Terrafumite, 1,000 onions were planted out as a plot, using 1lb. of Terrafumite to three square yards, but no super, as I considered the land was good. The onions were planted out April 14th, and fed twice with sulphate of ammonia, about a teaspoonful the middle of May and the same quantity about four or five weeks after. Two seasons previous the ground had been planted up with onions, but the crop was a failure owing to maggot. Out of the 1,000 onions planted only six were affected with maggot sufficient to spoil the bulbs for kitchen use and three or four more were slightly affected. The varieties of onions were Dickson and Robinsons' Premier, Sutton's A1, and Clibran's Exhibition. The yield was just over 2,000lb. Another 1,000 onions were planted on a piece of ground at the same time, but no Terrafumite was used. During May, June and July they were sprayed five times with paraffin emulsion, but despite all this the crop was a failure owing to maggot. By the first week in August whole rows of plants were riddled with maggots, and the few survivors succumbed to mildew within the month. This year I had 500 onions planted to form a plot, treated the ground with Terrafumite, and at the time of writing I have five blanks owing to maggots. In the evening scores of flies could be seen on the tips of the plants and plenty of eggs could be found, so to make sure I sent a boy through the plot to sprinkle Terrafumite between the rows and hoe it in. I think I can attribute my success to Terrafumite.—F. C. KING, *Levens Hall.*

NOTES OF THE WEEK

REMOVING WALLFLOWERS TO FINAL QUARTERS.

IT is a matter for surprise, that, after pricking out wallflowers and growing them on during summer, more care is not exercised in getting them into their final quarters in autumn. One sometimes hears the complaint, "we lost so many of our wallflowers last winter," that would almost lead one to imagine they were not hardy, did we not know that the blame lay at the door of the grower, because of careless shifting. In many instances we know, soil is loosely forked, and plants drawn out to be planted elsewhere instead of each plant being treated individually, and taken up with a ball of soil. Such removal takes up time, and is more trouble, but it brings its own reward in the spring. To disturb the roots as little as possible in October should be the aim of the grower, as, if this is carried out, little or no loss ensues, be the winter what it may. I write from many years experience of these, the sweetest of spring flowering plants.—W. LINDERS LEA.

SOME FORMS OF RHODODENDRON DECORUM.

WHEN discussing R. decorum Mr. E. H. Wilson describes it as one of, if not the most widely distributed of Chinese rhododendrons. It is not surprising, therefore, to find that there are many and varied forms, or varieties, of this species continually appearing among the rhododendrons raised from seeds obtained by several collectors, from Père Delavay down to the present day.

Not only do the plants vary in habit, foliage and flower, but there is considerable variation in the degree of hardiness, due, no doubt, to the different districts and altitudes from which the seeds were obtained. One very noticeable trouble is the large number of flower buds of R. decorum destroyed or ruined by frost during the winter. This is not very apparent at first, but when the buds should commence to push in spring they turn brown and fall off at the slightest touch.

Among these numerous forms of R. decorum we thus have a prolific field for the selection of not only the best in habit and floral features, but also the bushes best able to withstand the varied changes of our British climate in winter.

Some of the most distinct forms have been given varietal and even specific names. Among these is R. serotinum, which was given an award of merit when exhibited by the Director of Kew at the meeting of the Royal Horticultural Society on August 11th. The flower trusses were cut from one of the original plants raised from seeds collected by Père Delavay on Mount Tsong-chan, Yunnan, at 6,700ft. elevation in 1887. This very well known French missionary sent the seeds to the Jardin des Plantes, Paris, from where several seedlings were obtained for Kew in 1889. It is worth noting here that Père Delavay at the same time was the first collector to send home seeds of two of the most distinct and useful flowering shrubs among the Chinese rhododendrons, R. racemosum and R. yunnanense.

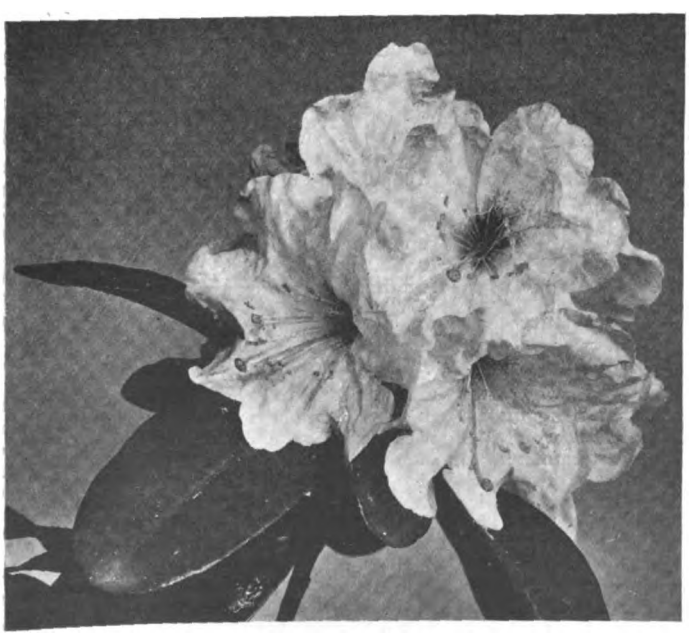
R. serotinum is a loosely branched shrub, 15ft. to 18ft. in height, no doubt more with age. The leaves are oblong lanceolate, up to about 6ins. long and 2¾ins. wide, glabrous, dull green above, glaucous beneath. The flowers are white, daintily crimped, with a conspicuous red-brown stain in the throat, a seven-lobed, flattish bloom, the largest 4ins. across, borne six to eight in a loose truss, and pleasantly fragrant. The name "serotinum" meaning autumnal, is very appropriate, for the season of flowering extends from July to September or October.

R. auriculatum.—This is one of the most distinct and interesting of the many Chinese rhododendrons added to our gardens during the last twenty-five years. The truss which was exhibited at the Royal Horticultural Society's Show on August 11th was from one of the original seedlings, now a robust bush 13ft. or 14ft. high, and as much in diameter, bearing this year upwards of fifty trusses of flowers. In a wild state Mr. Wilson found small trees or huge bushes up to 30ft. in height. The oblong leathery leaves are notably large, on vigorous seedlings 1ft. or even more being not unusual, and 4ins. to 5ins. wide, conspicuously hairy on the leaf-blade, with bristly stalks. The white flowers are funnel-shaped, 3½ins. to 4ins. across, five to eight borne in a loose truss, the corolla seven-lobed, the flower stalks glandular hairy.

R. auriculatum is very distinct in several particulars. There is no sign of the new season's growth beginning until July is well advanced. The majority of the flowers are borne on the lower and least exposed growths during August, not as is usual with most plants on the most vigorous shoots in the best placed positions.

The plant of R. auriculatum which is the subject of this note, has deliciously fragrant blossoms, but this pleasing feature is not apparently common to all the plants of this species.

Flowering late in the season, both rhododendrons should be planted in positions sheltered from the mid-day sun, with liberal mulching material to keep the surface soil cool and moist.—A. O.



R. SEROTINUM, A CHOICE LATE-FLOWERING SPECIES.

LILIUM GIGANTEUM IN SEMI SHADE.

THE accompanying photograph illustrates the noble effect secured by the massed planting of Lilium giganteum in a sheltered corner of the wild garden. It has proved itself to be quite hardy, and at the beginning of July it produces its racemes of from six to twelve funnel-shaped white flowers, tinged with green on the outside and with purple in the throat. When fully expanded they measure 1in. round the base and from 5ins. to 6ins. at the tip, the length also being from 5ins. to 6ins. The broad leaves often attain a length of from 1ft. to 1½ft. on a petiole 1ft. or more long. They are from 5ins. to 6ins. apart at the base of the stem, gradually diminishing in length and getting closer together until those beneath the raceme are not more than 3ins. or 4ins. long. The stem, which attains a height of from 6ft. to 10ft., is erect, measuring 2ins. or 2½ins. in diameter at the base. The requirements of this giant member of the lily family are not so exacting as one would imagine. Providing protection from high winds is supplied, any light, well drained soil of a good depth will be found suitable. The bulbs should be planted at the end of July, or immediately after flowering should a new bed be required, with their crowns just below the surface of the soil, say, from 6ins. to 8ins. deep. Little other attention will be found necessary beyond a mulching of rotten manure and a liberal supply of water given as soon as the buds appear.—A READER.

L. GIGANTEUM LOOKS WELL IN THE MASS.

HONESTY.

THE season has been very good, in spite of the drought, for this old-fashioned flower, with its quaint name.

After blooming profusely for weeks, the seed has ripened dry and clean. It seems a pity that this plant is not more generally known and cultivated, if only on account of the beautiful centre piece of its seed vessel. This, when the two outer portions and seeds are removed, appears with the sheen of white satin, of gossamer texture and fairy lightness, and lasts a long time.

Mixed with berries, flowers or foliage, or alone in coloured or iridescent glass vases, it is very effective, and, as it grows in clusters on short branches from the main stem, can be used with advantage in the decoration at

Digitized by Google

weddings or harvest festivals. The flowers are also very pretty, and large masses of the plant in bloom, both plain and variegated, growing on a bank, is a charming sight in the spring sunshine. It grows to a height of about three feet and flowers the second year. The seed should be gathered unsoiled, if possible, but in a wet season this is a difficult matter.

A bowl of honeysuckle, flowers and berries, sprays of the small red garden fuchsia and silvery honesty, is a combination of sweetness and beauty.—(Mrs.) A. S. COOPER.

FREESIAS BY VARIETY.

FREESIAS are ever favourites, but many growers only procure them in a mixed selection and miss the charm of having them in choice named varieties. Refracta alba is the popular white, but Purity is distinctly better, the blossom being larger, fuller and more lasting. Excelsior is a charming cream, shaded apricot; the flowers of this vigorous variety are larger and better than any of the other kinds we know. Chapmanii is a glorious orange yellow, the flowers being again large and of good substance. Passing to the shades of blue one cannot forget to mention Heavenly Blue, a soft, sky blue with blotch of deep golden yellow. Of lavenders and mauves there are Amethyst, a very pale tint, and Sweet Lavender; both should be introduced because of their colouring which is very attractive. The reds, so difficult to describe, but so dainty and pretty, would include Rosa Bonheur, a bright, robust variety with large rose flowers; La Charmante, a delightful rose, shaded apricot; Robinetta, a bright red; and Salmonetta, a salmon pink. Sunset, a new variety, is distinct, the flowers being almost brown. Of course, there are other kinds, but we speak only of those we grow. Amateurs need not be overwhelmed with their number; even six bulbs in a pot will give a wonderful crop of blossom and since each spike bears many flowers, the whole will become a crown of exquisite colouring.—CLYDESDALE.

ASTER THOMSONI.

EVEN with the presence of an almost bewildering array of asters, or Michaelmas daisies, which have been produced by raisers of new varieties, many of the original species yet find high favour among growers of hardy flowers. Most of them are easy to cultivate, but a few baffle some growers, if not to grow, at least to increase readily. Of the latter category is Aster Thomsoni, which is a native of the high lands of Kashmir and Nepal. It is a very beautiful species, which is not over difficult to cultivate in light soil, and I was greatly delighted to observe a very fine specimen growing in the charming garden of Captain Stewart, Shambellie, Newabbey, the other day. There are two forms, and it was the dwarfer and better of the two—A. T. nana—which was at Shambellie. The late Mr. Farrer did not err on the side of extravagant praise when he said that A. Thomsoni was "one of the most beautiful of all." The typical species is said to be about 3ft. high, but this form is very rarely met with in British gardens, that usually seen being A. Thomsoni nana, which is generally little more than 18ins. or 24ins. in height. It is exceedingly charming, and gives an abundance of its lilac blue flowers, which begin in summer and are produced for some time singly on stems clad with grey-green leaves toothed, rather oval in form and pointed. The question of propagation is one which has exercised many. Farrer says that it is "deplorably difficult of increase, as it neither runs nor seeds nor forms a clump." On the other hand, Nicholson's "Dictionary of Gardening" informs us that it is "increased by seeds or cuttings; it should not be divided." The latter quotation would infer that it does produce seeds, but I have not seen them, although they are offered for sale. But the plant can be divided when it forms a clump, as it certainly does, though Mr. Farrer said it did not. I have had a clump myself, and the fine plant at Shambellie can by no means be called anything but a "clump," and a good one at that. I believe that spring, when it is making growth, is the best time for division. A sunny position in well drained, rather light soil should be given to this most attractive Starwort. Under the name of A. Frikarti new asters said to be chance seedlings of A. Thomsoni are among the novelties of this autumn's lists.—S. ARNOTT.

CAMPANULA KEWENSIS.

AMONG the numerous pretty and choice harebells suitable for the rock garden C. kewensis occupies a high position. It blooms during June and July, and is a hybrid between C. excisa and C. arvatica, having originated in the rock garden at Kew. The plant is a good grower, and in stony soil it has spread rapidly, covering several square feet in three years. It is fairly intermediate between its parents, and bears a large number of open flowers similar to C. arvatica. The colour is a fine violet-purple, and the blooms are produced on wiry stems about 4ins. high.

This season the plant has been exceptionally fine, and has fully upheld the high reputation it has so deservedly gained. It is readily increased by division, and in congenial surroundings it will soon make progress. Certainly wherever alpines are grown this delightful little subject should be represented by one or more plants.—T. W. B.

NEPETA MUSSINI.

FEW plants suitable for growing in the rock garden have had a greater call upon them during the last few years than Mussin's catmint. It is a subject one meets with everywhere, flowering well in a period of drought and, once established, will go for years without need for disturbance, unless it be to restrict its boundaries. I find that the end of August is the best time to propagate it from cuttings, as then there are plenty of shoots available from the base of old plants. These can be dibbled in the ground, assisted with a little sand, and soon take root. It is hardly necessary to protect young ones during winter except during long spells of frost, as by October they are usually well established and able to take care of themselves. If plants are to be moved, it is best to do so in March and not in late autumn. For edging to garden paths Nepeta Mussini is much used to-day, and cuttings inserted where they are required to remain if taken in August or early September do not often fail.—W. LINDERS LEA.

CROCUS TOMASINIANUS.

MANY delightful flowers offer themselves to us among the species of crocus, as distinct from the glorious "Dutch" varieties of C. vernus, which make our gardens glow in the spring with bright colours. I venture to bring before your readers the delightful C. Tomasinianus, a truly delectable spring-flowering species, which does not rest its claims upon size, but upon its great beauty and ease of cultivation. Planted in the grass, in the rock garden or border, it gives us its charming pale sapphire-lavender flowers in March, and, as it seeds freely and self-sown seedlings come up readily, it will, in time, afford us many pretty features, devoid of stiffness and appealing to us because of the natural manner in which these self-sown plants scatter themselves about. It is a native of Servia and Dalmatia, and bulbs, or rather "corms," can be procured at a cheap rate in autumn and planted at the same time as other crocuses, and at a depth of about 2ins. in light soil in a sunny place. The flowers, though not large, are extremely pretty and the sapphire-lavender of the type is varied by a number of varieties which have been separated, but which generally come among the self-sown seedlings. We have, for example, the clear lilac C. T. atropurpureus, and the light lilac C. T. pallidus, as well as white, amethyst and other colour tones. C. Tomasinianus is one of the freest and best of the spring-flowering species of crocus in commerce and can be confidently recommended for planting and leaving to look after itself.—DUMFRIES.

MIMULUS CUPREUS.

MIMULUS CUPREUS is a well known plant which has proved its worth in the garden for a good many years. I have here what everyone who sees it admires and comments upon as a very fine variety or, possibly, a hybrid of M. cupreus with another species. I saw it in a garden at Wanlockhead, reputed to be the highest inhabited village in Scotland, and through the kindness of Mr. Watson, the owner of the garden, a true flower-lover, became the happy possessor of a small plant from his clump. Planted in a shady, rather damp border here, this has grown apace, and, although some pieces have been taken off to plant in other parts of the garden, this small plant has become a mass fully 5½ft. in length by 4ft. across. It is a gorgeous sight, and in this brilliant weather, when the sun is upon it in the early part of the day, it seems to be glowing with "fervent heat." When the sun is off it is more restful. We want more hardy mimuli which will endure in the garden for years and spread into masses like this.—S. A.

SIDALCEAS.

SOME very beautiful varieties of sidalceas have been raised and distributed within the last few years, and a sowing made from seed saved from any good strain can be relied upon to produce good results. They are most useful plants for the hardy flower border where warm colours are desired, and it is now possible to have them in all tones of light and deep pink and mauve. In height they range from 2ft. to 5ft., making it possible for them to be so disposed in the border as to enable full advantage to be taken of their effective spikes of bloom.

Among the named varieties that have come under my notice recently the following is a quartette of really outstanding merit:

S. Listeri.—This is a charming variety bearing flowers of palest blush colour. The stems are strong and erect, and the foliage is most distinctive and semi-glaucous. Plants of this variety when in flower are about 2–2½ft. in height.

S. Sussex Beauty.—The flowers of this variety are of somewhat stronger colour than the foregoing. It is a most graceful and distinguished-looking plant, with flowering stems some 4ft. in height.

S. Mauve Queen.—A really magnificent sort, the flowering stems of which are 5ft. tall and upwards. The flowers are of a pleasing light mauve colour. Grown in clumps of half a dozen plants, this variety is majestic in appearance and a worthy addition to any garden.

S. Pink Pearl.—As the name indicates, this is a variety the flowers of which are pink in colour. It is a very pleasing tone of pink, and can be regarded as one of the very best sorts of this particular colour. It grows about 3ft. tall.

All the above sorts are most distinctive in appearance even when not in flower, the foliage being very handsome, and in the ordinary way there is no need to resort to staking and tying when the plants are in flower.—HOWARD H. CRANE.

SIMPLE GARDENING

POTTING FREESIAS, CHIONODOXAS AND SCILLAS.

THE fragrant flowers of freesias are produced from very tiny corms, and are, in consequence, suitable for growing in small pots or for massing in large ones, pans or bowls. Some really charming colours are now available, a few of them being Jubilee (white, tinted pink; this is suitable for small pots or low bowls), Mouette (another white, tinged pink), Treasure (a large yellow), Merry Widow (dwarf lavender), Conquest (rose pink, beautiful in masses), Buttercup (pale primrose, early) and Golden King (late). A good general compost is formed of the following: Loam, 2 parts, leaf-soil 1 part, peat 1 part, and coarse clean grit to make all porous. Manures are not needed. Very frequently one sees freesia plants on stages and greenhouse shelves with their stems and main leaves toppling over the sides of the pots; this is the result of bad potting and wrong treatment after the growth begins.

Usually, the small bulbs are planted in the soil in the pots with the tops visible, and the new growths are weakly from the start. I prefer to bury the bulbs 1in. below the surface; the new stems grow just the same, but come through the soil much stronger. Also, it is wise to grade the bulbs and to plant the tiny ones in separate pots, not mixing them with the larger-flowering specimens. Do not re-pot, but plant just the number of bulbs in each pot, and not more than can find room to grow. When potted, water, allow the pots to drain, plunge under ashes or sand (which is better), and treat similarly to other kinds of bulbs so plunged. The other kinds of bulbs may be treated in a similar way, but look best in bowls and pans.

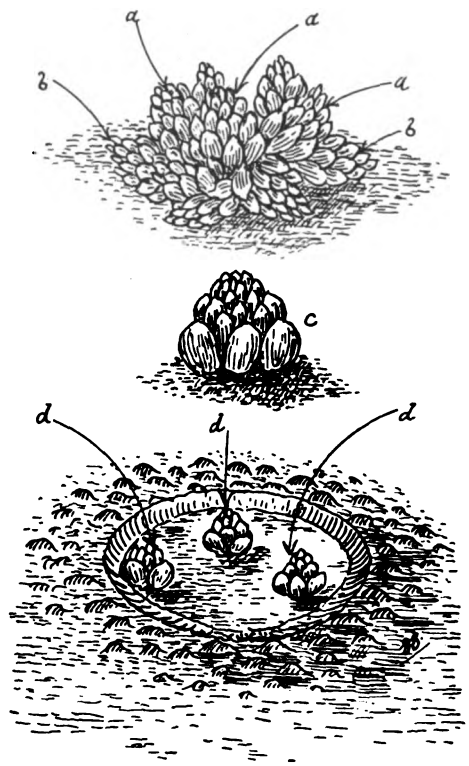
BLANCHING ENDIVE, CELERY AND LEEKS.

These three kinds of plants are not much appreciated unless they are blanched and tender. The harsh taste of the green, unblanched specimens is absent when they are properly treated at the right time. Unblanched lettuce can be eaten, and frequently is, without comment; but endive must be rendered tender and palatable. At this season lettuces soon decay, and often more so as the autumn dampness comes, while the endive plants thrive and resist open dampness and rather severe frosts. Probably many readers have batches of endive in their gardens now, which may be ruined if not properly treated. The plan of laying on slates, tiles or boards is generally adopted, and with disastrous results, as the hearts, instead of blanching, rot away. This condition results from confining the moisture. Exclude light but not air, then blanching will result and leaves will not be lost. I find the best way to secure this condition is to lay down some pea-sticks, flatwise on the plants, and then some bags or mats with boards or bricks to keep all in position. Not only the inner but the outside leaves too will blanch beautifully.

With regard to celery and leeks, it is very important that the leaves be kept upright and all foreign matter excluded from the centres of the plants, or decay may set in when the matter becomes moist. Do not rely too much upon paper bands, but mix together sand and fine ashes, placing these next to the plant and ordinary garden soil outside it, blanching as the plants grow and feed at the same time. Slugs must be excluded.

PLANTING LILIUM CANDIDUM.

In many cottage gardens this charming lily may be seen in robust health and flowering freely. In other gardens one sees the plants just existing in a distressed condition. In the same garden the plants will do well in one quarter and fail in another. Generally, the bulbs



do not like being disturbed much and, unless it is absolutely necessary to lift and replant those that are succeeding, it is well to leave them untouched. But many cultivators wish to plant bulbs who have not as yet grown this lily. The soil should be well drained, deeply dug and well rotted manure mixed with it, and, if quite convenient, this work should be done several weeks prior to the date of planting. This cannot be done in every case, so I advise the cultivator to place 3ins. of unmanured compost immediately below the bulbs and to bury the latter about 4ins. deep with open soil not containing any manure. Search all new soil for wireworms, as these are destructive to the plants. Be sure that the soil is well drained and that old, used composts are not employed again. If old clumps must be lifted and the bulbs separated, grade the latter, using the best, *a*, *a*, *a*, replant them in the same place and the weaker ones, *b*, *b*, in another. The bulb, *c*, is a good one, and such should be planted as shown at *d*, *d*, *d*, allowing a space of 9ins. between the bulbs. Mark all places with labels or neat sticks. Do not expose bulbs one minute longer to the air than is necessary.

WALL AND PILLAR PLANTS.

When the plants are flowering or bearing a wealth of young leaves, brightly coloured and fresh, they are cared for, trained, cleaned, fed and watered. But at this season of the year we sometimes neglect the plants very much, and then they quickly become an entangled mass of shoots, especially those that are of a true climbing or entwining nature. Roses should be the first on the list to receive full attention now; the shoots that are to bear the harvest of blossom next year should be freed of all others not required at an early date, so that those retained may ripen properly. Remove the older branches, cutting them off near the base, and retain the younger ones their full length, then a useless late growth of tiny shoots will not occur.

The time to remove the unripe tips of the young shoots is in the spring—at the end of February, when all danger of severe frost is past. The different sections of clematis should be dealt with according to their special requirements, but undue delay should be avoided. Straggling shoots of ivy may be cut now, but a general cutting should take place next spring. Honeysuckle plants frequently become top-heavy; all specimens found in such condition now ought to be judiciously thinned out. These hints apply also to jasmines. Plants of the vine family should be examined now with a view to pruning late in November.

GARDEN PATHS.

Paths that dry quickly after a heavy shower of rain are pleasant to walk on; those that retain water on the surface for a long time afterwards show plainly that the drainage is, mainly, at fault, and this fault may be accounted for, generally, in two ways, ground naturally low-lying or badly constructed paths where surface drainage is normal. Some paths, not satisfactory now, may be put right by simply turning over the surface, raking and rolling it. Others should be turned entirely, taking care to retain the drainage portion in the bottom. All coarse, tap-rooted weeds should be extracted when the path material is turned; this care should be taken when new paths are constructed. If crazy paths are preferred without plants growing on them, after laying a good base of concrete, 1 part cement and 4 parts sand, lay pure cement 1in. thick on the surface, using laths of that depth to form the divisions when actually laying the cement, but withdrawing them before the cement sets and as the work proceeds. If plants are to be grown, leave wider spaces to contain a small quantity of soil, and drop little dabs of coarse, sifted sand on the cement before the latter dries, it will then have the appearance of a stone surface more roughly hewn. INSECTS, ALIAS BUGS

SO much is written in the horticultural Press about garden pests, and so little about pests which attack humans, that I think it only fair to give them a short note. Gardeners swear and curse in private over aphis and slugs and other creeping, crawling and flying insects which damage their plants: they also write to us about them with great bitterness. Presumably, every gardener has a skin which is capable of irritation. He may scratch and swear in private, but never a chirp comes from him in public, which gives the attacker an unfair advantage.

I am no entomologist; on the other hand, I have a tender skin, and so consider myself an expert in insect bites. The Americans have a useful name for insects: they call them "bugs," presumably because they are suspicious of all insects until they have proved them to be harmless. This is a useful maxim and one which should be followed through life. Personally, I divide all bugs into two classes—those which are capable of biting me and those which are not. With the exception of the bee and the ant, one of my main objects is to slay the former before they can perforate my skin.

Of flying bugs the sorest bite is that of the wasp, the most irritable the mosquito, and the most annoying the midge. The wasp is comparatively large and, unless annoyed, rarely attacks you; therefore the obvious thing to do is to slay it when you have it cornered and to leave it severely alone when the chances are against its successful execution. If you are bitten, Scrubbs ammonia is the best salve, or, if a very bad sting, a hot compress. In THE GARDEN of June 27th, 1925, there was an article on Mosquito Control in Gardens, where the author sets out the various form of mosquito. The anopheles, one of the malaria mosquitos, can be recognised by the fact that when he squats his nether quarters point towards you. There are, however, many other kinds of biting gnats, and the best way is to kill anything that pings. I have had considerable experience of mosquitos in the tropics and elsewhere, and I have never found any of the so-called preventive lotions very efficacious. The main constituent of these lotions is usually either oil of lemon grass or oil of eucalyptus. Probably ordinary eucalyptus, such as is used for colds in the head, is as good as anything. As a cure for the bite, ammonia is good, but iodine is much better and is really a sure cure, provided that it is applied as soon as the bite is felt. I have never known a mosquito bite bother me an hour after applying iodine.

The midge is apparently universal, and I do not know if they are worse in the hills in Burma or at Loch Maree on the west coast of Scotland. A mosquito may be solitary, but if there is one midge there are always thousands. They are so small that it is impossible to flap them away. In really bad midge areas you can wear a fine veil, but it is a hot and stuffy contraption. A midge bite does not last long, but while it does it is both sore and painful. When they are bad it is impossible to anoint every bite with iodine if you pay any attention to your appearance, and no preventative except a coating of tar keeps them off if they are really voracious. Extract of witch hazel helps to remove the irritation.

I have kept what, to my mind, is the worst of all human pests to the end, an atrocious beast of which I have never learnt its proper name, but which is known in various parts of the country as the gooseberry bug, the berry bug, the bracken bug and the harvest bug. Luckily, it only exists in certain districts; unluckily, my garden is in the middle of one of them. Apparently, it is a red mite which is only just visible to the naked eye against a dark cloth, so small is it. Kind people say that it does not try to harm you, but, finding itself in a strange environment on your clothes, it burrows in order to escape. At any rate, it burrows under your skin and, dying there, sets up a bite like a flea's but twice as irritable. It is a curious fact that it always attacks you when your clothes are tight. If you wear a belt, your middle will have a row of spots, and they love the flesh behind sock-suspenders. The obvious thing is to take off your sock-suspenders and loosen everything all round. A good preventive is to rub yourself all over with liquid Sanitas before you go out into the garden: it is quite harmless to the skin. Iodine is also a cure for this bite, and in a lesser degree ammonia. One other tip: if you must scratch, use the back of the nails and you do not tear the skin.

Gardeners are a long-suffering race. They have irritation of the mind from insects which attack plants, and irritation of the body from bugs which attack them. E. H. M. C.

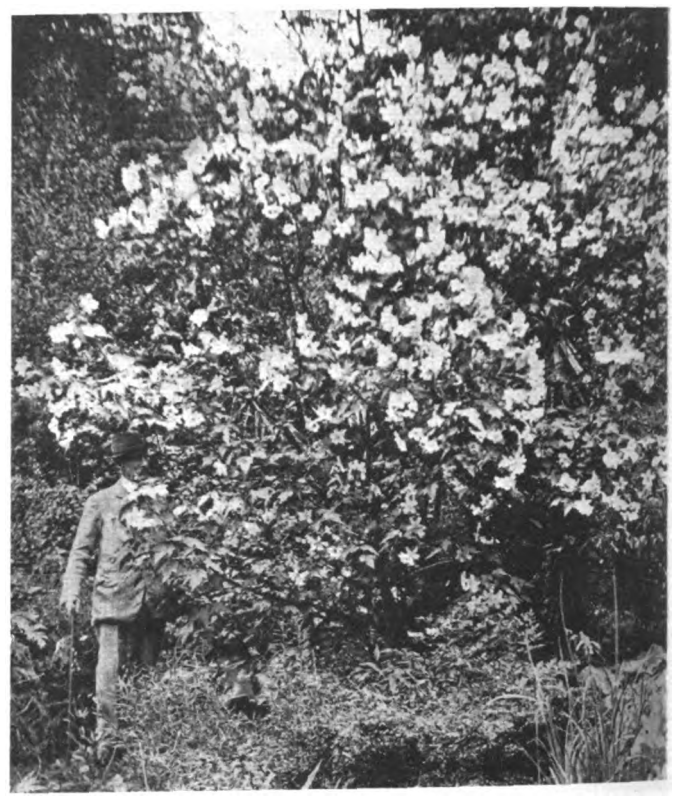
GARDENING in the WEST of SCOTLAND

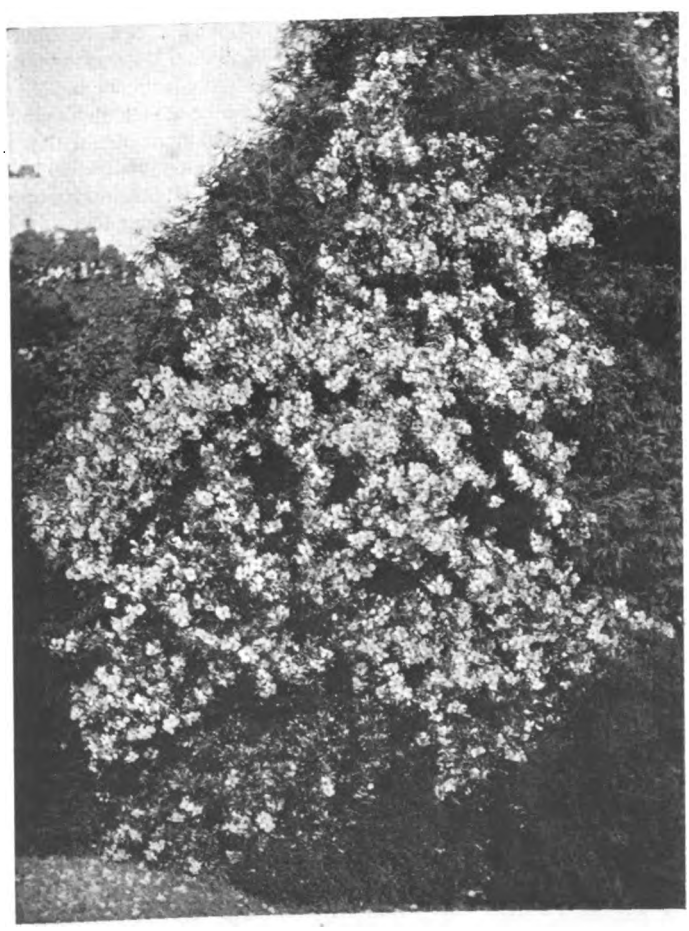
BY SIR HERBERT MAXWELL, BT.

WE used to be instructed by writers on horticulture to esteem the more northerly parts of the British Isles as less favourable for the cultivation of half-hardy exotics than the southern counties of England. We in Scotland, for example, were wont to listen with awe, not unmixed with envy, to descriptions of what had been achieved in some gardens of Cornwall, and very few of us attempted to emulate those results until we realised, not many years ago, that British climate varies far more according to longitude than latitude, and that all along the west coast as far north as Ross-shire, wherever protection from searching sea winds can be had, many shrubs and herbs flourish vigorously which it would be futile to plant out in Norfolk or Warwickshire.

It is true that there is stronger sunshine, and more of it, on the south coast of England than there is, say, in Argyll, and that sun-loving plants from South Africa, Asia Minor and Australia are more likely to succeed there than under the cloudier skies of the north-west; but, on the other hand, there are many exotics, especially from Chile and from high altitudes in Asia, that relish plenty of moisture and shrink from strong, prolonged sunshine. For instance, I have never happened to see a decent bush of Desfontainea spinosa in Cornwall. Quite possibly I may have missed or forgotten good ones, although the owner of one of the largest collections in that delightful county tells me that he has planted it repeatedly without success. Seventeen years ago I measured a specimen of Desfontainea at Stonefield in Argyll, growing near the foot of Eucalyptus Gunni 80ft. high. This bush was 14ft. high and 75ft. in circumference, notwithstanding that one side thereof had been ruthlessly cut back to clear a gravel path. There is a considerably larger specimen at Corswall in Wigtownshire, but its environment prevents accurate measurement being taken.



ABUTILON VITIFOLIUM AT MONREITH.



A FINE PLANT OF EUCRYPHIA PINNATIFOLIA.

It is, however, about Scottish facilities for growing Asiatic rhododendrons that we have been so slow to learn. We neglected the few examples that have long been patent, such as Castle Kennedy, where R. arboreum, niveum, barbatum, fulgens, campanulatum, etc., raised from seed provided by Sir Joseph Hooker seventy years ago have grown into magnificent specimens; or Stonefield, where Dr. Campbell, founder of the sanatorium at Darjeeling, planted the noble R. Falconeri and grande to be seen there at this day.

"In Scotland," wrote Mr. J. G. Millais, "where conditions on the west coast are, I think, even better than in Cornwall, there are but few gardens devoted to rhododendrons. . . . Western Argyll and Dumbartonshire should be one beautiful garden, as most moisture-loving shrubs find a congenial home there. . . . At Ardarroch (Garelochhead) there are plants of R. arboreum up to 24ft. in height, and R. campanulatum seeds itself there as freely as in the Himalayas." ("Rhododendrons," pages 70, 71.)

We Scottish amateurs have, indeed ourselves to blame for not having discovered the capabilities of our western climate long ago. Now that we have done so, we can start on even terms with our south country friends in dealing with the vast number of new species of rhododendron which have been introduced since the beginning of the present century. Abundant rainfall and a humid atmosphere in summer are all in favour of the genus; indeed, we have but two adverse conditions to contend with—violent winds, especially from the north-west, and liability to late spring frost, so fatal to the precocious growth induced in some species by high winter temperature.

The besetting sin of flower gardening being sameness, it should be the aim of every amateur to give his borders and shrubland a character distinctive of the capabilities of his soil and climate. West Country gardeners would do well to give more attention to plants from Chile, for there is much similarity in the climate of that country south of Valdivia to that of our west coast. Mention has been made above of Desfontainea; to name some other treasures from that distant land, there are several huge specimens of Eucryphia pinnatifolia

Digitized by Google

at Poltalloch in Argyll; and at Castle Kennedy in Wigtownshire E. cordifolia 25ft. high is a formidable rival to the famous growths of this species at Nymans. The late Mr. R. Birkbeck at Kinloch-Hourn and the late Mr. Osgood Mackenzie at Poolewe had luxuriant growth of tricuspidaria, mitraria, embothrium, Abutilon vitifolium and (against a wall) megapotamicum, several species of fuchsia, Solanum crispum and jasminoides, Lomatia ferruginea and escallonia; and there are hundreds of gardens between those northerly stations and the Mull of Galloway where these fine plants and many others from the southern temperate zone would flourish freely. It vexes one to see ground admirably suited for them stuffed with common nursery stock.

OLEARIA MACRODONTA, ONE OF THE FINEST OF THE GENUS.

Many fine trees and shrubs make themselves as much at home on any part of our west coast as in their native New Zealand, especially if they have been brought from the South Island, and most of them have the estimable faculty of resisting wind—nay, really rejoicing in plenty of it. I need not add anything to the notes on olearia species submitted in THE GARDEN of July 25th; but in another genus of Compositæ—senecio—there are several fine species that takes as kindly to our soil and climate as does their poor relation, our native groundsel. S. Huntii, which may grow 20ft. high, and S. Greyii of humbler stature, both sheet themselves with panicles of bright yellow flowers in July. S. Hectori is less hardy, but stands moderate winter cold very well. It is well worthy of a sheltered place, both for its white-rayed flowers and its great bright green leaves, which have the peculiarity of being pinnate at the base of the broad blade. Plagianthus betulinus and P. (Gaya) Lyallii present a lovely appearance in July when sheeted with milk white bloom, coming after the several species and varieties of leptospermum.

If New Zealand had sent us nothing but the "Red Kowhai" (Clianthus puniceus) we could have asked for nothing finer than that gorgeous shrub. Although it comes from the North Island, where the late Mr. Cheeseman described it as nearly extinct in a wild state, the shelter of a wall carries it safely through all but the more severe of our west country winters, and if hard frost in March should destroy the early bloom, there are always plenty of flower-buds to renew the display later. A fresh stock may be maintained from the seeds, which are freely produced. Last, but not least, let not the so-called "New Zealand cabbage" (Cordyline australis) be neglected. It may grow 40ft. high, and avenues thereof form one of the most notable features in the great collection at Logan.

I have enumerated but a small fraction of the exotics at our disposal, but the list may serve as a stimulus to encourage enthusiasts in western Scotland to take fuller advantage of their climate by following the spirited lead set by Cornish gardeners.

NOTES OF THE WEEK

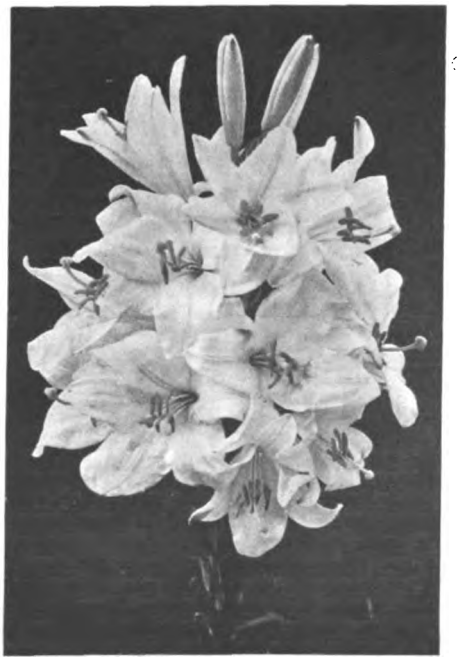
EUCRYPHIA PINNATIFOLIA.

I HAVE lately examined a number of bushes of various sizes of Eucryphia pinnatifolia in a friend's garden and can bear out the facts of the note published in THE GARDEN of January 19th, 1924. This note was by Mr. W. Slinger, of the Donard Nursery Company, who has had as much experience as anybody with this fascinating plant. In it he pointed out that there was various forms of E. pinnatifolia, some of which were widely divergent in growth, some forms making only stunted growths, while others grow over 12ins. every year.

The bushes in my friend's garden show this variation of growth very clearly, but they also show another fact, that bushes with a leader grow better than those without one. I believe it is a fact that gardenia cuttings which are taken from a leader grow far faster than those taken from a cutting off a horizontal branch. Perhaps the same factor applies in the case of E. pinnatifolia. It would be interesting to know if any reader of THE GARDEN, who has had experience in propagating this plant, can tell us whether this is so or not.—E. C.

LILIUM CANDIDUM: ITS LIKES AND DISLIKES.

IT is, I think, generally agreed that among lilies, candidum is the most popular of all for the garden, and further, when bulbs have been planted at the right time—which is immediately the flowering stalk has died down and before new growth emanates—they stand a much better chance of getting established quicker, than when, as is sometimes the case, planting is deferred until autumn. Again, it is recognised by all who have to do with this peerless lily, that once they have made themselves at home in the garden, it is a mistake to meddle with them. These facts are, I venture to say, fairly well known, but I do not think that it is sufficiently appreciated how vital a sunny position is to the well-being of the bulbs. A leaf out of the book of one's own experience will confirm this. A clump of candidum in my garden had never failed to bloom for many years until one summer it became necessary to extend a pergola over the border in which the lilies were quartered. A wichuraiana rose soon enveloped the structure, and resulted in loss of light to the lilies below, so much so that for a couple of seasons they bloomed scarcely at all. Eventually the addition to the pergola was taken down, sun and air reached the bulbs as previously, and full blooming power was re-established. If ever a lily showed its resentment at being shorn of its "place in the sun," that lily did!—W. LINDERS LEA.



A FINE HEAD OF LILIUM CANDIDUM.

GALEGA HARTLANDII.

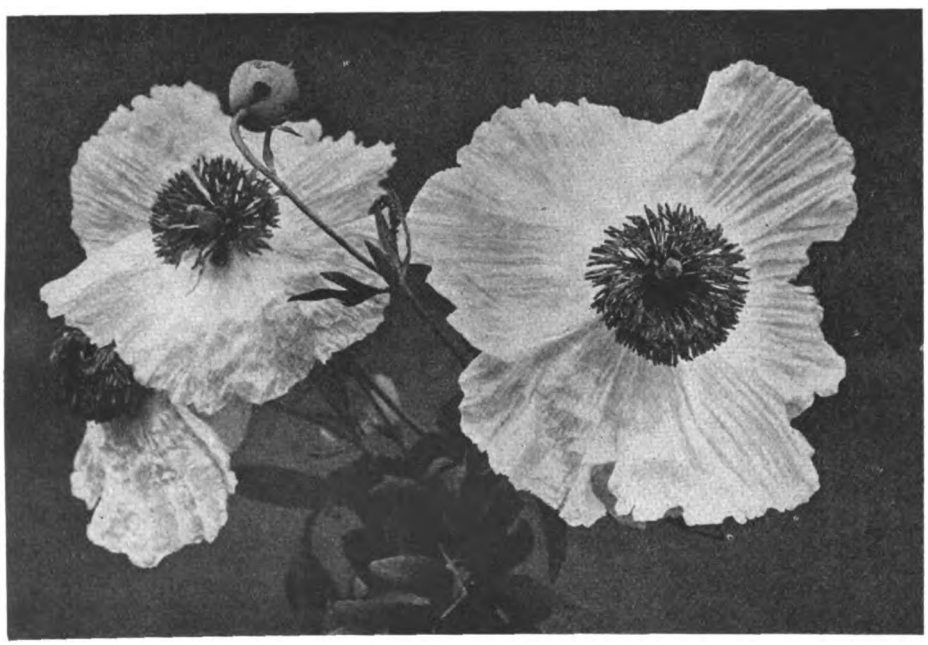
THE late Mr. W. Baylor Hartland of Cork was responsible for the introduction of the goat's rue, which bears his name, and I have still in my garden a plant which he very kindly sent me at the time it was distributed. It is said to be a form of Galega flexuosa, and the character of the stems would appear to justify this statement. Its main feature in the early spring is that it affords us a good plant with warm, variegated foliage. Later in the season the variegation is practically absent, but in late summer and autumn the

Digitized by Google

plant is laden with its sprays of pleasing lilac-purple flowers of the arrangement and form so characteristic of the galegas. It varies in height but in a dry border here it is at present about 5ft. high. I have had it less and also more, but from 4ft. to 5ft. may, I think, be taken as its normal stature. As a border plant G. Hartlandii is excellent, absolutely hardy and apparently satisfied with almost any soil likely to be included in a garden. It has been said that it does not come true from seeds, so far as the variegation is concerned, but this is not absolutely correct, and I have had a good many self-sown seedlings as pure in their variegation as the parent. On the other hand, some plants had the ordinary green foliage of the typical G. flexuosa.—S. ARNOTT.

ROMNEYA COULTERI.

VERY different impressions seem to be abroad as to just what this plant looks like, although all are agreed as to the flowers and their resemblance—at a distance, at any rate—to poached eggs. The height, however, does differ, according to the time the plant has been established and the nature of the soil. If you have only seen dwarf specimens about 2ft. high, it should be remembered that it is possible to grow them 6ft. high, and as much through, with many-branched stems furnished with glaucous foliage and giant pure white satiny flowers with golden centres, produced from June to September.



TYPICAL BLOOMS OF ROMNEYA COULTERI.

Unfortunately, the plant is not a reliably hardy one and extra care has to be taken in preparing its home, if anything like justice is to be done to its capabilities. It does not seem to be a matter so much of cold as damp that proves injurious during the winter, and I have seen magnificent specimens growing in very cold parts of the country, where steps have been taken to guard against winter damp.

First of all, then, let us see to it that the position is a very sunny one, preferably facing due south and protected on the north and east by a belt of shrubs that will screen from cutting winds. The soil needs careful preparation and a deep pit should be taken out and filled with rich sandy loam. Do not stint the size of this hole—6ft. square and 4ft. deep is not at all excessive where a really fine specimen is to be gradually built up. It is a mistake to raise this bed higher than the surrounding ground, for the roots demand large supplies of water during the summer and especially appreciate liquid manure. Planting is work that demands considerable care, for it is of the highest importance that the roots should not be damaged in the slightest.

Propagation is usually effected by seeds sown in single pots as soon as ripe, and the small plants should be grown on in these for twelve months before planting out. When planting, simply take out a hole of sufficient size and depth to contain the plant, break the pot by a sharp blow from a hammer and take away the broken pieces, then fill in with soil and firm carefully. In this position the plant will spend its life, for it is impossible to transplant with any hope of success. The plants will come safely through all ordinary winters, but need a covering of litter or ashes during times of severe frosts. Many failures are experienced where the mistake is made of keeping on this covering permanently throughout the winter, instead of using only when occasion demands. Permanent covering encourages early growth, and this is, naturally, far more tender than if it had been uncovered all the while.

Where the seasons are poor and seeds do not set freely after flowering, an alternative method of reproduction is by taking root cuttings. Stem cuttings are extremely difficult, for, although they will remain fresh for a long period, they simply will not form roots. To procure root cuttings, carefully remove the soil from the surface until these are exposed, then cut off the roots with a sharp knife and insert the pieces about 3ins. long in very sandy soil over a gentle hotbed. This should be done early in the year. —H. W. C-W.

NEW FLOWERS.

THERE is a wide field, as regards new hardy and half-hardy flowers, for English horticulturists among the wild flora of Kenya Colony. There are many beautiful tropical flowers, too, but with them I do not intend to deal to-day. Some of our beautiful indigenous flowers have already been introduced and many more await an introduction.

The thunbergias are among our most prized possessions and thrive even in cold soils in England till the frosts cut them down. Several of these are climbers, one is a gorgeous golden orange, another the colour of the moon in eclipse, another pure gold with a purple centre. There is a deciduous bush variety, deep purple with a yellow throat, and a herbaceous plant with the most wonderful blue corola and also some pale yellow ones.

Some of the delphiniums have been sent home, but I have not heard yet what luck has resulted. One of them is a heavenly thing, pure white of the butterfly type. I shall never forget my first glimpse of it. There appeared to be acres and acres of it, as far as one could see, lovely spikes of butterfly-poised flowers standing above the short green grass. Another, with Liberty shades of blue and green, grows just beyond the Kikuyu forest. Many of the flowering stalks are 4ft. and 5ft. high, and below them grows a most fascinating coral-coloured styarium, and above them all a wonderful senecio. But to return to the delphiniums, there are others of wonderful shades of blue. There are also one or two aconites.

Our gladioli have perhaps received more attention than most of our wild flowers, and there are several varieties, of which I have four or five established in my garden now. I have only once found a pure yellow variety, of which I failed to get bulbs. A subsequent visit to the same spot revealed a maize-shamba and no sign of the beautiful yellow gladiolus. The crinums are perfectly wonderful, transplant easily, and improve considerably under cultivation. Their scent is as delicious as it is powerful, and a bed of crinums soon contradicts that absurd idea that African flowers have no scent. Another bulbous flower is the beautiful scarlet zephranthes. I have dug down more than 2ft. sometimes in search of its bulbs and this fact may be of interest to those who are trying it in England. Shallow planting is not likely to suit it.

Of wild clematises I have collected three. They are all white. One is very like the Traveller's Joy of the English hedgerows, another like a C. montana, and a third as big as a purple Jackmani with wonderful large waxy white flowers.

Succulent flowering plants or rock gardens abound and one of my happiest finds was a pure white mesembryanthemum. There are heaths and giant lobelias and groundsels on the higher slopes of Mt. Kenya, climbing begonias in the forests, balsams and powder blue salvias, and other things too numerous for the space of a brief article.

Some of the crotalarias are worthy of cultivation in their present state and I am sure would repay careful attention and possible crossing with other varieties. There is one asclepias that is more beautiful than any I have seen in cultivation at home and better than any of the varieties we have been able to import. Hibiscus, we have, of course, in great variety, and some that have been introduced to home horticulturists are doing extraordinarily well.

The geraniums are fascinating—I use the word in an unbotanical sense, I am afraid, and include pelargoniums. One of the most exquisite ones is Geranium aculatum, the most wonderful dusky ducks-egg green you can think of or imagine. Another is cherry colour and a third pure white. I have an interesting seedling, the parent plant is the dusky green and the pollen plant is the cherry variety and the seedling is deep cerise, with a hint of darker shading.

Polygonums abound in great variety, and among the rumex there is a very striking climber whose coral coloured festoons of flowers quickly cover any bush or building near. The lantanas are interesting, too. One has whorls of scarlet and yellow flowers and another shades of mauve, yet another white and green flowers, etc.

Of the many striking and beautiful flowers of the compositæ, the scrophulariaceæ, and the labiatæ, I hope I may be permitted to write another day.—LUCY LANGRIDGE.

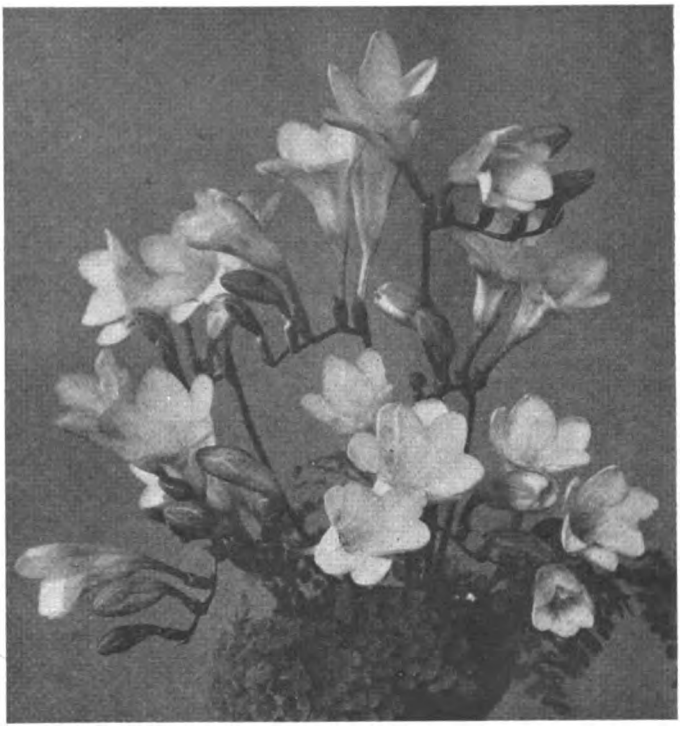
FREESIAS ARE GENERAL FAVOURITES

IF ever there has been raised a new race of flowers that has soon become a general favourite, freesias rank first. It is only a comparatively short time ago that the first new break, Freesia Tubergeni, the result of a cross between F. Purity and the Cape species Armstrongi, made its appearance, and in the course of a very few years such improvements have been made in size of the individual flowers, as well as in the colours, that the first new-comer can scarcely be recognised now and is only kept as a curiosity. As far as mauves, carmines and the so-called blues are concerned, it can safely be stated that Armstrongi has influenced these crosses, whereas the best yellows and oranges originated by crossing Purity with Chapmani, the origin of which is unknown to me. The suggestion that F. aurea from the Cape has been one of the parents had to be abandoned, as the flowers of this species are very unlike any freesia, being very small and inflated and having three vivid orange blotches at the tips of the corolla. All varieties that I raised by aid of F. aurea distinctly bore these characteristics, and not one F. Chapmani ever appeared among them. Perhaps Mr. Chapman, the raiser, will oblige readers of THE GARDEN by shedding some light on this puzzle and say what species or varieties he used to obtain the uniform deep yellow in his namesake, which, very small-flowered as it is, has an undeniable charm on account of its fine shade of colour.

As most of the varieties which had their origin in the Zwanenburg Nurseries have been shown in London by that enthusiastic exhibitor, Mr. Dalrymple, it is not on my way to sing their praise in these columns, as good varieties besides mine have now come to the front, last but not least that fine blue acquisition baptised Wistaria. It is a pity that no other name could be chosen. It always seems to me rather a wrong method to employ a Latin name of another flower that has nothing to do with the new one.

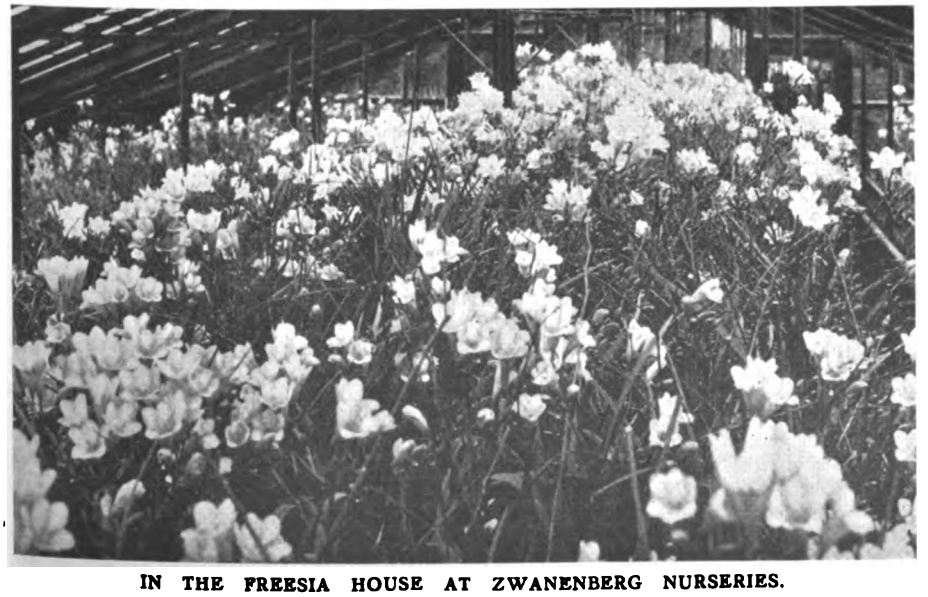
Freesias are of the easiest imaginable culture, and although complaints sometimes come in that leaves only and no flowers have been produced, these failures are invariably due to unsuitable treatment and through the desire of having them in flower at a premature date. The accompanying illustration shows one of my cold houses devoted to freesias, planted at the proper time and treated as they should, flowering about the beginning or middle of March. After having been harvested in July, the corms must be kept absolutely dry and in a temperature of 70–75° Fahr. until the beginning of September, when the corms show signs of root action. Planting, if at all necessary, can be deferred until October, but I do not recommend this, as by planting so late growth is uneven and a few of the plants will be in flower when the great percentage are only showing buds.

Suitable soil is a mixture of old well-decayed leaf-mould, some old perfectly rotten cow dung, a fair sprinkling of sharp silver sand to keep the compost porous and open, and some bone-meal or pulverised mortar rubbish. Pots of 4–4½in. diameter, five to six corms according to size must be taken,



ONE OF THE BEST OF ALL FREESIAS, APOTHEOSIS.

and these covered up with soil so as to have the tops just under surface level. In case the soil is dry, give the pots a good soaking and put them under cold glass, where they start very soon and make rapid growth. Freesias evidently like a genial atmosphere to start, and if thus treated, after the roasting before planting, the much-dreaded "duds" will not appear and development is quite normal. As soon as cold, wintry weather sets in the next move is to the house, where they are intended to flower, and which must be kept as well ventilated as possible. What freesias, as all Cape bulbs, greatly dislike is a close atmosphere, and if the temperature sinks as low as 35° or 36° Fahr., it will not do any harm provided the air is not laden with moisture. To avoid this, it is a good plan to let the hot-water pipes circulate on dull, sunless winter days and open one or two of the windows so as to stimulate air circulation and purify the atmosphere. Temperature must be kept up from 50° to 55° Fahr., not more, and as soon as, in early spring, the sun attains more strength no artificial heat is at all necessary.



IN THE FREESIA HOUSE AT ZWANENBERG NURSERIES.

Freesias can stand any amount of sun; in fact, do not flourish without it, and when in full growth like much moisture at the roots. As soon as the flower-spikes appear a dose of weak liquid manure will work wonders by giving strong, thick stems and highly coloured flowers.

There is little doubt that although the freesia is already a general favourite, it will become one of the most popular flowers for spring decoration. Apart from its great decorative value, it gives the maximum of effect with little waste of space that is valuable, and very little attention.

C. G. VAN TUBERGEN, JUN.

ROYAL BOTANIC GARDEN, EDINBURGH

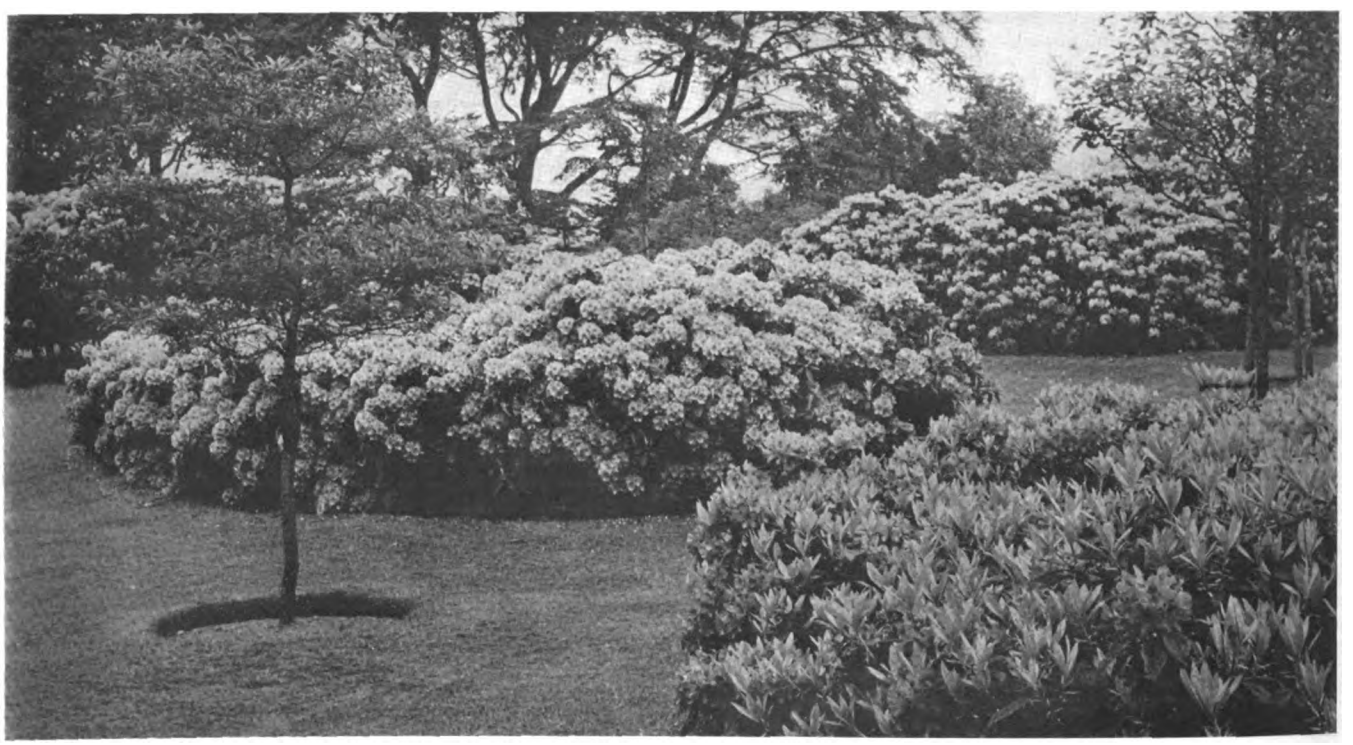
BY R. L. HARROW.

THE bright, sunny days of June and July, after the heavy rains which we experienced during May, has this year been favourable for the production of fine foliage, and also the free flowering of many plants in the Royal Botanic Garden, Edinburgh, and the east of Scotland generally.

This has been specially noticeable in the rock garden, where the plants have revelled in the sunshine, and the general appearance in May and June was one of rich colour, with the number and variety of species in flower. Meconopsis are among the attractions to be looked for here. Of those lately flowering, M. latifolia is the species most generally admired, and is certainly among the best of those for giving a succession of flowers late in the season. Self-sown plants in large numbers appear in the crevices of the rocks, among other inmates, and require no special attention, giving a rich harvest of Cambridge blue flowers. This species is seldom raised from seed artificially so abundant has it become in the rock garden. M. Prattii also sows itself very freely, and is now producing flowers of a surprising variety of colour. Among them are dark blue, chocolate and white, which are outstanding in their hues. Among the disappointments, up to the present, are the colours of M. speciosa, as they are at present cultivated here. They show none of the fine blue tones described by their collectors. Other species that have flowered are M. impedita, M. aculeata, M. grandis, M. simplicifolia, Bailey's form, and M. integrifolia, in its varied forms, all of which are beautiful in their season. There are still several good primulas to be seen, among the most attractive being P. Littoniana, in a good sized clump, the bright scarlet calyces of the unopened flowers being so distinctive in this remarkable species. The microforms of P. capitata are also coming to their best, the finest being perhaps, P. Mooreana, with its large dark bluish flowers aggregated at the end of the silvery scape. Another primula which should be grown by lovers of this genus is P. nutans. This species requires a shady, moist position to secure good results, and will well repay any trouble taken, as when well grown and in bloom, with its dense muscaroid-like inflorescence of lilac blue flowers, it is the admiration of all. Others which bloom in July are P. obliqua, with strong foliage and yellow flowers; P. sikkimensis and its purple Chinese allies, P. vittata and P. secundiflora.

The candelabra section are also useful to prolong the season of bloom in this genus, and the following are still blooming freely: P. Wilsoni, P. Poissoni and P. glycosma, all with purplish flowers, while P. helodoxa and P. Smithiana should be grown for their yellow heads of bloom. A good display of gentians is probable this year, judging by the luxurious vegetative growth. Such species as G. sino-ornata now covers yards of space, both in the rock garden and the rose garden. In the latter it is used as a ground cover under the taller roses. Here the earliest form to flower is Ward's No. 4859, which is much lighter in colour than that procured by earlier collectors.

G. Farreri is also growing well and will soon burst its flower buds. A pretty plant is G. Arethusæ, forming compact clumps of stems and foliage, with light blue and white coloured flowers, smaller in all their parts than G. sino-ornata. Whether this plant will be so amenable to cultivation as the latter has not yet been proved, but it certainly appears to be a good garden plant, both in regard to its habit and growth.



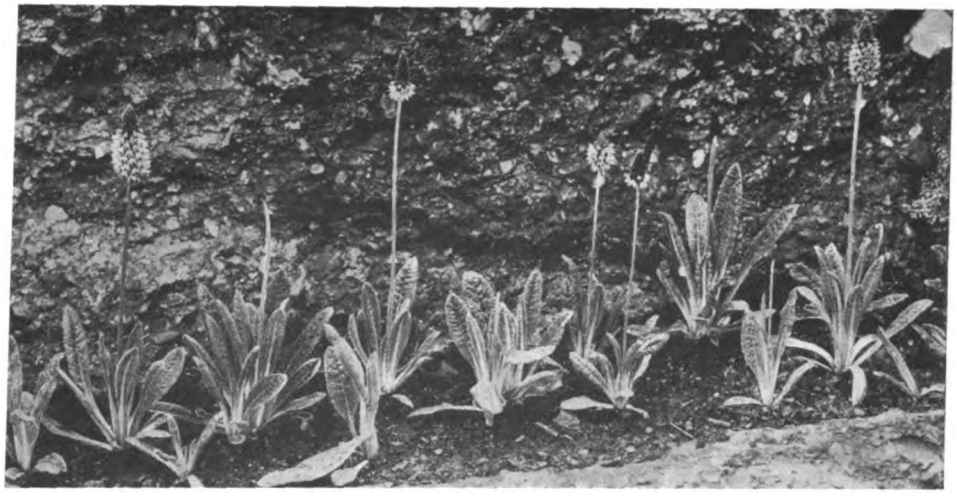
CLUMPS OF RHODODENDRONS ON THE HILL.

Flowers are also appearing on G. Lawrencei, the Siberian species, closely related to G. Farreri, though easily detected from that species by the longer, more slender stems, and narrower leaves, as well as by its smaller expanded flowers. Perhaps the darkest coloured flowered species is G. Veitchiorum, the corolla of which is of a deep purple blue. It does not spread so rapidly as some and does not seem common in gardens at present, but it is well worth a place where this genus is grown. A good patch of Dracocephalum bullatum may be seen covering about a yard of ground in a sunny, dry position, only 6ins. or thereabouts in height with numerous flowers of a pleasant blue. D. Forrestii and D. tangutica are good plants, either for the rock garden or border; both grow rather more than a foot high, and the former has attractive light blue flowers, while D. tangutica is of a much darker shade. Spenceria ramalana, a small rosaceous plant with nearly pinnate foliage and racemes of yellow flowers, makes a good show in July in a very dry position on a rising slope. To mention the many dianthus, campanulas, allium and other genera still at their best is impossible here, and the decorative effects should be seen to be really appreciated. In the wild garden, under the thin shade of pines and broad-leaved trees, Meconopsis

Digitized by Google

Wallichii and Lilium giganteum are grown in combination, and, flowering together as they do, form a handsome and attractive group. Large numbers of rhododendrons are planted in borders on each side of grass paths, and among them primulas and meconopsis enjoy their positions in the shade and moisture of the trees and bushes. Here, also, is to be seen Tricuspidaria lanceolata and Eucryphia pinnatifolia, opening well and in fine condition.

English iris, foxgloves, spiræa and Impatiens Roylei contribute to make this part of the garden a pleasant walk in summer, while numerous bulbs prolong the season in early spring. The herbaceous border is at its best in midsummer, and the bright sun of the last two months has done much to keep the long stretch attractive. By copious and successive waterings good foliage and a profusion of flower has resulted. Here the season has been favourable for the mulleins or verbascums, of which a number of species are grown, conspicuous among them being V. pulverulentum, V. longifolium, V. Wiedmannianum, and others, which provide a good show over a long period. Several of the Chinese senecios are admirable subjects for the border. Among them may be noted S. japonicus, with large brilliant flowers, reaching a height of 4ft; S. Veitchianus, S. fibrillosus and S. plantaginifolius, this last with crowded inflorescences and large individual flowers which stand out against the glossy and rather long, narrow foliage. It prefers a moist, rich soil. Among the many species and varieties of delphinium, the Abyssinian D. Welbeyi stands out as a late-flowering plant. The light blue flowers open about the end of July and continue until late summer. D. Cashmerianum and D. Brunonianum are still good. Adenophora Bulleyana forms a fine clump nearly 4ft. in height, with long branching stems bearing many light blue pendulous bells. Lereschia Flahaultii is a graceful umbelliferous plant with an airy appearance given by its light inflorescence above the dark foliage. Lobelia Tupa, sometimes thought to be tender, is represented by several clumps in full bloom. Aconitum volubile, and its variety latisectum have reached the tops of their supports. The white plumes of Stenanthium angustifolium, always an attractive plant when in flower, appears in mid-July and on until August. Under glass the different houses contain much of interest, both under cool and tropical conditions. The large central house and corridors are gay with wall and roof plants, among which may be noted Solanum Wendlandii with many magnificent trusses of light blue flowers; Mutisia decurrens, which here grows as well out of doors as under glass. Hidalgoa Wercklei, a scarlet climbing composite; Bomarea patacocensis, one of the finest of this beautiful climbing amaryllidaceous genus. Fuchsias in several species and hybrids adorn the roofs. Iochroma tubulosa, 20ft. in height, with many pendulous blue trumpet-like flowers, among its rather evil-smelling foliage. Bignonia Cherere, a strong grower, bearing numerous trusses of large red flowers, is an outstanding plant; while one of the prettiest plants in the beds is Cyrilla racemiflora, the leatherwood of North America, laden as it is with numerous racemes of small white flowers. A good representative collection of orchids may be seen in the houses devoted to their cultivation, where there are always some interesting and curious genera flowering. Many coloured foliage plants are grown in the stoves. Conspicuous among those flowering at present are Ouratea flava, a showy plant of the order Ochnaceæ, with large panicles of yellow flowers; Hibiscus Scottii, a yellow species from Socotra; Allamanda grandiflora, a less rampant grower than some of these showy plants. Ixoras in variety, and many others, help to give touches of colour. The occupants of the Aroid House, which are all planted in beds, grow luxuriantly and the foliage of Anthuriums, dracaenas, dieffenbachia and maranta, combined with the climbers from the roof make this house very popular.



ROBUST PLANTS OF PRIMULA LITTONIANA.

Visitors to the greenhouses should also take the opportunity of seeing the palm houses, the collection of rhododendrons under glass, as well as the houses devoted to insectivorous plants. In the garden are growing many of the newer introtions of trees and shrubs, and those specialising in outdoor gardening will find much of interest for all gardening purposes.

For the accommodation of those plants more recently brought to this country, long borders have been made where the specimens may be grown until they are removed to their final quarters in the collections on their attaining sufficient size. It is an astonishing fact how many of the recent Chinese introductions are thriving under the conditions that are met with in Edinburgh and the East of Scotland, and the results of the experiments in cultivation carried out here go far to show that the majority of these Chinese species can be planted with almost absolute safety in the majority of Scottish gardens, and so enhance their general appearance.

A CORNER OF THE FAMOUS ROCK GARDEN.

RASPBERRY TREATMENT

THE raspberry is a very popular fruit and is in great demand for preserving and other purposes. To get fruits to perfection they have to be grown well. It is not easy on an unsuitable soil to reach perfection, but granted a favourable soil, well prepared, there should be no difficulty in getting fine large fruits. Good cultivation, attention to details and growing the best varieties is essential to success.

A good open position should be chosen. A rich loam of fair depth and well manured is what the raspberry delights in. It is, of course, possible to grow them in any good garden soil which is not too stiff. Soils which are heavy and compact, and which bake in dry weather, require a lot of attention to prepare and to keep in condition for this fruit.

Well drained ground is essential. If possible the ground should be dug sufficiently early to allow time for it to settle for planting in October or early November. Good canes should be chosen for planting, and great care taken not to get the roots dry between the lifting and planting. The raspberry has a mass of fine fibrous roots which easily suffer if exposed to drying winds.

Raspberries are usually planted in rows, and occasionally in clumps. The distance varies according to whether it is desired to intercrop and depends somewhat on the soil. On poor soil it is well to give more space so that the canes can have the maximum amount of sun and air. Five to six feet between the rows is the usual distance and the canes set at 18ins. apart.

Eventually three to five canes should be aimed at for each stool. For very strong growers three would be sufficient.

PRUNING AND TRAINING.

After planting, the canes should be cut back to 2ft. from the ground, or to 9ins. according to circumstances. The latter is best except in severe winters when the cut back stem often dies some distance below the cut. Protection would, therefore, be necesasry, if cut to 9ins., in the way of litter. The canes left at 2ft. would be shortened back in spring, as soon as they show signs of growth. Generally the lower a cane is cut the better it breaks from the base.

If planted in clumps, it will only be necessary to place a strong stake to which to fasten the new growths as they develop. When planted in rows, the neatest way is to put a stout stake at each end of the row and strain two or three wires to support the canes. Four or five feet will be sufficiently high for the tops of the canes.

During the first year encouragement should be given to produce strong canes by keeping the ground free of weeds, mulching and, if necessary, watering.

On no account should the ground be deeply dug immediately surrounding raspberries, since it produces most of its roots near the surface and those are of a fibrous nature.

Providing the canes are vigorous, a good crop of fruit should be obtained the second year after planting. Early in spring a top-dressing should be given of good decayed manure, but not forked in.

Superfluous young growths should be pulled up to avoid crowding and to give extra light and air to the stronger young canes. Some varieties will need this more than others. The variety Lloyd George usually throws up too many growths, but Pyne's Royal is not likely to do so.

After fruiting the old canes should be cut right out. The new growths may require a little pruning in the way of shortening the strong growths, but the final pruning of the canes to the restricted height should be left till spring, owing to danger of frost, which might cause them to die back if cut early.

PESTS.

The raspberry is not subject to many serious pests. The beetle is no doubt the worst and is capable of doing a good deal of damage by eating the blossoms or cutting them off. The grubs destroy or infest the berries until mature, causing them to be unfit for table use.

As a means of prevention, old canes should be immediately cut out and burnt, as they harbour some of the pupæ. Fruits known to contain larvæ should be removed and burnt. Spraying with arsenate of lead when the blossom buds appear and again two weeks later. Jarring off the beetles on to tarred sheets on dull days when they are inactive. These measures would tend to keep the pest at bay, if not to eradicate it.

The stem caterpillars, also, do a certain amount of injury. The moths lay their eggs among the flowers, and the caterpillars feed upon the leaves. After hibernating in the ground, they ascend the plants in spring and bore into the young canes at a bud. This causes the shoots to droop. When this is noticed they should be cut off and burnt. Lightly pricking the surface soil and exposing the caterpillars to the birds will do good.

A disease known as "spot" occasionally damages the canes, causing them to die. Infected canes die instead of fruiting, and should therefore be cut away and burnt as soon as the symptoms —small red spots—are noticed. Bordeaux mixture at half strength is recommended as a preventative.

VARIETIES.

LLOYD GEORGE is a variety now well known and is termed a perpetual fruiter. It crops in summer and again in autumn on the tips and laterals of current growths. The fruits are large and bright red colour.

PYNE'S ROYAL.—This is a splendid variety, but must be well looked after to get good growths. It is a heavy cropper and the fruits are very large. An excellent sort for small gardens and large.

BAUMFORTH'S SEEDLING.—A good strain of this is an excellent variety. A good cropper, fruit large and dark crimson in colour.

THE DEVON promises to be a fine variety. It is a strong grower. Fruit conical in shape, large and good colour.

PROLIFIC is a good variety, with a good constitution, producing upright canes. A good cropper.

BOUNTIFUL is an excellent variety. Fruit large, and of good flavour.

SUPERLATIVE is still grown by many, but we have discarded it after a trial with most of the above mentioned varieties, with which it compared badly.

ARTHUR J. COBB.

GARDEN FRAMES

CONCEPTION of the true meaning of the term "well appointed garden" varies widely, and there are those who look upon frames and pits as being of small consequence; in fact, just makeshifts for those who, unfortunately, possess no greenhouses.

This is an error of judgment, for frames are not only a serviceable and necessary adjunct to a range of greenhouses, but for certain purposes either portable, unheated frames or brick-built heated pits accomplish better work than the larger and more elaborate structures. To begin to enumerate the special purposes of frames is a simple task, but it would be more difficult to choose the correct place to write finis to the list.

During the present season and well on through the winter cuttings of hardy perennials, florists' flowers, alpine and rock plants of varied character root better under a comparatively small, tight-fitting frame than in any other accommodation. An extensive range of choice shrubs need frames for the purpose of propagation, and seeds as well as cuttings will in numerous instances succeed better in frames than on greenhouse stages or shelves. Portability is of immense advantage, for one may place a frame behind a fence or wall, securing the benefit of protection from direct sunshine without the necessity for overhead shading, and when cuttings have rooted or seedlings have attained sturdy development the frame and its contents may be transferred to a sunny position.

SPRING USE OF FRAMES.

In spring frames are an absolute necessity for hardening the whole range of summer bedding plants, and many bulbous flowers that will not tolerate a forcing temperature may still be brought into bloom in advance of outdoor

Digitized by Google

stock with no other aid than the covering lights of frames.

Even the kitchen garden requires the aid of frames for raising seedling plants, and for the production of early salads, while a summer crop of cucumbers or melons can be grown to perfection in a frame mounted on a well built hot-bed.

Where conservatories have to be continually furnished with decorative plants, frames will be required for the summer accommodation of cyclamen, cinerarias, primulas, calceolarias, celosias and schizanthus, while the finest of liliums will spend much of their time in frames with advantage.

DESIGN AND CONSTRUCTION.

Design and construction is a matter of considerable importance, and in the case of portable frames only the strongest are good enough, for one cannot frequently remove a flimsy frame from place to place without damage. That is an important point, for there are frames on the market which are produced for cheapness and, being constructed of the commonest sappy timber, glazed with the thinnest foreign glass, the lights warp, cracking the glass, and the timber of the frame shrinks, admitting draughts, which do incalculable harm to plants, especially in their early stages of growth.

The double light portable frame illustrated shows a substantially built, roomy and easily handled frame made by the well known firm of Boulton and Paul, Limited, Norwich, who may be relied upon for expert workmanship and sound materials. This may be called a "general purposes" frame, but the firm also makes frames for special purposes, and it may be well to consider the relative merits of span-roof and three-quarter span-roof frames as well as lean-to patterns. For raising seedlings, rooting cuttings and for hardening bedding plants the ordinary lean-to frame is most appropriate, because it may be placed in any position or aspect required and the plants will all be near the glass, an important point, as all experienced cultivators know.

THE SPAN-ROOF FRAME.

The span-roof frame has particular advantages for production of flowering plants, the chief of which are admission of light from two directions instead of one, maintaining symmetry and balance in the plants instead of leaning toward a one-sided source of light, means of ventilating on both sides or on the leeward side in windy weather, and a depth sufficient for such pot plants as require a foot or so more than the customary depth of the lean-to frame. The centre of a good span-roof frame will accommodate fairly large fuchsias, azaleas and liliums, and when such a frame is required for Primula sinensis, cyclamen or other dwarf plants, a temporary series of shelves can be introduced to raise the plants nearer the glass.

A three-quarter span is convenient where space available is insufficient for a full span, the height being gained without extending the base beyond the width of an ordinary lean-to model.

VARIOUS FRAMES.

While the portable frame is of very great service for a variety of purposes, there are sometimes distinct advantages in having permanent frames with brick instead of wooden sides. Such frames if situated beside greenhouses may have a hot-water pipe run round them, and with no appreciable addition to the fuel bill the accommodation may be considerably increased for production of dwarf chrysanthemums, early daffodils, tulips and irises, dwarf pot roses, and a useful variety of other winter and spring subjects.

Brick-built, unheated frames are best for collections of choice alpines in pots and pans, and also for British ferns, collections of Chinese primulas, and the hardy terrestrial orchids.

Hot-bed frames have their special uses in raising early food crops, and where fresh stable manure is readily obtainable advantage should be taken of this useful means of obtaining a growing temperature. Naturally, hot-bed frames depend largely on the amount of out of season produce that is required, and probably for the small average garden this is the frame that is least necessary.

Messrs. W. Duncan Tucker and Sons, Limited, manufacture serviceable frames for large and small private gardens as well as for commercial establishments, and other good makers are Messrs. Foster and Pearson, Limited, and Messrs. W. Messenger and Sons, Limited.

The care of frames must, of course, include periodical painting with good paint, but both the lights and framework should be well scrubbed before being painted to remove slime and fungus. Equally important is the storage of frames when not in use. They should not lean in a manner that twists and warps the woodwork. They should rest evenly on planks or on bricks, and if on edge, should be secured against rough winds by a strong cord or wire.

A SUBSTANTIALLY BUILT DOUBLE FRAME.

CORRESPONDENCE

FLOWERS IN THE LOOKING-GLASS.

"To hold as 't were, the Mirror up to Nature."

SIR,—Has anyone ever noticed what an alluring background a looking-glass is to a floral arrangement? Shakespeare was before us in this, I feel sure I understand this line now! Picture to yourself a long, low mirror that rests on an old oak mantelshelf set eye level in the wall, a Buhl clock ticks melodiously in the centre, on either side priceless white china figures pose in graceful inimitable attitudes, beside them I place small bowls of flowers.

To-day the colour scheme is pink, white and yellow, and next to the curtseying china dame, who presumably is blushing behind her fan, I arrange a posy of fragrant mignonette from which stand up a few nodding heads of exquisite sweet peas; the wavy wings of the sweet peas in the glass and their equally beautiful faces before me. Flowers, let me remark *en passant*, stand an all-round view! They have no back hair to become dishevelled. From whichever point you regard them they are always beautiful, wonderful! And when the flower is a sweet pea you have a dream of beauty from any angle! Then in the other bowl beside the gallant who for ever bows and smiles towards his lady-love are a few choice roses. I watch them as I delicately turn them this way and that, like the Japanese expert endeavouring to bring them into their most graceful pose, and I assure you I *felt* that the flowers loved their reflecting background. I thought, but I won't vouch too positively for it, that I espied Mme. Abel de Chatenay nodding coquettishly at Son Altesse the Prince, and I almost heard the sweet peas in the opposite bowl titter! So I left them, to

Digitized by Google

try another looking-glass effect on the staircase.

In years long past some ancestress, troubled with more than her share of vanity, had conceived the delightful idea of a looking-glass wall which faced her as she descended the long flight of easy steps to the turn in the staircase from which one gets the first glimpse of a large black and white chessboard floor of the entrance hall. Behold her gowned in hoop and farthingale, powder and patches galore, daintily toying with her miniature fan and casting approving glances at herself as she trips lightly down! To-day she will find in the corner of her mirror a tall twisted glass vase, not of trumpet variety please, a wondrous thirsty contrivance to my mind, but a vase which I picked up on a foreign trip in the happy pre-war days, capable of holding more than a flower's ration of water. In it I have plunged a sheaf of white mallows somewhat shorn of their too ample green foliage, and among them, and with some trouble I own, I have enticed long trails of purple clematis to repose. (The colours of our erstwhile militant sisters, but no matter!)

So now if my lady ancestress comes down from her powdering chest to-day she will find mirrored before her two visions of floral beauty, to say nothing of her own lovely face above them, and I am sure she will approve of my latest efforts in "doing up the flowers," as we style it.—E. M. HARDY.

CISTUS RECOGNITUS.

SIR,—The name Cistus recognitus was given by Rouy et Fonc. in Fl. de France (1895), to a hybrid cistus occurring in Provence, Languedoc and the Eastern Pyrenees. Its parents are C. laurifolius and C. monspeliensis. The plant had previously been named C. glaucus in 1788 and it is included in their Prodromus fl. Hispanica (1880), by Willkomm and Large, under that name, and Willkomm figured it in his Icones in 1856 as C. Lèdon, Lamarck's name for the plant, given in 1790, transliterated by other authors into C. ledonius. C. glaucus is, therefore, the oldest name. Among the white flowered hybrids with the outer sepals smaller than the inner, it is distinguished by the *short* petiole and the many flowered inflorescence. C. Loretii is a hybrid between C. ladaniferus and C. monspeliensis, with the habit of the latter. It has one to five flowers in the inflorescence and they are spotted in some forms, unspotted in others. This hybrid was obtained by Bornet in Antibes but has been recorded as wild from Herault and Algeria. Its leaves are generally narrower than in Rouy and Foucaud's plant.—FRED. F. CHITTENDEN.

YELLOW HYACINTHS.

SIR,—In THE GARDEN of August 22nd I saw a letter from one of your correspondents, in which he states that there is not a true buttercup-yellow hyacinth. I expect he never has seen a double hyacinth, "Sunflower," which has the buttercup-yellow colour. Two single ones very near the buttercup-yellow colour are the new Hyacinth Prince Henry and the older variety, L'Or d'Australie.—A DUTCH BULB TRAVELLER.

RED-HOT POKERS.

SIR,—Reading "Clydesdale's" notes on Red-hot Pokers in your issue of August 22nd, and being most interested in them myself, I venture to send an account of my own experience and knowledge of newer varieties.

Two years ago I formed and devoted a long border for these beautiful and striking plants, and this year, in spite of the long, hot and dry period, I can see considerable progress in their growth.

The border faces south-east and is sheltered from the north by a thick shrubbery; it is composed of somewhat heavy but well drained soil, which all these lilaceous plants require. In exposed positions roots must be protected in the winter from heavy rains and severe frosts, but here, in Nottinghamshire, I have never had occasion to cover with ashes, although each spring I have protected early growth with small branches of fir or spruce, from late frosts.

Of the varieties I have planted, here are some: C. M. Pritchard is one that grows from 4ft. to 5ft. high, with stately spikes of yellow flowers; Grandis has immense heads of orange scarlet and is very gay; Rufus is a very effective one, with bright yellow flowers and a scarlet crown—it has proved rather slow-growing with me; others include Star of Baden, Royal Standard, with very bold spikes, Buttercup, John Benary, and Rouge et Soufre, which is especially fine growing from 5ft. to 6ft. high.

Of the gracilis variety, a group of dwarf hybrids, Lady Hillingdon is my favourite, having graceful spikes of sulphur yellow flowers with an orange tip; Sunset is another good one of this class, as also are Matador and Defiance.

Several new varieties have made their appearance since these were planted, so that I advise anyone who thinks of making a border to allow for fresh varieties when planting. They form a delightful stretch of colour and are in bloom from June to October. If any garden has the space and a suitable situation, I have no hesitation in recommending these lovely plants, which will amply repay for their trouble and attention by the brilliance of the many varied shades and heights.—E. BRANDRETH FREEKINGHAM, *Nottinghamshire.*

THE PROTECTION OF WILD FLOWERS.

SIR,—As a lover of the beautiful in nature, a life-long collector of plants for the herbarium and occasionally for botanic gardens, hon. secretary of the Watson Botanical Exchange Club (founded in 1884) and, incidentally, an Associate of the Society for the Promotion of Nature Reserves, I am much interested in your leading article on the protection of wild flowers in your issue of August 22.

I quite agree that "the actual urban dweller is unknowingly much more destructive" that the person who transplants a few roots of wild plants to his own or another garden; for the former frequently gathers huge bundles of flowers, some of which are strewn by the roadside, and others soon wither by the score when placed in dense masses in vases without sufficient light and air, without any cutting of the stems, and often with no renewal of the water.

I also believe far more good can be done in the schools by telling children of the harmfulness and selfishness of pulling up too many flowers (*e.g.*, bluebells, daffodils and primroses), however abundant they may be, and by occasionally asking owners or occupiers if notices requesting the public not to pick the flowers or take roots could be placed in certain places, than by the passing of by-laws by local authorities. You rightly say "the fault is caused [usually] by ignorance, not wilfully, and publicity is surely the obvious remedy." But when such vandalism is not the result of ignorance, as is sometimes the case, a by-law may do little good in these days of increasing and hated bureaucracy.

Rather than threaten, we must educate the people to reverence all beautiful things and to respect both vegetable and animal life more. The schools, the Kyrle Society, Boy Scouts and Girl Guides, field clubs and natural history societies can all help in this direction. Some of these have already done good work. Fortunately the intellectually and otherwise unfit teachers in elementary schools are gradually being weeded out, and their places are being taken (when funds allow) by better trained, less ignorant young men and women who have a higher moral and æsthetic sense to cope with these small matters, as well as the larger questions of honour and fair play, with which, indeed, they are closely related. Teachers and others can encourage the young to gather fewer flowers, to cut them with a knife or scissors and carry them home in a tin box of any suitable shape. They would thus not only keep fresh, but the mere fact of making a reasonable selection in the field would inspire a greater love of nature and instil into youthful minds more of the beauty and mystery of the plants themselves.

We must learn to trust the boys and girls from the slums more: to guide them rather than force or threaten them with fines or imprisonment for killing a rabbit or taking flowers which do not belong to them. In Bristol insufficient flowers or flowering shrubs are planted in the public parks, with two laudable exceptions. I have been told the excuse is fear that children will gather them. A decent and well constructed rockery is unknown in these parks, if we exclude the wonderful natural rockwork on the Downs (the Downs belong to the city), with their rare limestone plants, which botanists have visited for centuries. The flowery parks and public gardens of London and, let us say, Bath and, perhaps, Birmingham tend to show that flowers will not be much touched when the people become accustomed to love and admire them. Boys do not throw stones through the windows of a palace or an ordinary dwelling-house, but they may fling one at an already broken window of an ugly and dilapidated building.

As to the damage done by botanists to rare and often unattractive plants, I emphatically agree that it is often grossly exaggerated, and usually by persons of comparatively little experience of life actually in the country. In the London district it may be different. And with the increasing plague of motor vehicles the danger is more real. Even eminent botanists and others, whose work lies more in museums and laboratories than on the countryside, are sometimes joyfully surprised to be told how abundant many a rare plant is locally. The average town-bred botanist does not usually see a tenth of the plants in a locality which the trained field botanist with leisure would detect. Just as the experienced angler knows where to expect a trout to lie, so will experience and instinct help the real field botanist in spotting plants.

After nearly forty years' connection with one of the two botanical exchange clubs in England, I do not know of more than about two cases in which appreciable harm was done to a species by excessive gathering, and in both cases there is plenty of the plant left in several counties. The two British exchange clubs actually forbid the collecting of some of the rare orchids and various other rarities, and the collection of obscure and often less attractive species and varieties which only appeal to the botanist is encouraged.

If anything further be done *à propos* the top of Snowdon garden scheme, the chief drawback is the danger of upsetting the natural state of things by the dissemination of seed from such preserves, so that future students of plant distribution in the British Isles will have still harder problems to solve than we have to-day!—H. STUART THOMPSON.

PLEASE REMEMBER TO TELL OTHERS ABOUT YOUR PLANTS THROUGH THE COLUMNS OF "THE GARDEN."

GLADIOLI AND FRUIT AT VINCENT SQUARE

GLADIOLI were in the ascendant at the Royal Horticultural Hall, Westminster, on August 25th last. It was the occasion of the special Gladiolus Show, in addition to the customary fortnightly meeting, and besides the competitive exhibits, there were many large groups of splendid spikes.

Dutch growers were prominently represented and, while they staged very good spikes, it was gratifying to see that our home growers fully held their own and decidedly excelled with their novelties. Messrs. R. H. Bath, Messrs. Kelway and Son, Messrs. George Mair and Sons, and the Orpington Nurseries all had excellent collections. Chief among Messrs. Bath's varieties were Fire King, of vivid colouring; Black Pansy; Atherton, a deep primrose with a crimson blotch; and Electra, a brilliant scarlet with a crimson blotch. This collection also included many good primulinus hybrids.

A large group was also contributed by Messrs. Kelway and Son, who included Darkness, a smoky crimson-maroon; H. B. Stallard, rich pink, with a creamy centre; Mrs. Cely Trevilian, an immense blush pink spike; and King of Gladioli, among the large flowered sorts.

Although the Orpington Nurseries collection was rather smaller, it contained some excellent seedling gladioli and named varieties. Odin is a large salmon-pink, with a vivid crimson-lake blotch. Marshal Foch, large lilac with rose-pink lines at the base of the flower; and Red Emperor, were splendid.

The Continental exhibitors were Messrs. K. Velthuys and Co., Messrs. Konijnenberg and Mark, Messrs. J. J. Grullemans and Sons, and Messrs. Stouterbeck van Til, Limited. Their outstanding varieties were Mr. Mark; violet shades; Veilchenblau, blue-violet; Proserpine, vivid rose; Ophelia, apple blossom tints; Magnolia, large white with a few carmine lines at the base; Autumn Queen, white with crimson feathering; and Louise, lilac shadings.

The Foremarke Cup, which is offered for the best collection of twenty spikes of Gladioli, in not fewer than ten varieties, was awarded to Messrs. George Mair and Son, the only exhibitor, for a superb collection, which included Queen Mary, large white; Duchess of York, beautiful rose shades with white centre; Jean Mair, vivid carmine with white blotch at bands; Peach Blossom, of peach-pink colouring; and Kyle, a fine deep rosy-lilac.

Dahlias were shown in very good quality by Messrs. Carter Page and Co., Mr. J. West, Messrs. J. Cheal and Sons and Messrs. J. Stredwick and Sons, while Messrs. Chaplin Bros. and the Rev. J. H. Pemberton, showed good collections of roses. Their customary greenhouse carnations were staged by Mr. C. Engelmann and Messrs. Allwood Bros., and Messrs. Stuart Low and Co.

Some beautiful sprays of Eucryphia cordifolia, Solanum jasminoides and Berberis corallina were included in his interesting collection by Mr. G. Reuthe, who also showed various border and bog plants.

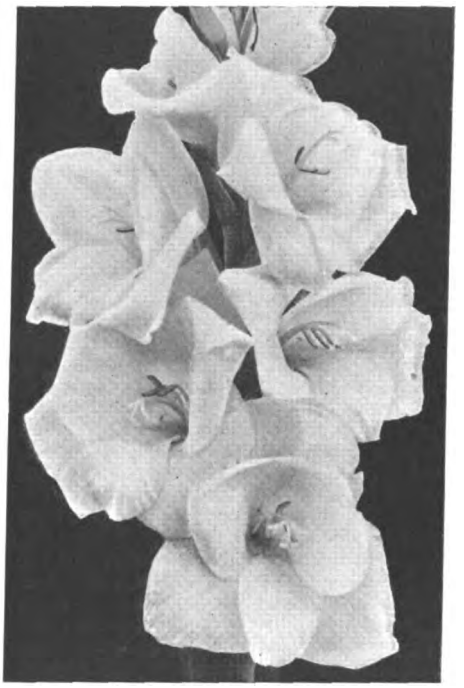
The tall-growing lobelias, chiefly varieties L. cardinalis, were well staged by Messrs. B. Ladhams, Limited, who showed the pink flowered Mrs. Humbert, Purple Emperor and vivid spikes of the Crimson Magnificent. As shown by Mr. F. G. Wood, Physostegia (Dracocephalum) virginiana is still a useful border plant for late summer blooming, and he also had graceful branches of the Tamarix and some good heleniums.

A collection of fruit trees in pots was of such high quality that the committee awarded a gold medal to Mr. J. C. Allgrove. In front of the trees there were baskets of gathered fruits of various kinds of superb quality. The chief apples were Keswick Codling, Red Victoria, Lady Sudeley and Red Astrackan, while the peaches, nectarines and plums were equally meritorious.

A collection of gathered fruits set up by Mr. H. Hemsley included very good baskets of apples Lady Sudeley, Beauty of Bath, Worcester Pearmain, Stirling Castle and Gloria Mundi. Nectarine Lord Napier and Peach Royal George were of very tempting appearance.

The only exhibit of plums for the Bunyard Medal was by Mr. R. Staward, Ware Park Gardens, and he was awarded the medal for a praiseworthy collection of such sorts as Monarch, Late Orange, Black Diamond, Primate and Green Gage. With their carnations Stuart Low and Co. showed good fruiting figs in pots.

Only a few alpine plants were exhibited, but those few showed how interesting the rock garden can be in late summer, when



GLADIOLUS WHITE LADY?

the majority of mountain plants have finished their short season and set their seed.

Messrs. Prichard and Son showed Anemone Hupehensis from Western China, the lately found parent of A. japonica. A neat little plant with shell-like flowers of deep, purplish pink carried on 10in. stems, with all the grace and refinement of a true species. Codonopsis Meleagris, a sinister flower in greenish white, veined with dingy purple, with an appropriate smell. Fuchsia pumila, a tiny compact bush with plenty of cardinal red flowers. Polygonum vaccinifolium, one of the best of the dwarf knotweeds, making a wiry, but not invasive mat, carrying tight spires of soft pink flowers.

Messrs. Reuthe showed Leucojum autumnale, a very autumnal flower in the ghostly pallor of its thin bells against the dark mahogany-red stems. Parnassia Caroliniana, a magnified grass of Parnassus, formal and elegant, in contrast with Silene Schafta, which is rather coarse and exuberant for an alpine.

NEW AND RARE PLANTS.

GLADIOLUS WHITE LADY (?).—As this name has already been applied to a gladiolus, the variety must be renamed. It is a magnificent spike of large pure white flowers, which have a touch of pale primrose in their centres, and the same colour lightly flushes the unopened flower buds. Award of merit. Shown by Messrs. Kelway and Son.

PHLOX ANNIE LAURIE.—This is a useful herbaceous variety of sturdy habit and producing big trusses of salmon-pink flowers which have a narrow rosy zone. Award of merit. Shown by the Hon. Vicary Gibbs.

PHYSOSTEGIA VIRGINIANA ROSEA LADHAM'S VARIETY.—A vigorous form of this useful border plant which was introduced from North America in 1683. It is a variable species and has given rise to many varieties of which this latest is decidedly the best. The plant is larger in all its parts and the flowers are a pretty pink colour. Award of merit. Shown by Messrs. B. Ladhams, Limited.

NEW DAHLIAS.

The following new varieties were selected by the Joint Committee for trial at Wisley next year.

CHEAL'S PINK.—A small decorative variety of good form and bright pink colour. The centre unopened florets are shaded dull heliotrope. Shown by Messrs. J. Cheal and Sons.

CINTRA.—A very useful yellow miniature peony dahlia of value for bedding purposes. This and the two following were shown by Mr. A. J. Cobb.

MRS. JOHN CROSSLING.—An attractive, rounded miniature peony of dwarf habit. The foliage is purplish and the flowers are of buff apricot shading.

ST. ANDREWS.—A vivid scarlet crimson dwarf miniature peony, which has dark stems and foliage.

EVELYN HANCOCK.—A large decorative bloom of broad cactus-like habit and lemon-yellow colour. This and the following were shown by Messrs. J. Stredwick and Son.

HARRY STRUTT.—A good brick-red cactus of the best exhibition type.

HENRY B. MAY.—A salmon-pink decorative variety of large size and tipped with white.

J. EMBERSON.—A large salmon-pink cactus variety with a primrose centre.

MARY MURRAY.—A pale orange cactus dahlia.

NOBILITY.—A wine red cactus dahlia tinged with purple.

ROTATION.—A good white cactus variety.

SHEIK.—A large decorative of pale primrose colour which is deeper in the centre of the blooms.

STEDFAST.—A large mauve-flushed decorative variety.

ORCHIDS.

BRASSO-LÆLIO-CATTLEYA GOLDEN GLORY (B.-c. Mrs. J. Leemann × L.-c. Orion).—This well cultivated plant bore a couple of large flowers, the sepals and petals clear lemon yellow, the finely formed labellum crisped and fringed at the margin, of bright rose colour on the outer zone, the central area yellowish with crimson suffusion. A marked improvement on the well known Brasso-Cattleya Mrs. J. Leemann. Shown by Mr. C. J. Lucas, Warnham Court, Horsham. Award of merit.

ODONTOGLOSSOM LAURENTIA MAGNIFICUM (Jasper × Olympia).—A showy hybrid and remarkable for flowering so well at this season of the year. The arching spike carried ten flowers of thick texture, the sepals and petals tinged with rose and bearing reddish markings. The large labellum broadest at the apex, white, with a bright red blotch on the central area, and a conspicuous crest of yellow colour Shown by Mr. J. J. Bolton, Claygate, Surrey. Award of merit.

THE GREAT FLORAL SHOW AT SOUTHPORT

AUGUST 26th, 27th and 28th last found Southport as the Mecca of all gardening enthusiasts, who had come from near and far to view the truly magnificent show arranged under the auspices of this enterprising county borough. It was probably the finest horticultural exhibition outside of London, both from the point of view of the extent of the show, which covered close on two acres, and the high quality and standard of the exhibits. It is a notable achievement by a borough to which flower shows are a new venture, and that they have made a permanent success of it is beyond question. The arrangements could not have been better.

The majority of the large trade exhibits were in the non-competitive classes, and they probably attracted the greatest attention, as they most certainly deserved. Gladioli were present on almost every stand where hardy flowers were shown, while in addition there were several solo exhibits. Mr. W. J. Unwin had a tastefully arranged stand of his primulinus hybrids all in remarkably good condition. The award of a large gold medal by the Borough of Southport and a gold medal by the Royal Horticultural Society was really deserved by this stand. Messrs. Bath, Limited, of Wisbech, also had a pleasant and light arrangement in which the individual form of the flowers could be readily appreciated. Fine spikes of primulinus hybrids, notable among which was the variety Lydia, were staged by Messrs. Lowe and Gibson. In addition to these, Messrs. Bees, Messrs. Wilson and Agar, Messrs. Edwards and Messrs. Artindale staged excellent groups of large-flowered gladioli, all the flowers being of exceedingly fine form and size. In Messrs. Sutton and Sons' floral group, numerous tastefully arranged baskets of large-flowered gladioli were set out, and these stood out in great contrast to the baskets of brilliantly coloured seedling dahlias and the deep yellow marigolds. The dahlias were of especial interest, having been sown in the early spring of this year and transplanted in June. Messrs. Carter's arranged a rather novel exhibit in the form of a square lay-out. Lilium Henryi and L. speciosum rubrum formed the centre part, with a surround of gaily coloured mixed asters.

The exhibit of Mr. H. J. Jones once again attracted considerable attention. With a foreground of all his famous phlox varieties in baskets, against a background of large-flowered gladioli in all shades. Phloxes were also staged by Messrs. Bakers of Wolverhampton. These were interspersed by double hollyhocks, whose tall and elegant flowering stems greatly assisted to relieve the stand. One of the most outstanding exhibits was that of the Hon. Vicary Gibbs, staged and arranged under the able guidance of Mr. Edwin Beckett. This fine exhibit was awarded the silver challenge trophy, value £75, presented by the proprietors of the *People* for the most meritorious non-competitive exhibit in the Show. Messrs. McBean were successful in winning the silver challenge trophy presented by Sir John Brunner, Bt., for the most meritorious competitive exhibit in the Show. Their stand of orchids attracted considerable attention.

Carnations were displayed by Messrs. Allwood Brothers and Messrs. C. Engelmann. Both firms staged a very fine collection, consisting of many hundreds of blooms in good condition. Carnation Red Laddie, whose popularity bids fair to outdo its close colour relatives, gained an award of merit. Fruit was in the capable hands of Messrs. George Bunyard, Messrs. T. Rivers and Mr. Edward Parsons. The apples especially were of good colour, while the skin was pure and clean. The foliage of all the trees which were in pots was good. Mr. Edward Parsons showed his new Worcester Berry, a cross between Boskoop Black Currant and Whenham's Industry Gooseberry. The berries are of a good size and form, and the bushes appear heavy croppers. Sweet peas and roses were well staged by Messrs. Dickson of Belfast. Some of the well known varieties of roses were shown in spray vases and baskets, and formed a pleasant background to the more delicately coloured sweet peas, the tones of which were greatly enhanced by the dark foliage of the roses. A very fine group of ornamental foliage plants was that staged by Messrs. John Peed and Son. The green of the foliage was relieved to some extent by the introduction of clumps of lilies and hydrangeas, with a foreground of gloxinias. In contrast to the warm tones if the gloxinias, one found the fine collection of perennial scabious in all shades of blue, staged by Messrs. Isaac House. The blooms were all excellent, and fully deserved the award which was given.

A very fine collection of dahlias and chrysanthemums was that arranged by Mr. H. Woolman of Shirley. The colour and size of the blooms were remarkable. Many firms were exhibiting hardy herbaceous flowers, which included phloxes, rudbeckias, heleniums, sidalcias, and many other representatives of the hardy border. A striking stand was that of Messrs. Blackmore and Langdon, whose groups of double begonias and towering spikes of delphiniums in all shades of blue and mauve were much admired. Mr. Thomas Carlile and Messrs. Hewitt of Birmingham also staged fine collections of well grown varieties of this excellent blue representative in the border. The latter firm also staged a very fine collection of dahlias, embracing the majority of the types. The cactus-flowered varieties were in the best condition, the individual blooms being 6–8ins. across and brilliantly coloured. Hollyhocks were to the fore in the collection of Messrs. James Vert and Sons. All the varieties were double, and such as Crimson Queen, Salmon Queen and Fire King were indeed handsome. In roses Messrs. McGredy of Portadown were successful with a very fine collection, in which all the well known varieties and a few of their novelties, such as Gwyneth Jones, were represented. Messrs. Bees of Chester also had a tastefully arranged group in which many of the same varieties were shown. In addition to a very fine collection of dahlias and sweet peas and potatoes, Messrs. Dobbie and Co. of Edinburgh staged some fine roses. A few firms took full advantage of the space at their disposal and staged vegetables along with flowers. Messrs. Webbs, Toogoods, Dickson and Robinson, and Daniels of Norwich, all followed this arrangement, and it was successful. Gladioli in the majority of cases were employed as a background to lend a touch of brighter colour to the more dwarf subjects in the foreground.

Messrs. L. R. Russell stood alone with their fine exhibit of clematis in pots. The notable variety was Crimson King, of good vivid colour and of excellent habit and character. Water lilies were represented in the arrangement of Mr. Amos Perry. Probably too much was attempted in the space at his disposal, but nevertheless the general effect was good. Clumps of tritomas, Liatus and veronicas lent patches of colour round the small pond which the lilies occupied. There was also a fine exhibit of violas by Mr. Jones of Salop, and his collection included many excellent sorts.

Laid out in the grounds were the rock and water gardens, and these were of a high standard. In all the central theme was a trickling stream with two or three small pools in its course. In Messrs. T. Hayes' garden, which gained the silver challenge trophy presented by the Borough of Southport, the design, proportion and shape of the garden left nothing to be desired. The rocks of Westmorland limestone were worn and moss-covered and were laid out in pleasant lines. The quiet natural setting was greatly appreciated, and this, together with the selection of suitable choice alpines as inmates and the colour schemes, gained for them the premier award. One notable plant in their exhibit was a charming white form of Erica kevernensis.

In the competitive and amateurs classes the entries were numerous and the competition very keen, thus leading to a very high standard. In the many classes, of which there were 260, great improvements in the general display and arrangement could be noted. The decorative classes were well patronised, and the beauty of the arrangements and the effects which were attained were unquestionably among the best we have seen.

In the fruit classes, those devoted to grapes were really outstanding. There was little to choose between the different exhibits. The varieties shown were chiefly Muscat of Alexandria and Black Hamburgh. One large tent was given over solely to competitive exhibits of vegetables, and the majority of the collections reflected great credit on the growers. In another tent was housed floral decorations for the dinner-table and exhibits of violas and pansies, which were also of an exceedingly high standard. The Clay Perpetual Challenge Trophy was accorded to Mr. H. J. Milner of Handsworth for his collection, which was most tastefully arranged.

That the amateur exhibitor has assumed an important place at horticultural exhibitions is beyond doubt, if one can judge by the display at Southport. Numerous exhibits of all the necessary adjuncts to a garden and gardening knowledge found a place in the grounds, and these were, indeed, worthy of the attention which was given to them.

LISTS OF AWARDS.

Large Gold Medals.—Messrs. Allwoods for carnations; the Hon. Vicary Gibbs (gardener, Mr. E. Beckett) for vegetables—also awarded the *Gardeners' Chronicle* Medal; Messrs. Dickson and Robinson, flowers and vegetables; Messrs. Dobbie and Co., Limited, roses, dahlias and sweet peas; Messrs. Isaac House and Son, new perennial scabious; Messrs. T. R. Hayes and Sons, heath garden; Mr. H. J. Jones, gladioli and phloxes; Messrs. John Peed and Son, greenhouse flowering and foliage plants; Messrs. Thomas Rivers and Son, Limited, fruit trees in pots; Messrs. Sutton and Sons, seedling dahlias and gladioli; Mr. W. J. Unwin, gladioli.

Gold Medals.—Messrs. Blackmore and Langdon, begonias and delphiniums; Messrs. George Bunyard and Co., fruit trees in pots; Messrs. James Carter and Co., asters, lilies, gloxinias; Messrs. Daniels Brothers, gladioli and other flowers; Mr. Amos Perry, a lily pool; Mr. H. Thirkeldsen, formal garden; Messrs. Toogood and Son, cut flowers and vegetables; Messrs. James Vert and Sons, double hollyhocks; Messrs. E. Webb and Sons, flowers and vegetables; Messrs. Wilson and Agar, cut gladioli.

In addition to the above, there were many awards of silver and silver-gilt medals. The deputation of the Royal Horticultural Society made the following awards:

Gold Medals.—The Hon. Vicary Gibbs, vegetables; Messrs. S. McGredy and Son, roses; Mr. W. J. Unwin, gladioli; Messrs. A. Dickson and Sons, roses and sweet peas; Mr. James Cypher, decorative group; Mr. H. Woolman, dahlias; Messrs. M. Prichard and Sons, herbaceous flowers; Messrs. T. Hayes and Son, rock garden.

APPLES AND PEARS IN MIDLOTHIAN.

TWO young trees of Apple Cox's Orange Pippin in 10in. pots, flowered well early in April, and for a neighbour they had a small tree in a 7in. pot of Apple Lamb Abbey Pearmain; this tree had only a very few flowers—of delicate pink and white colour. The flowers of all the three trees were brushed over several times with the rabbit's tail to secure cross pollination. The results have been successful, and we are rewarded with good crops on each tree, Lamb Abbey Pearmain having larger fruits than Cox's. It is said that Cox's Orange Pippin is self sterile, but there is no record so far as I am aware of Lamb Abbey Pearmain ever having been used as an affinity. The flowers of Cox's under glass are a delicate shade of salmon pink just before they open out. It is stated in McIntosh's "Practical Gardener," a book published more than eighty years ago, that Lamb Abbey Pearmain originated in this country from a seed of Newton Pippin.

Beurre d'Amanlis is stated to be self-sterile, but we secured a few very large fruits early in August of this year, from a pot tree, which flowered profusely under glass throughout the latter part of March. Certainly the rabbit's tail was freely used among the flowers, but only transferring the plants own pollen from flower to flower. Two years ago a better crop was got from this tree, and this, no doubt, was owing to Pear Marie Louise d'Uccle being a near neighbour and in flower at the same time. Each of these varieties is capable of fertilising the other, as when each is flowered separately or kept separately, little or no fruit is produced by either.

Marie Louise d'Uccle was smothered with flowers and flower buds in March, 1921, yet not one fruit was obtained from the tree. I even hand-pollinated the flower, yet the tiny fruit fell off later.

ROSES IN SCOTLAND.

FOR three weeks in July the hybrid tea roses made a wonderful display; the fine sunny weather which we had throughout that month suited the roses and each variety gave of its best. In the first half of August the rose display was flat; but now on the young strong stems—some of them about 3ft. high—numerous flower buds are formed. The growths have arisen on older parts of the plant stems from near the ground level, and a noteworthy point about them is their deep, brownish-red colour, which is coated in a fine healthy bloom. The young leaves, too, match these stems, and remind one very much of the foliage colour of Prunus Pissardi. Lady Alice Stanley, Richmond and Miss C. E. Van Rossem exhibit this colouring, La France just a little, while Old Gold is the best coloured of all; this semi-double rose is very floriferous and suited for a wet or dry year. By the appearance of the plants now a second splendid display of blossoms will be borne by them about the end of August. Roses of all kinds have flowered profusely, while those of the Wichuraiana type have blossomed beautifully overhead, blending in tone of colour with the border flowers which give a display in the late summer. Even those raised from cuttings a few years ago have flowered well and grown so thickly that the ground is hidden by their healthy stems and foliage.

ANNUALS FOR SOUTHERN GARDENS.

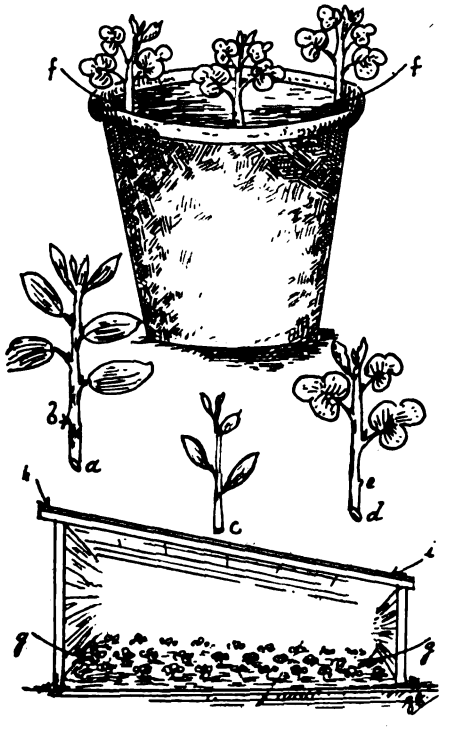
THE sowing of annuals in the spring is such an established fact that few give any attention to sowing seeds during the present month. That autumn-sown plants give fine results is beyond question, and, moreover, they flower earlier than spring sown, and fill up a dull period after many of the tulips, etc., are past their best. Many annuals sown in the autumn are far better than those sown in March or April, an illustration being self-sown eschscholtzias. Here and there a plant springs up, and the robust specimen, with its wealth of bloom in early summer, points not only to the value of the time to sow, but also the necessity of ample space in which to develop. Other instances could be quoted. Thin sowing should be the golden rule, and later on the seedlings must be reduced, bearing in mind the space the plant will require when fully grown. The "thinnings" can be transplanted to other parts of the garden if needed, and if the seed is sown where the plants are intended to flower, lines or rows will be preferable to broadcast sowing, because they can be more easily cleared of weeds which make progress during a mild autumn and winter.

A light, well-drained, rich soil is best for autumn-sown annuals, but a heavy rooting medium can be improved by the addition of old mortar rubble, leaf-mould, and ashes from the rubbish fire.

Slugs will be the greatest enemy during the winter months, when growth is slow or stationary, but these can be trapped by various methods, and an occasional sprinkling of old soot and lime will help to keep these marauders in check. Among annuals suitable are the eschscholtzias, of which there are some striking varieties; the Shirley poppy is an ideal subject, also godetia, larkspur, clarkia, cornflower, coreopsis, nemophila, silene and many others. Sweet peas will be sown some weeks hence.

CUTTINGS OF SOME BEDDING-OUT PLANTS.

THE amateur who does not possess a lot of glass, in the form of greenhouses or frames, should get as many cuttings inserted, rooted or, at least, callussed as soon as possible after mid-August. Usually,



it is the cuttings that do not form a callus before the dark days of winter come that fail to pass through that trying time safely. It is not always frost that causes the losses, but excessive damp, both natural and that caused by injudicious applications of water. Cuttings of zonal pelargoniums and fuchsias should be dealt with first and be inserted in a sandy loam, more leaf-soil being mixed with the loam for the benefit of the fuchsias, also for lobelia, verbenas, coleus, ageratums, heliotrope, etc., than for the zonals. Cuttings of the latter should be prepared one day and inserted the day following, being kept in a cool place in any shed or cellar in the meantime. The cuttings of all other kinds should be inserted as soon as they are prepared. Water all, immediately, to settle the soil around the stems. Place all in a cold frame, admitting more air to the zonal than to any of the other kinds. Some old plants of lobelia may be topped now with a view to lifting and potting in September. Sever the stems of the cuttings as shown at *a*; remove lower leaves, *b*; *c*, tiny cuttings; *d*, stem cut off; *e*, lower leaf, also. Insert the cuttings as shown at *f*, *f*. Later, take cuttings of calceolarias and marguerites and insert in a sandy bed in a cold frame as shown at *g*, *g*, ventilating a month hence at *h* or *i*, according to the direction the wind blows.

HARVESTING AND STORING POTATOES.

THERE should not be any lack of effort, this year, made to lift and store potato tubers in first-rate condition and in the best way possible to secure freedom from rotting during the winter months. Crops are, in many districts, below average, and the quality is not good in many cases; there are, too, lots of tubers irregular, and numbers are "grown out" owing to the arresting of their growth by the spell of hot weather and the recent dull, wet month. Instead of storing all the tubers in one big heap, whether under sheds and outbuildings or in potato clamps, form at least two heaps, one composed of the surplus early varieties and the whole of the mid-season ones, and one heap of the main-crop tubers. Where seed tubers are wintered at home it does not matter if they are exposed to the sun for several days, but not to rain. In the case of eating tubers it is quite different; one hour's exposure on a sunny day is quite sufficient. I never have seen tubers, when lifted and exposed to the air, turn green so quickly as they have this year. Eating tubers should not be exposed to rain; if wetted and stored they decay, and it is difficult to get them sufficiently dry again without using an open shed. Against all outside walls a thick layer of straw should be placed to guard against frosts; and, where stored in sheds with wooden floors, the tubers should have a thick layer under them, too. Outside clamps should be formed on a dry base, and the straw to be used must be kept dry in a shed.

PREPARING GROUND FOR FRUIT TREES.

THE wise cultivator will begin the work of preparing the soil for his fruit trees at an early date. Planting is, or should be, done in November, but the soil requires treatment long before that date. Fruit trees may be regarded as permanent occupants, and, once planted, they cannot be disturbed at will, like annual crops, in order to clean or improve the lower layers of soil. All this kind of work should be done very thoroughly before the trees are planted. First decide about the site, and, if wind protection must be provided, decide now as to its form and, if trees are to be used, plant them at a suitable distance so that neither their roots nor branches will interfere with the fruit trees in any way. Cupressus macrocarpa may be planted 50ft. or even 30ft. away on the south-west side, as they will bear cutting

Digitized by Google

well, especially if this work be done three times a year, so that only young wood is removed each time. If the fruit quarters are to be extensive, and the site is an exposed one, then plant Pinus insignis about 100ft. away to the south-west. It does not matter whether the soil be sandy, medium, clayey or stony, it should be deeply trenched as soon as possible, and all weeds and foreign matter removed, but not the stones. The turf portion may be taken off, to be returned in due course in the form of a surface dressing, or it may be buried; in the latter case it should be covered about 16ins. deep. Light and gravelly soils do not need draining, but clayey ones do; and where plums, cherries, etc., are to be planted, lime should be freely added, soon, to the surface soil.

LIFTING AND PLANTING EVERGREEN SHRUBS.

WHERE evergreen shrubs are to be lifted and replanted this autumn the preparatory work should be attended to in good time, so that the subjects may be lifted and replanted quickly, not exposing the roots longer to the air than is absolutely necessary. Variegated box, gold and silver hollies, Ilex aquifolium sorts, gold and silver euonymus, elasaganus varieties, lavender, Lavendula spica, tree purslane, cupressus, conifers as shrubs, and ivies, also treated as shrubs, Choisya ternata, escallonia macrantha (both requiring sheltered positions), Kalmia latifolia, Olearia Haastii, veronicas, rhododendrons, laurustinus, arbutus, Garrya elliptica, osmanthus, pernettyas, Cotoneaster microphylla and evergreen oaks. These are the principal evergreens grown in the common garden and regarded as necessary in these days. In the first place, the holes should be made in readiness for the shrubs, not mere holes formed in a hard soil and just large enough to contain the roots, but wide and deep enough to contain them and plenty of fresh soil as well. If the soil is very dry, thoroughly saturate it in and around each hole, also the soil round the roots of the shrubs before the latter are lifted. Do this the day before the work of lifting is done; take pains with the work, do it well, removing as much soil as possible with the roots, and make the soil firm round them. The stems of choice specimens should be wrapped in wet cloths and moistened daily afterwards for one month.—G. G.

CRINUM POWELLII, A FINE HYBRID.

CRINUM POWELLII.

DURING the month of August a delightful feature of the herbaceous borders at Castleford, Chepstow, was two fine clumps of C. Powellii and C. Palbum; an illustration of the former appears in this issue of THE GARDEN.

C. Powellii is of hybrid origin, the parents being C. Moorei and C. longifolium. The flowers of the type are reddish-rose in colour, of fine texture and the spikes stand well above the foliage.

When established flower scapes are produced freely, and this beautiful crinum should be planted more freely in borders, as it is quite hardy in the South of England, in fact, it is not so tender as some would have us believe. A start should be made with good sized bulbs, and fairly deep planting is recommended during the spring months or even the end of May. They delight in a rich soil, and will pay for an annual mulching of partly decayed manure.

Our plants have been in their present position for twelve years, and have never had the slightest protection, but in colder districts it would be advisable to select a sheltered spot, where it is well drained, and to cover the neck of the bulbs with hay bands during a period of frosty weather.—T. W. B.

GALTONIAS.

AMONG plants that have suffered owing to the drought, must be included galtonias (Hyacinthus candicans), which, as a consequence, are not so tall. One exception may be noted in the case of bulbs which were left in the ground last winter, and therefore had a good start over bulbs planted in March. Am I correct in assuming that galtonias are less met with than they used to be, and that one reason is because, in a general way, bulbs decay if left in the ground the year round? Only in well drained, sandy soil is it safe to do so, and, even then, failure sometimes follows.—CLAREMONT.

ROOTING CUTTINGS.

WHEN rooting cuttings, especially those from hard-wooded plants, it is often a difficult matter to keep the soil in the proper condition as regards moisture. I have found the following plan to give excellent results: Two pots are secured, one of which is somewhat smaller than the other. In the bottom of the larger pot a good layer of broken crocks is arranged to secure free drainage. Now take the small pot and close the hole in this with a cork. Stand the little pot inside the big one right in the centre, so that its base rests on the layer of broken crocks. The space between the two pots is packed with a light sandy soil suitable for a rooting medium for the cuttings. In this soil the cuttings are inserted all round the band of soil which surrounds the little pot. Then, to complete, fill the small pot to about half its capacity with water. The porous nature of the pot allows the water to soak through very slowly. This is just sufficient to keep the soil in which the cuttings have been placed in an ideal condition, and it will never be too dry or too moist. Many cuttings which have proved most difficult to root by ordinary means do well when this simple plan is followed.—S. LEONARD BASTIN.

A DAY ON THE MONZONI.

THE Monzoni Valley in the Dolomites tucks itself just round a corner away from the main flood of August visitors. From Bolzano you take the motor up a dithery road to Carezza, with its palatial hotel and Liliputian green lake—such a little lake to lend its fame to so great a palace. Beloved Bozen and the Karer See do not yet recognise themselves in these new Italian names for most un-Italian places. Thence you descend to Vigo in the Fassa Valley, and there you part company with the throng of tourists and go up the sequestered Val San Nicolo, shrouded in pine woods. At a small chapel you turn to the right and cross rocky meadows till you see the Taramelli Hut perched ahead on a hillock of its own.

Thus far, directions are easy, with towns and roads and lakes and what not, with proper names, to help; but after the Taramelli Hut you follow the flowers. Linaria alpina holds your interest up the first stiff climb; Geum reptans and Ranunculus glacialis in peculiarly rosy form bring you to an admiring standstill at the foot of an enormous scree of red rocks, in every interstice of which they luxuriate; the Rhœtian poppy, Potentilla nitida and edelweiss draw your steps over a miniature pass; Ranunculus Seguieri encourages you along the edge of a white limestone *débris* slope to Thlaspi rotundifolium in a wilderness of rocks just beyond; you peer down upon Ranunculus parnassifolius growing in white silt that drops steeply down to a mountain tarn; you meander with the Primula glutinosa and P. minima and their puzzling hybrids across a hummocky moor; and on the pass itself are Eritrichium nanum, Myosotis rupicola, Androsace alpina, and Anemone baldensis.

The ascent from the Taramelli Hut to the pass takes you barely more than an hour: where else in all the Alps could one hope to walk straight up to sixteen first-rank high alpines, at the rate of one every four minutes? In 1924 the top of the pass was a desolation but for the flowers. The splinters of rock shattered by gunfire had added to the geological topsy-turvydom which attracted Humboldt and many another scientist to the Monzoni. The natural amphitheatre just below the pass on the near side was a circle of empty barracks 8,000ft. high, carved out of the hillsides, like a Roman arena surrounded by the stalls of the audience. On the far side were acres of barbed-wire entanglements (of rustless wire that was as new after even so many years), beneath which I crawled from one rounded cushion to another of Ranunculus Seguieri. Memory resurrects a picture of broken-down trenches and Ranunculus glacialis; of dug-outs and Primula glutinosa; skeletons of mules and Androsace alpina. I spent an arduous slippery hour swarming up the rocks on the right of the pass, which are here as smooth as the glacis of one of Vauban's forts, attempting to photograph the crannies full of Eritrichium and androsace (white as always in the Dolomites, not pink as elsewhere). My wife meanwhile sat below on the moss-grown roof of a dug-out, eating lunch, and, when at last I descended, pointed with "poor fool" look to the eritrichium thick on the level at her feet. But was it eritrichium? On hands and knees I peered at one tuft, which was myosotis, then at another, touching, which was eritrichium, but eritrichium with 1½in. stems, not prostrate as is usual on the silver fur. Some say that Myosotis rupicola is only legendary on the Alps; but here (as on the Pordoi) was something that, in the absence of a morphological botanist, was neither eritrichium nor Myosotis alpestris.—E. ENEVER TODD.

COLOUR NOMENCLATURE

LAST year I wrote a few remarks on the question of colour nomenclature; but this subject is so important that, now that the planting season is coming around again, I must return to it. The other day I spent a very pleasant—though wet—day at the trial grounds of one of our best known seed raisers, and I was struck by the difficulty that this and other firms must have in describing the colour of the plants catalogued in their seed lists.

As tastes in colour vary almost with every individual, it is obvious that firms that specialise, particularly in annuals and herbaceous plants, have to stock as great a range of colours as possible in order to satisfy every customer. Some of the shades I saw I, personally, did not approve of, but these firms sell the seed, and so there is, obviously, a demand. It is impossible to train a colour taste, and, in any case, it would obviously be wrong to attempt it, for colour, above everything, is a personal matter, and as such should not be criticised.

It is curious that our colour vocabulary has not kept pace with the demand for new colour names. In these days of new inventions our vocabulary has been able to adapt itself either with new words or with fresh meanings for old ones. Broadcasting, the motor car, photography have now all got their own vocabulary—not so the colour names of plants. Botanists and raisers of new plants have been so lavish with their naming of new species and varieties, and are so proficient at coining new names, that it is certainly their duty to settle this extremely muddled question of plant colours.

It has been said that were new names invented no gardener would use them, but I maintain that they would have to, out of self-defence. Dyers have evolved their own names, but these are hardly suitable for ordinary use, as most of them are founded on the chemical constituents of a particular dye, and so are difficult, if not meaningless, to the layman.

Some society which is sufficiently strong to make its decisions felt—the obvious one is the R.H.S.—might convene a committee consisting of an amateur, a member of the trade, a botanist, a painter and a dyer, who could discuss each colour in turn, do away with anomalies, fill up gaps in our vocabulary, and, perhaps, issue a chart of each group of colours. It is obvious that some colours are more important than others. Blacks and whites could be left out; greens and greys would come low in the list; while those of primary importance are those centring on red—a loose name which means little—blue and yellow in order of importance.

If we take the red group, practically the only names in existence are blood red, usually misnamed; crimson, probably the most accurate; scarlet, also accurate, but could be subdivided; magenta, often misused, and in great need of subdivision; carmine, which is given in dictionaries as a beautiful red or crimson pigment—a poor definition; salmon, often misused; brick red, the same; and rose, pink and blush, which all want subdividing. If, instead of the eleven terms in existence, we had twenty-four definite names which everybody understood, much of the difficulty of colour names would disappear, for the reds are in the greatest state of confusion. The same applies to a slightly lesser extent in the case of blues and yellows.

Naturally, a chart of printed colours would be expensive to produce; but would a chart be necessary? Would it not be possible to find sufficient flowers whose colours are stable to supply us with names? Some are in use already, although in many cases the use of the flower name has given rise to difficulties. Buttercup yellow and primrose yellow are, however, almost perfect examples: both are common flowers and are stable in colour. Rose may have given rise to a definite picture many years ago, but is useless now. Gentian blue is also doubtful in meaning, owing to the introduction of so many new species. Presumably it was called after either G. verna or G. acaulis. Surely it would be less confusing if it was called verna or acaulis blue, which would bring a definite picture to every gardener's mind. In time, no doubt, the word yellow or blue would be left out, and the names buttercup, primrose or verna come into general use. In any case, if such a scheme were possible, it would do away with the common use of hyphenated names like rose-lilac and primrose-orange, which are extremely misleading and also are not standardised in any way.

By some such scheme as this, both the description of plants and the catalogue orders would be vastly simplified. This subject is of such importance to all gardeners, particularly when speaking about an ordinary plant that is not in general cultivation, that we should welcome correspondence on the subject.

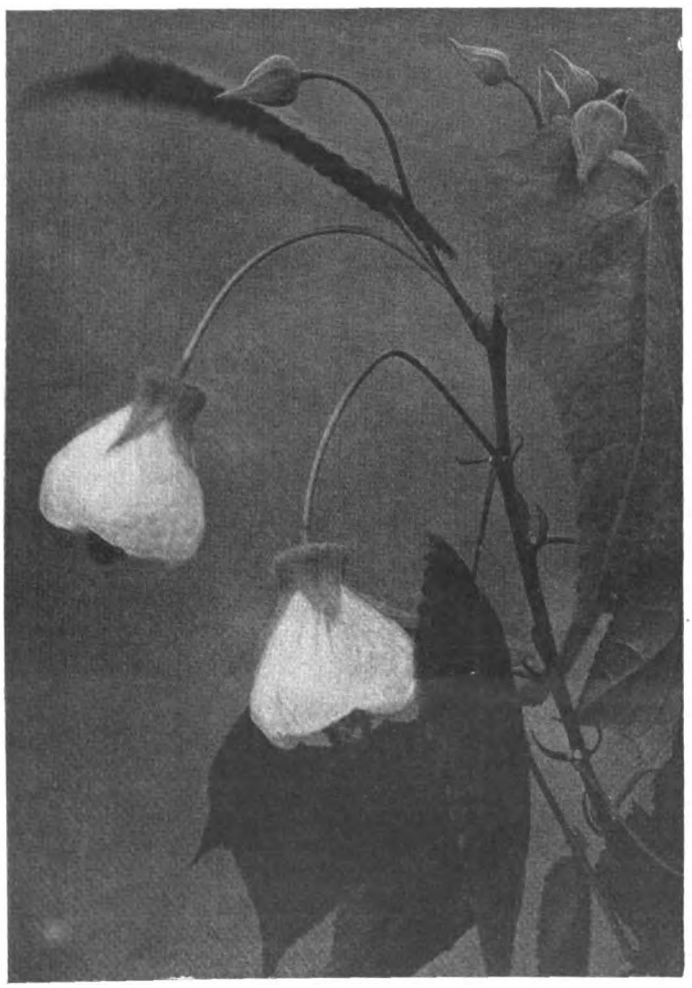
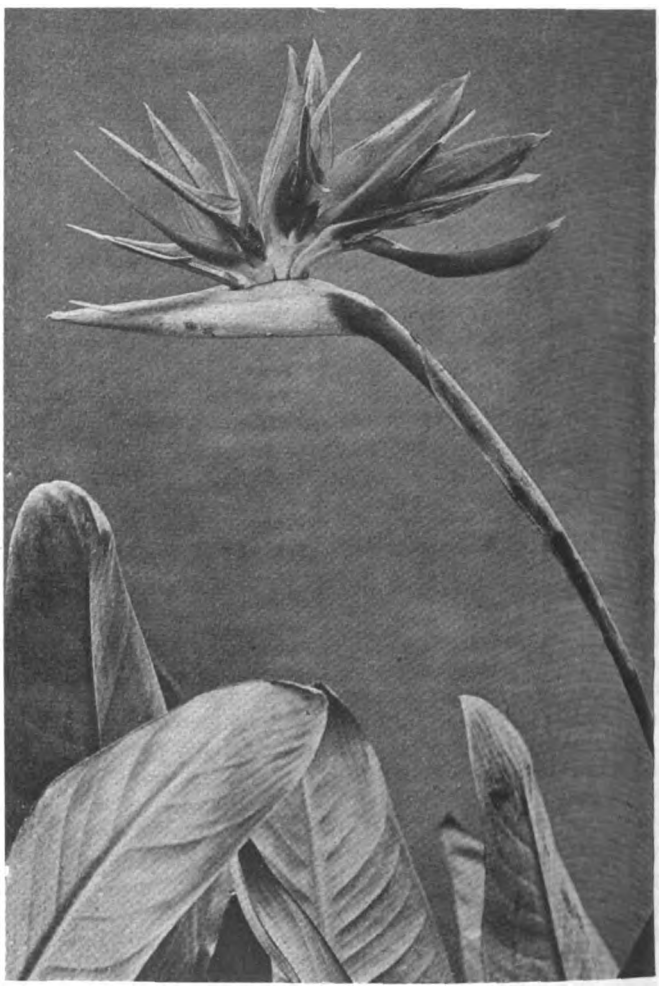
SOME FOLIAGE PLANTS FOR GREENHOUSE AND CONSERVATORY

PLANTS with ornamental foliage play an important part in the decoration of the conservatory and greenhouse, either as permanent occupants of the structure, as large specimens in pots and tubs, or planted out in the beds and borders. They are also of prime importance for furnishing the stages, where their chief function is to give variety and relief to the groups of flowering plants. There is a large number of plants well suited for this purpose, although it is doubtful if their value is sufficiently realised in most establishments. Most of them, as will be indicated, are easily propagated and grown, either from seeds, cuttings or division.



A FINE WHITE ABUTILON.



THE CURIOUS-LOOKING FLOWER OF STRELITZIA REGINÆ.

CORDYLINES, more generally known as dracænas, furnish quite a number of useful and beautiful plants for this purpose. C. australis and its varieties—often incorrectly listed as C. indivisa—in their smaller state prove very useful for the stages, and for house decoration; as they attain larger proportions they make handsome specimens for furnishing the beds and borders. A batch of seedlings show considerable variety in leaf character. The typical green-leaved forms are very useful, but the purple-leaved and variegated forms are most prized. Two purple-leaved varieties are known as purpurea and lentiginosa. There are also two with variegated leaves, *viz.*, C. Doucettii and C. de Grootii, the former with white stripes, the latter with white and red stripes. Other species and varieties are C. stricta, a slender and graceful species with green leaves, grown in small pots; it is very useful for conservatory or house decoration. C. Haageana and C. cannæfolia are also handsome and useful species, while C. Bruantii and its variegated variety are very largely grown for market. The large growing varieties, when they become bare and leggy, may have their stems cut half way through, just under the crown of leaves. If a ball of moss is bound round the cut portion and kept moist, roots should soon develop from the stem above the cut. The top may then be cut off and placed in a suitable sized pot, standing the plant in a warm, moist house until established. Cordylines are also propagated from "toes"—often wrongly called roots—but really underground stems. Old plants generally furnish a number of them. They should be cut off and laid in fibre, in a hot-bed, where they soon start into growth. The more slender species and varieties may be propagated in the same way, also by cutting the stems into short lengths, and placing them in fibre in a hot-bed, where growth should start from every joint.

LIRIOPE SPICATA VAR. VARIEGATA.—Grown in 5in. pots this plant is very useful for decorative work. It also, when planted out, makes a beautiful edging for beds or borders in the conservatory. It is easily increased by means of division, and should be grown perfectly cool, for if placed in a high temperature it refuses to grow and forms a hard bud on the crown of the plant.

ABUTILONS afford some useful plants for our purpose. A. insigne, with huge green, rugose leaves and long drooping sprays of crimson flowers, with darker veins, is very handsome for furnishing pillars or rafters. A. Thompsoni, with handsome leaves, mottled green and yellow, is very useful, as also is the smaller growing A. Savitzii, with green and creamy white leaves. The slender-growing A. vexillarium var. variegatum is ideal for

Digitized by Google

furnishing pillars or rafters, as also is the hybrid A. Milleri, both of them also flower very profusely.

ACER JAPONICUM VAR. AUREUM, and all the beautiful varieties of A. palmatum, are beautiful for a cool house, and they can easily be brought on early by gentle forcing, as also can A. Negundo var. variegata.

AGAPANTHUS UMBELLATUS VAR. VARIEGATUS is a small growing variety, with white and green banded leaves, that is very pretty and easily propagated by division.

AGAVE AMERICANA and its varieties are too large for the ordinary greenhouse, but have their use in the large conservatory; while large plants are handsome for standing outdoors during the summer.

ALBIZZIA LOPHANTHA, with its graceful foliage, is very useful for decorative work, and is easily raised from seed sown in a temperature of 60° during February or March.

AMARANTHUS BICOLOR, HENDERI, SALICIFOLIUS AND TRICOLOR are all annuals with beautifully marked foliage. They are easily raised from seed sown during March and are very useful for the summer months. Free exposure to light is essential to develop their bright colours.

ASPARAGUS SPRENGERI PLUMOSUS and its varieties, A. decumbens and A. virgatus, are all easily raised from seed sown in a warm house, and are all invaluable for grouping or for supplying cut sprays for decorative work, while A. Sprengeri and A. decumbens make beautiful basket plants.

CANNAS, especially the dark-leaved varieties, are very handsome when grown into large specimens.

CENTAUREAS RAGUSINA (CANDIDISSIMA) GYMNOCARPUS and CLEMENTEI are all plants with grey foliage, much used for summer bedding. They are, however, equally useful for the cool greenhouse, and are all easily raised from seed.

COLEUS in many varieties are so well known that they only require passing mention.

COPROSMA BAUERIANA VAR. VARIEGATA is very beautiful when well grown, and is propagated by means of cuttings, which are best rooted in a close case with good bottom heat.

CYPERUS ALTERNIFOLIUS and its variegated variety are very useful, the latter being best increased by division, the former being easily increased by the whorls of leaves being inserted as cuttings.

EUCALYPTUS GLOBULUS and E. PULVERULENTA, are both easily raised from seed, their glaucous grey foliage rendering them very handsome for decorative work. E. citriodora, although green, is worth growing for its fragrant foliage.

GREVILLEA ROBUSTA and JACARANDA OVALIFOLIA SYN. MIMOSÆFOLIA, with their slender, graceful habit, are ideal for decorative purposes, and are easily raised from seed sown in a warm house during February.

FICUS ELASTICA and its variegated variety are popular for greenhouse and house decoration, while F. macrophylla is deserving of more general cultivation, as it branches freely and is not such a heavy looking plant. Both are easily propagated by means of cuttings placed in a warm propagating case.

LOMATIAS FERRUGINEA and SILAIFOLIA are both beautiful foliage plants, either grown in pots or planted out in a cool greenhouse. The latter is a low-growing plant with finely cut foliage.

ROUPALA POHLII SYN. CORCOVADENSIS.—This handsome plant is generally regarded as requiring stove treatment, but it stands perfectly in a cool greenhouse, in fact, the writer has had plants kept in perfect condition for two years in an ordinary living room. It is very useful as a small plant for decorative work, and may also be grown into a large specimen. The young growth, covered with a rich brown tomentum, being very beautiful. This plant is propagated by means of the smaller side shoots, plunging the cutting pots in close case with plenty of bottom heat at command. The wood is very hard and cuttings usually take several months to root.

RICINUS COMMUNIS, the different varieties of the castor oil plants, are easily raised from seed, and prove very useful for furnishing during the summer months,

STRELITZIA REGINÆ.—This South African plant is very handsome when grown in large tubs, but is seen at its best when planted out, when its noble foliage will attain a height of 4ft. to 5ft. In addition, there is the charm of the extraordinary looking flowers in orange and dark blue, which are produced over a long period.

There are many other plants suitable for our purpose which space forbids me to mention, but from the foregoing it will be seen there is no lack of beautiful foliage plants to choose from.

J. COUTTS.

NOTES FROM FLORAIRE

THERE are, among the Martagon group of lilies, some members with yellow flowers, such as LL. pyrenaicum, Jankæ and albanicum. The first is well known and grown in every alpine garden. The two last come from the Balkans and are seldom seen in cultivation. L. Jankæ grows in the alpine meadows on the summits of Bosnia, Serbia, etc., and is a fine plant with bright yellow flowers, smaller than those of L. pyrenaicum and much deeper in colour. It differs still more from the latter in its richly striated petals, its red anthers and its leaves, which are shorter and less numerous. It was described by Kerner in 1877 (*Oest. Bot. Zeit.*). The dimensions of the whole plant are modest, and never so large as those of L. pyrenaicum.

Lilium albanicum (*Griseb.*) differs by its yellow anthers, and its petals, which are pure yellow and never striate or punctate. I cannot understand how the "Index Kewensis" identifies these two lilies as synonymous with L. chalcedonicum, since they differ from it considerably even at first sight and require quite a different method of culture. They flower, too, at different times of the year, *i.e.*, May-June; while L. chalcedonicum does not flower before July.

PINGUICULA LONGIFOLIA AT FLORAIRE.

Last April we had here some beautiful flowers of the rare Fritillaria Moggridgei. It is a splendid form of F. tubæformis, having large lemon yellow pendent flowers, with brown spots arranged as in a mosaic. They are much larger than those of F. Meleagris. It is seldom seen in gardens, and is even rare in nature, growing in the eastern part of the Maritime Alps, where it is found in association with F. tubæformis.

Pinguicula longifolia is the largest flowering species of this genus found in Europe. It has long yellow leaves, which can be seen from afar, and large sky blue flowers, bigger than those of P. grandiflora, and with a large whitish blue spot in the centre. It is also an uncommon plant, and grows here and there in the Pyrenees, but very seldom in the Maritime Alps. I found it abundantly in the damp crevices of the Ordesa Valley in the North of Spain (centre of the Spanish National Park

Digitized by Google

at Arrazzas), in the Pyrenees, on the north side of the rocks forming the Cirque de Gavarnie (Hautes Pyrénées). It is certainly the best of the pinguiculas.

The aquilegias were good this year. A. alpina, with its very big sky blue flowers (whitish petals) and its finely divided and small foliage, was beautiful in June and July. A. pyrenaica has smaller and deep blue flowers with rich gold anthers and small round leaves. The first must be grown in shady places, while A. pyrenaica requires a sunny situation. A. glandulosa is the gem of the genus with its erect, deep sky blue flowers, which are greatly enhanced by the slightly glandulous leaves. The seeds, instead of being shining black, are unpolished.

I have often been asked about the natural habitat of Daphne rupestris = petræa. This plant always grows in steep limestone walks facing east and south, and at Floraire, where it is luxuriant and flowers abundantly, it grows in limestone walls. We have it at its best in the tufa wall, where it is quite at home, but it never seeds. It does better on its own roots than when grafted.

We have great trouble with Campanula Morettiana and C. Zoysii, which are eaten by slugs. These pests come from miles off to eat these rare herbs, which they like better than anything else; but, curiously, they do not touch C. excisa, the leaves of which seem to be more tender than any of the others. C. excisa, which comes from the Simplon range, is peat-loving, of course, or ought to be. But, here, it does well everywhere, asking only for a wall and sun. It seeds abundantly.

Iris Cengialti is a very dwarf and graceful iris belonging to the aphylla group. It covers a large rocky area on Monte Cengialto, near Roveretto in Tyrol, adorning it with its large deep sky blue flowers, flushed with purple. The beard, instead of being white as in I. aphylla, is orange yellow, and the plant does not exceed, in its natural state, more than 6ins. in height. It is a good iris for the wall and rockery.

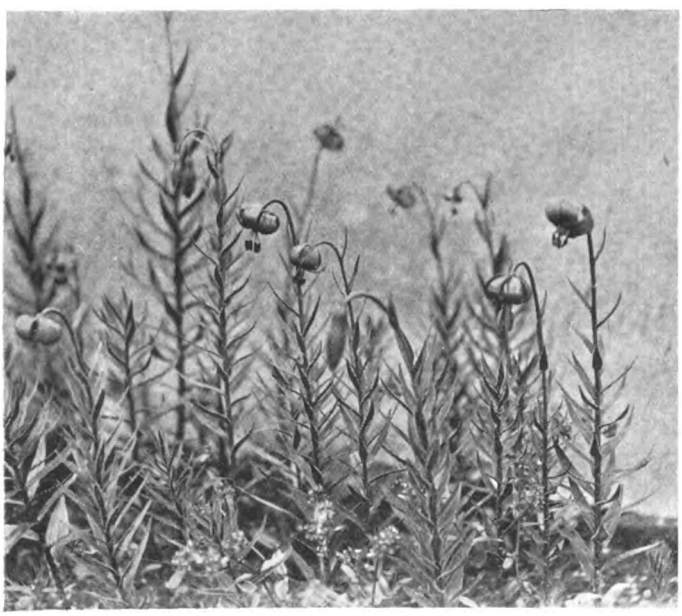
GENTIANA PYRENAICA NEEDS SUN AND A MOIST POSITION.

I. rhætica was not known to me until 1915, when the Hon. Charles Rothschild wrote me to call my attention to it. It was described by Brugger of Chur (1878), and is an Engadine form of sambucina. I went to the Low Engadine, near Rhemus (at 3,600ft. elevation), to find it, but could not reach the high rocks where it grows and from where it seems to defy the poor botanist who admires its charms. Higher up there is the imposing ruined castle of Rhemus, destroyed in 1475, and I suppose the iris, which belongs to a group of east European origin, was perhaps grown by the ladies of the old castle 500 years ago, and that it is the only existing plant of their gardens. The fact remains that I. rhætica is very near to I. sambucina, from which it differs by its broader leaves, its larger flowers (blooming three weeks before I. squalens and I. sambucina), its sweet scent of Dianthus superbus, and its dwarfer growth. The peasants who live at the foot of the rock were able to get a little plant for me, and now it is well represented here.

Gentiana pyrenaica does not seem to be difficult to grow, but needs, of course, to be watered from below, as we do with G. bavarica and G. Rostani. It has flowered here, as can be seen from the illustration, but requires sun and a wet situation.

One of the best pictures in our garden at present are the tufts of Linum campanulatum mixed with Aphyllanthes monspeliensis. These two colours are very beautiful when placed together. Both plants want, of course, a dry and sunny situation and light soil.

Floraire, Geneva. H. CORREVON.



LILIUM JANKÆ. A SPECIES FROM BOSNIA.

THE GRAPE HYACINTHS—II

ONE hesitates to put in print one's disagreement with what is written in such a standard work as Bailey's "Cyclopedia of Horticulture," but I cannot see eye to eye with the statement that except Muscari botryoides, "all the other kinds described are fancier's plants, interesting chiefly to skilled amateurs." It is true that there is no elegans in the list, and that Heavenly Blue is omitted, but neglectum, racemosum and Argæi are sufficient, to my way of thinking, to prove the inexactitude of the sentence quoted. Muscari may equally well be grown by the veriest amateur as by the skilled fancier; or as well by the seeker after decorative effect, as by one whose aim is to have in his garden something out-of-the-way, or of botanical interest. When, however, Bailey says "the group needs botanical revision badly," I agree with him down to the ground. It does, indeed. It is this muddled state of affairs which has decided me to adhere to the catalogue names, which I have found in the Dutch lists of van Tubergen and van Meeuwen. No other list, English or Dutch, contains anything like as many. The names are given in alphabetical order. The old botryoides is not included for the simple reason that in my garden it is all over the place; nor have I forgotten its beautiful white variety, botryoides album, and its pale pink one, botryoides carneum. I am always in two minds about this last. On the whole I think I class it as one for Bailey's "skilled amateur." It is on a par with Scilla sibirica azurea, which to me is interesting, but washy. Sibirica alba, on the other hand, is a real gem, and as is said of so many good things, ought to be more widely grown than it is.

Propagation is effected either by off-sets or by seed. As I said in my previous article, there seems to be an opening for someone to take the family up and raise seedlings. The species and varieties other than moschatum and pallens would probably cross if planted near to one

Digitized by Google

another, or it may be that some reputed species are not species at all and would produce from seed interesting variations. How else came elegans, which originally was sent out by Max Leichtlin? or my very taking pale blue Turquoise? or it may be the variety cracked up in "My Garden in Spring," or a more recent comer to Mr. Bowles's famous garden, the giant form of lovely colour which came to him from a Cornish garden?

And now for the list.

ARGÆI.—Late flowering, dwarfer than the majority, very dark blue bloom, but not quite as deep in colour as neglectum; white tips to blooms, abortive flowers at the top of the spike paler than the others, faint scent.

ARMENIACUM.—Late flowering, deep blue, fine and rather scanty foliage, spicy scent like Heavenly Blue.

ATLANTICUM.—Slender foliage, pointed thin spikes, rather like polyanthum, pleasantly scented, Bailey says the trade make Argæi and atlanticum to be synonymous, and that Baker could not distinguish atlanticum from neglectum.

COMOSUM.—A very curious form with the top sterile flowersborne on long pedicels, which gives the plant a sort of startled, hair-stand-on-end look, the last of my collection to bloom, in perfection in the third week in June, fertile lower flowers are a curious olive colour and the sterile top ones a pale washy violet.

COMOSUM MONSTROSUM.—The famous feather hyacinth, all flowers turned into long slender filaments of a pale lilac colour, excellent for growing in a cool greenhouse, about 12ins. to 15ins. high; there are several synonyms, *e.g.*, plumosum or monstrosum with the comosum dropped, late to flower.

CONICUM.—Deep blue with conspicuous white mouths to the bells, shade like elegans, what scent there is is not very nice and quite distinct from Heavenly Blue, which is said to be a form of this species.

COMMUTATUM.—Very distinct, much dwarfer than any other and the flower spikes small, a pretty Uppingham blue, looks the very thing for a rock garden, faint scent.

MUSCARI HEAVENLY BLUE.

ELEGANS.—Probably a seedling distributed by Max Leichtlin, darker blue than racemosum, exceptionally free, not much scent, a *most* desirable variety.

HEAVENLY BLUE.—Probably a conicum seedling, delightful shade of blue, long pointed flower spikes, strong clove scent, "too well known to need any description."

HEAVENLY BLUE SEEDLING TURQUOISE.—Came by chance in a bed of Heavenly Blue in my garden, an exceptionally lovely shade of turquoise blue, so I called it Turquoise, delightfully sweet, most distinct.

HELDREICHII.—Large individual bells of a pretty medium blue with white mouths, not many on a spike, rather miserable looking owing to the sparseness of the bells on a spike.

LATIFOLIUM.—Most distinct, only one leaf, tall flower spike, a great contrast between the top and bottom flowers in their shade of colour.

MOSCHATUM.—The musk hyacinth, very sweet, four or five spikes in a vase diffuse a powerful scent like a poetaz narcissus, flowers begin life as a curious greenish purple, getting quite a yellow look with age, a late frost affected the spikes, they bent over and never regained their upright position.

MOSCHATUM MAJOR.—As I have it, it was indistinguishable from moschatum.

MOSCHATUM FLAVUM, or MACROCARPUM.—The flowers begin life as in moschatum, but in the end turn a real yellow. I was much impressed with a bed saw in Haarlem at van Tubergens this spring.

NEGLECTUM.—Very dark blue, quite as dark as paradoxum, white mouths to bells, sweet with a scent of its own; as a matter of fact hardly any two in my collection had the same scent.

PALLENS.—Totally unlike any other, flowers open-shaped and of a dirty white colour, much crabbed because the bottom flowers are over long before top ones open, best known as Bellevalia romana. Is it a Muscari?

PARADOXUM.—Very late, extremely dark, sugar-loaf flower head to spike, hawthorn scent, no white in bells, very distinct.

PARADOXUM ALBUM.—A so-called white, really a greenish cream, best part of it its nice hawthorn scent, looks its best at night, whereas all the blues look very much their worst then.

POLYANTHUM.—So mixed that I never decided upon the true one. I think it is one with a long pointed flower head to the spikes.

RACEMOSUM.—The first to bloom, so very sweet, very dark, but paler than elegans, an excellent muscari. Very free.

VULGARIS CŒRULEA MAJOR.—Probably the freest flowering of all, very dark blue bells with most conspicuous white mouths, the plant looks as if it were in mourning, scentless, top flowers of spike paler than the others, late to bloom.

So ends my list. It will be gathered that some of the above are of no use for garden decoration, but, on the other hand, are of much botanical interest. "You pays your money and takes your choice." I think I would go for elegans, Heavenly Blue and racemosum as a start if I had no grape hyacinths in my garden, and cast longing eyes on Turquoise. If I had glass, comosum monstrosum might be included, while if I had a rock garden, commutatum would be bought.

JOSEPH JACOB.

NOTES OF THE WEEK

DOUBLE AURICULAS: ONE OF THE OLDEST OF DOUBLE PLANTS.

LOVERS of uncommon and out of the way varieties of favourite flowers are frequently on the look-out for forms which they have not previously grown but which, apart from their rarity, possess points of beauty to their eyes. Such are the double auriculas, although the true devotee of the auricula despises them as "monstrosities" and not to be spoken of in the same breath as his favourite stage or alpine auriculas with their refined single flowers, so exquisite in every way. Yet those who have grown these double varieties seem to acquire an affection for them, and, if they should lose them, regret their disappearance from their gardens. Although difficult to procure from the nursery trade, there are a fair number of varieties in cultivation, and a brief mention of them may be of interest. Before discussing the varieties, the question of culture may be mentioned. This is not difficult either in frames or in the open, but care should be exercised to propagate the plants from offsets annually, or, at the very latest, every two years so as to be sure of having spare plants to take the place of any which may be lost. These double auriculas have been known for many generations, and mention is made of one double one in Rea's "Flora," published as far back as 1665, in which he gives a brief description of a yellow auricula with double flowers. I do not think the double yellow one of the present day is a direct descendant of Rea's plant, as the latter had only four or five double flowers on a short stalk, while that now in cultivation with yellow blooms has a greater number on a fairly vigorous stalk. In addition to the double yellow one now in cultivation, there is a very dark coloured double sometimes called the double dark crimson and sometimes the double black one. It possibly lacks brightness. There is a curiously pretty double green auricula and also a double grey. The double lavender auricula is quite pleasant in its colour, and the double blue has many admirers among the growers of these interesting flowers. Were a demand to exist for these flowers, no doubt there would be a considerable accession to the number of varieties, as the methods adopted for raising new double primroses would doubtless be effectual with the auricula as well. There is a very good illustration of one of the double auriculas in Dr. Macwatt's valuable work on "The Primulas of Europe" opposite page 153.—S. ARNOTT.

THE OLD-FASHIONED DOUBLE AURICULA WHICH MANY GARDENERS CONSIDER SO CHARMING.

POULTRY IN GARDENS.

Advice for those who have no space for hens other than garden or orchard.

IT is an old adage—hens are poor gardeners. Undoubtedly, if not kept under control. But this fact should not prevent their being kept in properly constructed runs, with wire netting sufficiently high to keep them from flying over, and housed in a neat, though not necessarily expensive erection. A factor which should induce gardeners to keep fowls is that ordinary farmyard manure and, indeed, horse manure as well, is becoming increasingly difficult to obtain even in country districts. All that is necessary is a board for the droppings fitted under the roosting perches and scraped daily, the board sanded and the manure stored away in a dry place for future use.

It is unwise to spread it on the land in a fresh state, especially during the growing season, as its newness is too hot for roots in activity. It does less harm to dig it in in winter, but even then it must be remembered that much of its valuable property is lost and washed away before it is taken up by plants. It really should be kept in wood boxes in a potting shed or other outhouse and crushed when dust dry, then kept in air-tight canisters. The French reduce it to a powder and call it "pudrette," in which form it is evenly distributed to active vegeta tion. In this form it is as good as, and better than, some of the advertised patent fertilisers now on the market. I infinitely prefer it to canary guano, which it so much resembles.

That poultry are welcome in the orchard or portion of the garden set apart for growing pears and apples goes without saying, since in addition to the potent manure they drop they are ever on the look-out for insects, which would otherwise find a lodgment in the crevices and bark of the trees. With regard to the so-called unsightliness of hens about a garden, surely this is more apparent than real, as many methods are at the disposal of the cultivator of the soil to minimise, and in summer altogether obliterate, them from view, viz., for summer blooming I suggest tall nasturtiums, Ipomœa coccinea, Tropæolum speciosum (if you can get it to grow) or even sweet peas up the wire-netting; and for permanency a hedge, say, of Cupressus Lawsoniana or beech trained to grow erect and ultimately to reach 7ft. in height. These and others suggest themselves as being not only a means of hiding the fowls from view, but of affording no little protection and shelter to both poultry and garden. Briefly, points to remember are: Stick to one breed; they look infinitely better than a mixed piebald lot, and if the run is small, do not go in for too many birds. White Wyandottes or Buff Rocks are hard to beat for confined runs because of their hardiness, docility and winter-laying qualities of large eggs. They are heavy birds, consequently are not "high flyers" and never even make the attempt to mount the 5ft. wire netting.—E. E. P.

TWO KINDS OF GARDENER:

The Decorative and the Individualist.

GARDENERS are as various as the gardens they make, and no two gardens are quite alike, but all gardeners, or nearly all, incline to one of two types, sharply contrasting in their aims and only agreeing in their more or less tolerant contempt for one another's ideals. One type appreciates flowers in the mass, the other appreciates them individually.

The first type uses flowers as pigments with which to paint designs in glowing or subtle colours. Form is supplied by fastigiate yews, rounded masses of evergreen shrubs and the aspiring lines of hollyhock and delphinium. His garden is thus an extension of the house, in which the decorative idea is carried out on a larger scale and with more frequent changes; it is one coherent picture, or it may be a series of pictures, separate from one another like the rooms of a house.

For the other type of gardener each plant has an individual beauty, and though he may seek to enhance this by careful choice of setting or background, he does not mass his plants into any extrinsic design, and if any design appears in his grouping, it will be an extension of the design that is contained within the plant itself. His garden is, therefore, like a collection of miniatures, mostly unframed, and may seem uncomfortably incoherent, or even disorderly to the other type of gardener.

The two types of gardener run easily to extremes. The first reached his zenith, or nadir, in the heyday of bedding out, when a long-lasting blaze of colour was the ideal and the plants were dug up as soon as their flowers faded, to be replaced immediately from the battalions kept in reserve. The expense of this style of gardening, and a stigma of vulgarity that it naturally acquired, combined to suppress it. But it soon burst out in another form and is still with us, for many modern herbaceous borders are about as restful as a firework display and often less coherent. Dorothy Perkins and the Crimson Rambler played cheaply into the hands of the garden decorator, who drapes the garden with them as easily as you may festoon a room with cut paper at Christmas time, and with much the same effect. Broad drifts of colour have this drawback, that if they are used unskilfully they produce an actively unpleasant impression, while the effect of many colours set together, even though haphazard, is almost always pleasant. For this last reason a cottage garden seldom fails to make a beautiful picture, though it may be a jumble of colours and planted with no thought of design.

The extreme gardener of the second type makes a collection of plants rather than a garden, and the area round his house is disfigured with hand-lights, panes of glass and inverted jam jars. Rare alpines flourish on heaps of road metal or in tin baths filled

Digitized by Google

with broken slate, and delicate woodlanders are screened from the wind by strips of linoleum. The collection is overgrown with weeds, for which he has a morbid tolerance, alleging that plants like company, and low company as well as any other, so that the visitor may be surprised to find the stylistic beauty of a regalia iris set off by the dowdiness of groundsel or chickweed. The extreme type of all grows plants only because they are difficult and loses interest in them when they begin to flourish.

Both types insist that they grow plants in a natural way, and this is certainly true; but they grow different kinds of plants. Flowers may be divided, among other ways, into bee flowers and butterfly flowers. The bee prefers a plant with flowers set conveniently close together, growing in large colonies and provided with any kind of scent that will distinguish flowers that might otherwise seem alike to its short-sighted eyes. The butterfly blossoms, on the other hand, are each of them an impressionistic sketch of the scented and painted butterflies themselves, who use them less in order to secure a meal than as places for rest and dalliance.

The decorative gardener tends to prefer the bee flowers, and the individualistic gardener the butterfly flowers, so that a blind man, on a fine summer day, might distinguish between characteristic gardens of each type by his sense of smell and hearing.

The two types of gardening are by no means incompatible, but may be perfectly combined, and they will always be found interacting in the most satisfying kind of garden, the garden that appeals most quickly and surely to the average visitor who is neither an extremist nor altogether unregarding.—F. A. H.

TWO FINE DEUTZIAS.

OF the many forms and species of deutzia in cultivation, the two I have found most satisfactory are:

Deutzia Wilsoni.—A shrub about 6ft. high. Leaves 2ins. to 5ins. long, ⅛in. to 1½ins. wide; young branches are slightly scurfy at first, becoming dark reddish brown, the bark peeling. Flowers white, in corymbose panicles, each flower about 1in. across. Native of western and central China, introduced by Wilson about 1901. This species is a handsome shrub of the discolor group, free-flowering and quite hardy.

Deutzia corymbosa.—A shrub of about 9ft. high, of vigorous habit. Leaves ovate with long tapered point, 2ins. to 5ins. long, 1in. to 2½ins. wide, green on both sides. Flowers crowded in a corymb 2ins. to 3ins. across, each flower ⅝in. in diameter. Petals white with large conspicuous yellow anthers. The flowers have a hawthorn-like scent, and form compact full clusters on the previous year's branches, in July. It is one of the hardiest deutzias I have.—ANDREW HARLEY, *Fifeshire*.

DEUTZIA CORYMBOSA IS ONE OF THE HARDIEST OF THE GENUS.

DEUTZIA WILSONI, ALLIED TO D. DISCOLOR.

GARDENING IN FORD "E" BARRELS.

WHY Ford "E" barrels and what is Ford "E"? I can hear you asking. The answer to the first question is because they are cheap, you can pick them up at almost any garage for a matter of five shillings or so. They are stoutly made to contain a particular lubricating oil, used by all Ford drivers, which answers your second question.

When you have caught your barrel, draw a line round its middle very carefully so that it meets exactly, then slowly but surely saw along this line, until the barrel is sawn asunder. This, I may say is none too easy to do, but it is not impossible. Then bore four or five nice half inch holes in the bottom of each tub so formed. Place some bits of broken crock on the bottom for drainage. Make up your mind where you want your tubs and place them on four half bricks, so that they are exactly level. There is a certain finality about this operation, simple though it may be, for when you have filled them with good mould the tubs are too heavy to be moved about with any ease. You will then find yourself in possession of two nice gardens and can commence gardening at once.

You will be surprised at the number of flowers which will flourish in these small, improvised gardens. The plants must, of course, be chosen in relation to the position of the tubs. Low growing plants for open positions, taller ones for each side of a doorway or to stand against a wall. Nearly all the year round you can have flowers in your tubs, but there is a little difficulty about the winter months, for the tubs are too big for box or bay clipped into formal shapes. The relative size of the tubs and trees does not give a pleasing proportion. Rosemary, however, looks quite well, if nicely grown so that the plants hang slightly over the edge of the tubs. Its fragrant spikes are always a joy winter and summer alike.

It is best, however, to plant the tubs ready for the spring with either bulbs or plants that will come into flower as soon as the returning sun warms up the earth. Wallflowers are admirable for this purpose and some delightful effects can be obtained by selecting the colours carefully. Polyanthus planted between them often lends additional charm. Or we may plant aubrietia of various shades to fall over the edge of the tubs and clothe their sides with a mantle of purple and mauve. Of bulbs we have plenty of choice. Blue hyacinths with forget-me-nots between, trumpet daffodils or any other of the narcissus family. Plant them thickly so that they hide the soil in the tubs when in flower. Yellow daffodils emerging from a mist of blue forget-me-nots is another suggestion.

If the tubs of wallflowers are standing against a wall on either side of a doorway, sweet peas raised in small pots may be slipped in between the plants, which will afford them a little protection, while they are settling into their new quarters. Then, when their protectors are removed in due course, they can begin to climb up the sticks which can be so placed to form a bower over the doorway. Evelyn Hemus is an excellent sweet pea for this purpose, being a vigorous grower it will soon form an archway round the door. You will be surprised how sweet peas thrive in a tub and at the quantity of flowers they will produce, if you keep them picked off regularly.

When the spring bulbs are over and have been removed from the tubs, you can put in proper bedding out plants. A standard fuchsia surrounded with ivy-leaf geraniums of all shades, pink, red and mauve. You can substitute a standard heliotrope for the fuchsia with equal effect.

The impression of perfumed luxury may readily be obtained by planting the tubs with heliotrope and scented oak-leaf geraniums.

Massed antirrhinums of chosen shades make a splendid splash of colour. You must grade them carefully so that the tallest are in the centre, the dwarf ones on the outside.

An unexpected success was gained by planting a couple of tubs with double annual larkspurs of all colours. They grew to a great height, some three or four feet, and then burst into bloom. The effect was enhanced by the dead white walls of the house, against which the colours showed up to perfection. Such colours too, rose, white, cream, purple, blue, lavender and violet. Many of the individual flowers rivalled their

Digitized by Google

cousins the perennial larkspurs of the borders. Between the larkspurs Chinese yellow violas clothed the bare earth of the tubs.

There are endless possibilities for the gardener in Ford "E" barrels, endless experiments to be tried. Some will be successful, and, no doubt, some will be dismal failures, but all will be of interest.—EDWARD CAHEN.

POTTING SPRING-FLOWERING PLANTS.

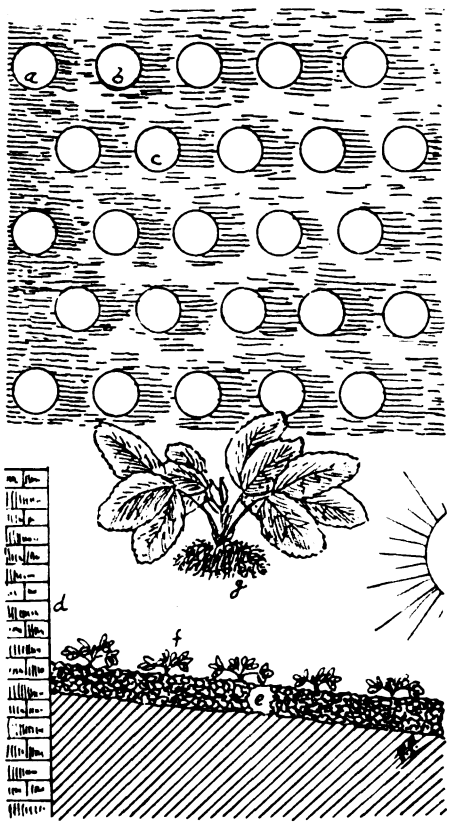
THERE are many kinds of plants deciduous, evergreen, and those that die off to the crowns, such as spiræas, that may be potted during the autumn and yield abundance of flowers in the spring for filling greenhouses and conservatories. Those that are to be subjected to a slight forcing temperature are all the better for having become established in pots first, that is, grown in the pots quite one year before they are introduced into a forcing heat. The more recently potted ones, those that have flower buds practically matured when the plants are potted—those that do not possess flower buds at that stage are useless—yield a spring harvest of blossom, but in doing so are much weakened, some being killed or rendered worthless and others requiring a year's care to regain their normal health. The plants include rhododendrons, azaleas, etc. But there are others, very beautiful, which can be managed by an inexperienced cultivator. Spiræas: S. japonica, white; S. palmata, deep rosy purple; S. palmata elegans, pale rose. The leaves should die down naturally, the stems being cut off, not pulled out. Pot firmly in loam and peat or leaf-soil. Solomon's Seal is another root that may be similarly treated. Other kinds are hydrangeas, H. paniculata, being very attractive; Hibiscus syriacus, the Guelder rose, daphnes, lilac, flowering currants, weigelas and the forced leaves of Prunus Pissardii to associate with the flowers. When any of these subjects are potted the pots should be plunged in ashes or sand on the north side of a wall and placed in a moderate heat as required after Christmas.

THE FINAL POTTING OF PLANTS: AN IMPORTANT OPERATION.

THE final potting of plants that are to remain in the greenhouse, conservatory, pit or frame or be plunged to the rims of their pots in ashes outside, during the winter months, should take place, as soon as possible after August comes to a close. In some instances it is better policy to leave plants rather pot-bound through the winter, than shift them to larger pots very late in the year. In cases where such plants are retained in the smaller pots a little judicious feeding will do them good during October and again after mid-January. Plants that have not fairly well filled their pots with roots by the early part of September should not be re-potted before January or February. There is an exception to this rule, and it applies mainly to cinerarias, primulas and calceolarias. If any of these plants are left in a pot-bound state through the winter months—to the end of February, for example—they will flower prematurely, yielding small trusses and flowers and proving very unsatisfactory. Unlike some kinds of plants, those I now specially refer to continue to produce young roots, practically throughout the winter. But it is advisable to make the shift from one pot to another as small as possible, so that the plants are kept progressing. Then, about the end of February, another re-potting may be very beneficial. The final potting of the winter-flowering batches should take place now. Strawberry plants, too, that are to be forced, should be finally potted as soon as possible.—G. G.

PLANTING NEW STRAWBERRY BEDS.

DIRECTLY the young plants possess sufficient roots to enable them to be detached from the parent plants they should be planted in their permanent quarters, after being placed on the north side of a wall or fence for one week. In this position they will not droop so much as in an open one and will soon recover from the check. Syringe the leaves twice on hot days and water to keep the soil nicely moist in the pots. Having prepared the soil beforehand by deeply digging it and adding half-rotted manure, put in the young plants while the soil is fairly dry, if possible. As strawberry plants are not, generally, profitable after the second year's crop has been gathered, there is no need to plant at a great distance apart, as is so often advocated. Make the surface soil rather fine to enable the workman to do



the planting easily and well. Plant 18ins. apart in rows, also 18ins. asunder, as shown in the sketch: *a* to *b* in the rows and *b* to *c* from row to row. These hints refer to plants grown in the open quarters. For an early supply of berries and where a suitable border exists, such as the one shown in front of a wall marked *d*, the border should slope gently to the south, and the surface soil, *e*, be well enriched with manure. Then plant 1ft. apart in rows 18ins. asunder, and make provision to protect the plants, *f*, from frosts. The letter *g* shows a really nice, well rooted plant.

PROPAGATION OF SHRUBS AND IVIES BY CUTTINGS.

OF course, this is a big subject, and would require a long article to make all details clear; so I will only refer to a few that will be helpful to those, inexperienced, but desirous of rooting a few in their own gardens. The best site is one facing due north on that side of a wall or fence. Around the base of each cutting there should be some sand, so, if the soil is clayey, it will answer the purpose if sufficient sand is placed around the base of the cutting. The soil should be well cleaned and have a slightly sloping surface so that water will not lodge there. For all except very large-leaved shrubs, the trenches may be 1ft. apart; but I prefer 18ins., then one can kill the weeds without disturbing the cuttings. When frosts come they always raise and loosen the cuttings, so that it is advisable to firm the latter by treading after the thaw comes and directly the soil dries a little. The wood most suitable for cuttings now should be matured; in very early summer it should be younger. Choice cuttings may be inserted in sandy soil in a cold frame. It will suffice if cuttings are severed just below ordinary leaf-joints, but the better way is to cut them off with a tiny heel of older wood attached. Use a sharp knife, remove the few lower leaves, fix the cuttings in an upright position in the trench, and always make the soil firmest against the base of the cutting. Hollies, veronicas and skimmias should be inserted in a frame, also any conifers; but laurels, aucubas, privet, willows, roses, flowering currants, etc., only require an open border.

PLANTS TO WINTER ON GREENHOUSE SHELVES.

TO the amateur, the greenhouse is, perhaps, a very important part of his garden, and his main interest is, probably, centred in it during the winter months. Frequently, one finds the greenhouse is over-taxed in winter—too many plants are crowded into it. In some structures there are too many shelves, in others too few. There should be a full complement of shelves, then great numbers of plants may be successfully wintered in the greenhouse. There are lobelias, zonal pelargoniums, ageratums, fuchsias, marguerites and other summer bedding-out subjects that always do nicely on shelves. In the sunniest position schizanthus plants will winter splendidly; and in the warm greenhouse, where plenty of artificial heat is at command, it is possible to keep the coleus, Iresine alternanthera and other heat-loving plants. Not many shelves should be empty. They are ideal for the pots of mignonette, stocks, antirrhinums and, later, after Christmas, bulbs and strawberries. Begonias, bouvardias, cacti, calceolarias, primulas, cyclamen, cinerarias, heliotrope, hydrangeas in small pots, kalosanthes and streptocarpus. Now, to be able successfully to winter the plants, they should all possess plenty of roots, or, in the case of cuttings, have a nice callus which will develop into roots early in the new year. It means that all applications of water must be given with great care, and in the morning only; stimulants should not be given, and air must be admitted without direct cold draughts on the plants.

VINES IN THE SOUTH.

IN smaller gardens, and sometimes in larger ones, the remark is made that the vines are unsatisfactory and not giving such good results as they might. One of the most common causes of failure is overcropping, not only in the young stage, but later on, when the plants have filled their allotted space. Here, however, the grower is not always to blame, and most of us like to see a heavy crop. Another principal cause is root action, and as so much depends on the roots, it is advisable to ascertain if these are in good condition and whether there is enough root fibre to supply the rods with food. Small berries, shanking, and bad colour are all due to improper root action.

September and October is a good time to deal with vines, and, as a rule, a portion of the border will need taking out and replacing with fresh material. Prepare a clean lot of drainage, loam well chopped down with a spade, crushed bones, and old mortar rubble.

Digitized by Google

A PICTURESQUE PLANTING OF THE GLOBE FLOWER.

The loam, rather on the heavy side, should form the staple, and to every cart-load add ½cwt. of ½in. bones, two ordinary barrow-loads of old mortar rubble, and a sprinkling of ashes from the rubbish fire. Thoroughly mix the whole, and protect from rain, as the compost ought not to be used in a wet state. If there are both an inside and an outside border, the former should be dealt with this year and the latter next season. Dig a trench 2ft. wide down to the drainage, and take the old exhausted soil away. Then the soil is gradually combed out with a rake or fork until a fair quantity of live roots are found, and during this process all stray roots must be carefully preserved. About three feet of new border will be ample, so build up a turf wall at that distance, and fill the intervening space with soil. Keep any roots fairly near the surface, and make the compost firm. During sunny weather shade the vines, and syringe them two or three times each day.

SOME VARIETIES OF THE GLOBE FLOWER.

THIS genus of trollius contains some very handsome plants for moist positions where the soil is deep and rich, although they will succeed in an ordinary border if the ground is fairly good and not too dry during the summer months. Perhaps the most popular is T. europæus, the common globe flower; and the garden kinds known as Fire Globe (bright orange), Orange Globe (rich glowing orange), Prince of Orange, Citron Queen, Excelsior (fine rich orange) and Gold Quelle, all producing globe-shaped flowers in various shades of citron yellow and deep orange. The plants attain a height of 18ins. or 2ft., the blooms standing well above the foliage. T. pumilus is a dwarf species from China with pale yellow flowers which are wide open, the whole plant growing about 6ins. high. This trollius blooms about June and July, and, as a rule, follows the varieties referred to above. T. yunnanensis is often considered a form of T. pumilus, but in many respects it is distinct, the scapes are branched, and it is in bloom later in the year. A native of China, the expanded golden yellow flowers are tinted with green on the outside, while the foliage is very distinctive. This plant is readily raised from seeds, and if they are sown when ripe, germination takes place almost immediately. One of the finest trollius is T. Ledebourii, a magnificent plant growing from 3ft. to 4ft. high, and the strikingly beautiful orange-yellow flowers appear when other members of the genus are over. It is a subject that ought to be represented in every collection. Trollius may be increased by division, which can be done in September, also from seeds, but in some cases it is twelve months before any seedlings appear.—T. W BRISCOE.

THE ORANGE PERUVIAN LILY.

ALTHOUGH a native of Chili, Alstrœmeria aurantiaca, the orange alstrœmeria, is popularly grouped with others of the genus under the name of "Peruvian Lily." It is one of the finest of the genus for the border, and has the advantage of being a good town plant. I have known it in confined town gardens and this summer I have come across a magnificent clump in one of these town gardens, growing 4ft. high, and with a wealth of its deep orange flowers streaked with brown or purple on the upper segments. This particular plant has received no special care and has been in the same border for a number of years without disturbance or the application of any fertiliser. The alstrœmerias, in fact, rather resent disturbance, and some of the most successful growers I know raise them from seeds and transplant the seedlings early to where they are to bloom. The tubers are rather brittle and are liable to injury when removed, and if ordered with bulbs, frequently arrive at a bad time of the year, when frost prevents planting them at once. If a plant can be procured in a pot all the better. This alstrœmeria varies slightly in colour and some forms are almost pure yellow and may be sold as A. aurea. It may be of use to some to say that A. aurantiaca does not run so freely at the roots as A. chilensis, but can be more easily kept in bounds. Personally, I have found it do admirably in a very dry, sunny place, with some old lime rubbish in the soil, but the latter ingredient does not appear to be necessary and may be omitted where not conveniently obtainable.—S. ARNOTT.

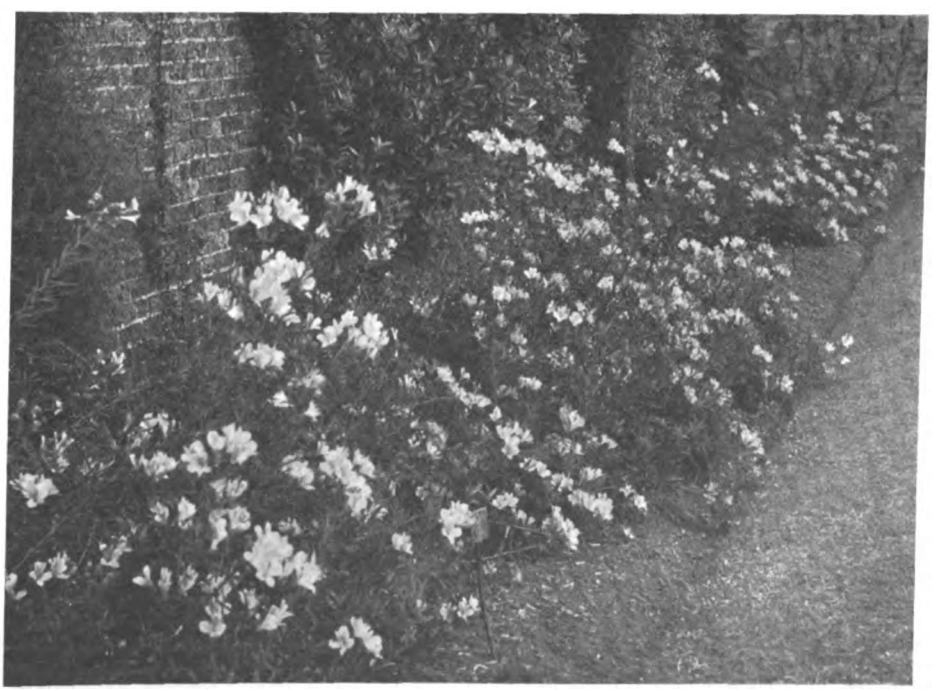
HARDY ANNUALS IN EAST OF SCOTLAND.

A FEW of the hardy annuals, which have done well sown and grown in the open beds and borders are—Campanula Speculum, Collinsia bicolor, Collomia coccinea, Matthiola bicornis, Nemophila insignis, Papaver umbrosum, Silene Bonetti and Sweet Alyssum. Some of these might be termed old fashioned annuals, yet they are quite charming and effective when well grown. It is certainly not necessary to have over-rich soil in which to sow the seed, as the borders in which some of those mentioned are growing have not been enrichedwith manure or leaf-soil for a few years and yet the plants have done well. Four of the plants mentioned are grown in front of herbaceous plants, where two or more patches of the same genus occupy stations at different parts of the borders.

Campanula Speculum is a pleasing and dainty purple-flowered plant, and is catalogued under the name of Venus's Looking-glass, but strange to say it is seldom seen in gardens; why this is I do not know, as it is by no means a miffy annual. A white-flowered kind, equally floriferous, is also to be had, and when seen from the distance one would conclude that a good strain of white lobelia occupied the ground.

Collinsia bicolor, may also be included under annuals seldom seen, yet it is one of the showiest and most attractive of plants.

Collomia coccinea is altogether out of the common yet it is not really a gaudy flowered annual, but there is something in the colour and appearance of the small flowers which arrests attention. Although called coccinea, I should describe the colour of the flowers as reddish pink. This collomia looks well when associated with Pentstemon Newbury Gem.—DAVID ARMSTRONG.



A BED OF THE ORANGE PERUVIAN LILY.

Digitized by Google

PLANTS IN A SOMERSET GARDEN

IN spite of one's expectation of a poor show of flowers this year after last season's wet and cold, it has been a pleasant surprise to find most shrubs have flowered with exceptional freedom. The New Zealand olearias, leptospermums, pittosporums and Clematis indivisa have all blossomed with the utmost lavishness, while earlier in the spring the Australian Prostanthera rotundifolia was literally smothered with violet flowers from top to bottom. On the other hand, the New Zealand cabbage palms (cordyline) have flowered very sparsely throughout the district, probably owing to insufficient ripening of the wood last year.

A very successful grouping has been a bed of true blue hydrangeas with a number of Lilium regale and Watsonia Ardernei planted among them. A fine form of Plagianthus Lyallii is growing in the same bed and gives it the necessary height. The hydrangeas are the variety of H. hortensis known as rosea (a form collected by Maries in Japan many years ago) and the French variety Radiant, both of which come a deep rich blue when planted in a lime-free soil with plenty of leaf-mould and a little peat added to it. Tropæolum speciosum accidentally found its way into this bed and wreaths the hydrangeas and lilies with garlands of its scarlet flowers. The lilies are all seedlings, now in their fourth year, and certainly help to show what an invaluable plant this species is; some of the sturdy stems have carried sixteen flowers. Just beyond the hydrangea bed a big bush of a very fine single variety of Rosa indica has made an excellent background to the picture. Perhaps the greatest interest in the garden this year has been the flowering of several Beschorneria yuccoides. Why this denizen of Mexican deserts should be stirred up to flower by last year's dismal behaviour it is hard to discover. Nevertheless, in April four plants began to show signs of flowering and sent up magnificent rose-coloured stems 12ft. in length and as thick as a man's arm. The rather insignificant green blossoms depend from numerous branches, and the whole effect is decidedly striking; it would be still more impressive if the stems would stand erect instead of lying almost horizontally. Some very tall eremuri were in flower at the same time as the beschornerias and added to the sub-tropical effect of this corner of the garden.

The scarce Bomarea multiflora has flowered more freely than ever before and there are still many buds to open. The great clusters of tubular flowers of red and yellow freely spotted with black are very handsome growing through a tangle of Rosa sinica Anemone, white clianthus and Lonicera Hildebrandtiana. A few seed-pods have already formed, and there seems a fair prospect of sound seeds being ripened. A plant of Iris Wattii growing at the foot of an east wall is carrying two seed-pods, apparently the first time that this fine species from Yunnan has borne seed in England. Iris japonica flowered very freely in the spring, but not a single flower has set seed.

A rather attractive feature at present is a group of the biennial Michauxia campanuloides planted among dwarf rhododendrons and alongside Lilium Henryi. This Michauxia suggests a 6ft. Canterbury bell plant carrying dozens of white passion flowers; not a scientific description, but it may convey some idea of the uncommon appearance of the plant to those who have never seen it. Primula helodoxa has astonished everybody this year by its vigour in quite a dry bed, doubtless thanks to the abnormal rainfall of last winter. Many self-sown seedlings have come up around the old plants and will replace those which have succumbed to the drought of July. Primula japonica and P. burmanica growing in the same part of the garden began to flag long before P. helodoxa, when the drought set in. A few year old seedlings of the dainty little P. chrysopa flowered in the bog-bed and made one wish for more of the cool lilac flowers on mealy stems. This species and P. chionantha seem to be the most generally satisfactory of the newer species of primula for the average garden.

The glowing flowers of Mimulus Whitecroft Scarlet have been freely borne for at least six weeks, and the plant makes a suitable carpet for the stems of Lilium Parda-Coldtii and L. Burbankii to spear through. M. cardinalis has grown with such vigour that it has become too coarse for association with lesser plants, and its 5ft. stems have had to be supported by stakes. The alpine form of Parnassia palustris (brought from the neighbourhood of Mont Cenis) is growing and flowering bravely in a sunk pan in the rock garden, where it receives an occasional soaking in dry weather. Although this is a distinctly neat and small form in its native haunts, under cultivation it grows just as large as our English grass of Parnassus, so beautiful on the cliffs at Whitby. The much vaunted pink Jasminum Stephanense has flowered here for the first time this year, and is rather disappointing; the flowers are not a clear pink in tone, but have a tinge of lilac which greatly detracts from their beauty. Possibly further crosses with J. Beesianum may result in better coloured forms.

A very charming little white campanula has made its appearance at the edge of a path and is scarcely distinguishable from the fashionable C. Hallii. This seedling is probably only a pusilla form, however, as there are no plants of C. Portenschlagiana very near.

Several small plants of Gentiana asclepiadea are now in flower and prove what a strong constitution this species possesses, for they were collected in June, 1923, near Le Lautaret, packed in a hamper with other plants, and took five weeks in the post before reaching their destination. Needless to say, very few plants in that consignment survived the ordeal of such a long journey, but every one of these gentians recovered.

The mild winter was favourable to the establishment of Musa Basjoo, the Japanese banana, which started into fresh growth early in May and continues to unroll its great leaves one after another. A small tea plant (Camellia viridis) which has been growing unprotected for the last three or four years appears to be becoming quite at home in a sheltered shady corner.

N. G. HADDEN.

EFFICIENCY IN HEATING APPARATUS

MODERN glasshouses possess many points of superiority over the structures in which nineteenth century gardeners grew their plants. Broad glass, minimum of light restriction, and labour-saving ventilating gear are examples of these improvements, but none is of greater value than that which is the outcome of skill and ingenuity on the part of the heating engineer.

The pleasure of possessing a greenhouse is sadly discounted when, through inefficient heating apparatus, there can be no leisure or freedom during winter evenings, and a spell of hard frost means anxiety and maybe serious loss of cherished plants.

Where an extensive range of vineries, forcing houses and plant houses is concerned the anxieties are increased and, furthermore, the running costs of an establishment become extravagant, for defective or inadequate heating apparatus invariably means waste of fuel, and that under present conditions is intolerable.

Those of us who can recall the days of the old flue-heating system are fully alive to the vast difference which the adoption of hot-water heating made to indoor gardening, but when the old type of saddle-back boiler proved itself a boon and blessing fuel was very cheap and labour cheaper. Garden workers sought but little relaxation from their work, and living in the bothy or the lodge, the man on duty took it as a matter of course that temperature must be maintained even though it meant a restless night whenever frosts were keen.

Conditions have changed and, honestly, we cannot regret the change to the extent of wishing a man should still, simply because he chooses a calling in which he finds interest, be robbed of a reasonable amount of freedom and recreation. We certainly lament the fact that many fine ranges of glasshouses have of recent years been allowed to stand idle and unproductive on the score of economy, especially as in a large proportion of such cases the sole need is for installation of an up-to-date heating apparatus.

A point that appears to be frequently overlooked is that, although cost of production is higher than it was some years back, value of produce has also increased, and actual instances have come before the present writer's observation

Digitized by Google

where excellent glasshouses stand idle, but where cash expenditure upon choice fruits, flowers and winter produce for the requirements of the household reaches double the necessary cost of production at home if only the antiquated boiler and defective pipes were replaced by apparatus of the best modern type.

Such an undertaking is a sound investment on a large establishment from an actual financial standpoint, to say nothing of the pleasure of having home-grown produce and of witnessing a transformation in the attractions of the gardens.

The modern tubular boiler, of which an excellent example is herewith illustrated, makes even stoking a congenial task, and is capable of securing the maximum of service in the way of heating power from the minimum of fuel. Furthermore, by means of excellent control of draught, which may be ensured by employing experts to install the apparatus, it is possible to utilise breeze, slack and the cheap grades of fuel with perfect satisfaction, while the more expensive anthracite coals may be so economically consumed that they are, after all, economical.

Further advantages in these modern boilers are simplicity of repair work. A damaged tube may be replaced with a new spare part with small trouble and expense, and the construction of furnace and flues is such that there is practically no risk of choking with soot or shale. Temperature can be regulated to a nicety, and with the fire once going and required temperature once obtained an intelligent stoker can bank up and leave his work with safety from evening till morning during the keenest frosts.

Sectional boilers of various patterns and makes are placed before the public by engineers of the highest reputation, and the two essentials to certain satisfaction are, first, to place the installation in expert hands; and, secondly, to have a boiler that is capable of heating a larger area than that existing.

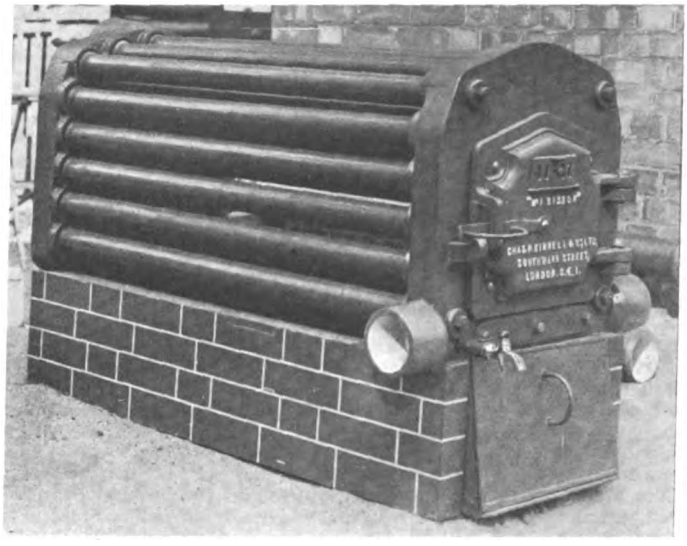
Allow the expert to decide the position and depth of the stokehole, the height of the chimney and the arrangement of pipes; bad setting and unscientific arrangement of pipes, bends, etc., have been responsible for much trouble and many disasters. The little additional cost of a boiler a size larger than the bare necessities demand is more than met by the economy in fuel effected by easy work instead of constant driving, while the life of the boiler will be prolonged and there is always the advantage of being able to extend a house or add a pit without overtaxing the boiler.

For very large installations it is possible to effect further economies by introducing electric turbines, which are inserted in the flow pipe close to the boiler. The turbine accelerates the speed of the water, forcing it through the pipes at such a pace that, after travelling round an extensive range, the water returns to the boiler almost as hot as it was when it started. The import of this is that when once the boiler is well heated an even temperature is maintainable with a very small fire.

Steam heating which is in general use in the large commercial establishments in America is under experiment in some of our large nurseries in the neighbourhood of London, and Mr. Engelmann, the famous carnation grower, is so convinced of its merits that after exhaustive experiment he is reorganising the whole heating system in his nursery, where the many acres of glasshouses will soon be heated by steam generated by four boilers. This is a matter of interest as showing the continual progress that science is making in horticulture, but for private establishments and amateur gardeners present-day types of hot-water boilers will prove adequate for many years to come.

Even the small tenant's fixture type of greenhouse should be equipped with a proper boiler and substantial iron piping; the flimsy oil-heated apparatus made of galvanised sheet iron and the like are poor makeshifts for a good upright or horseshoe boiler and flow and return pipes of 3in. diameter.

L. I. ATRIS.



A MODERN TUBULAR BOILER FOR THE GREENHOUSE.

CORRESPONDENCE

NEW GLADIOLUS.

SIR,—As you stated in your report on the Royal Horticultural Society's fortnightly meeting on the 25th inst., when we were given an award of merit for a new gladiolus which we had named White Lady, this name had already been appropriated for a gladiolus, and the award was made subject to our re-naming our new introduction. "Queen of Somerset" will be the name under which it will be known from now.—KELWAY AND SON.

THE PROTECTION OF OUR WILD FLOWERS.

SIR,—In your timely editorial article on this subject, you infer that such plants as the Royal Fern and Lady's Slipper orchid, if exterminated in a particular spot, could easily be re-established there later on, if desired. This would imply that the Lady's Slipper from the sub-alpine woods of Switzerland, from where the new supply would probably have to come, has exactly the same constitution as our north of England Lady's Slipper. Is this correct? Or is it more likely that the north of England plant has slowly adapted itself in the course of centuries to our north country climate, and therefore, if left alone, can hold its own, where the Swiss plant might not? My observations have led me to believe that nearly all our isolated colonies of plants, especially among the hills, have each an individuality of their own, and it does not follow that what will suit, say, a Dryas octopetala from North Yorkshire will equally well suit one from Skye. Or take Helianthemum canum growing at an elevation of 1,700 ft. on a Yorkshire hill and the same plant growing at sea level on the Lancashire coast, would the coast plant be likely to survive if transplanted to the hill station? I very much doubt if it would. If this is correct, it emphasises the need for more effective protection of our rarer plants in their present situations. But such protection, I think, to be of much good, must be, as you suggest, by public education.

Last year I saw the garden you refer to near La Grave, but one thing that it demonstrated was that it cannot be much easier to grow artificially many of the higher alpine plants, even at 6,800 ft., than it is in our lowland gardens. And anyone seeing these growing in their cultivated beds, after seeing them wild among the crags, might be excused if he thought he would just as soon see them pressed in a herbarium.

In this district we have lost more of our rarities, I believe, through drainage and the growth of industrial areas, than by any other cause, but some things I am afraid have been exterminated by the collector, such as the oyster plant from Holy Island, the Lady's Slipper from Castle Eden Dene, and the little fern, Woodsia ilvensis, from south-west Durham. In these cases one feels that it was done knowingly, and therefore all the more shame on those who did it.—R. B. COOKE.

[Mr. Cooke does not quite get the point of my remark about replenishment of old haunts. What I meant was that as plants like Daphne Mezereum and Osmunda regalis had been collected from the wilds to fill our gardens, so gardens might give again to the wilds. Plants are transplanted in any case, from high altitudes to gardens at sea level, and most of them succeed in some place or another. There are, of course, a few exceptions, like Eritrichium nanum—but even this has been kept alive in gardens on rare occasions. The only native that, I believe, has never been grown in a garden is Rubus chamæmorus, the cloudberry or averine. I was certainly wrong in quoting La Grave as an example of a national rock garden, for I had forgotten for a moment that in this

Digitized by Google

case the plants were collected in beds. I believe that the idea on Snowdon was to have planted them in their natural surroundings and then to have left them to their own devices.—ED.]

FREESIAS.

SIR,—I am glad to see "Clydesdale" is a freesia lover, and am still more pleased to see he prefers the named sorts to the mixtures. The mixed colours are useful for those who want to try a few as an experiment, and still more useful are they for cutting. They are splendid as cut flowers, last well in water and are most decorative. Mr. Avray Tipping writes a most helpful article on cut flowers. Has he ever tried freesias? I wonder if your correspondent Clydesdale has been really successful with F. Excelsior. I have never had any success with it. Chapmanii is a fine colour, but small. Has Clydesdale ever tried Daffodil, Apogee, Buttercup or Treasure, to mention a few commoner yellows? I think the blues and mauves he names are now superseded by better varieties. La Charmante is first-class and in place of Rosa Bonheur try Conquest, unless both can be afforded.

On page 494 G. G. gives some useful hints about growing freesias, but may I make a couple of suggestions. (i) Leave out the peat and leaf mould in the compost and add a little bone meal; (ii) *do not cover the pots after potting with any material whatever*. G. G. says, "Very frequently one sees freesia plants . . . with their stems and main leaves toppling over the sides of the pots; this is the result of bad potting. . . ." By covering the pots with ashes, sand, fibre, etc., you cause the growths to be weak and lanky, and then they topple over. Leave them uncovered, let them have plenty of air under a cold frame and the growth, as soon as it commences, will be strong and sturdy. I prefer just to cover the top of the corms, for the big fleshy main root—the contractile root—starts its growth immediately below the leaf growth and by having the top of the corm just below the surface the root grows straight down into the soil, and the deeper the pot the better it likes it, and the leaf growth has only a very little soil to force itself through.—G. H. D.

ASTER THOMSONI.

SIR,—I was very pleased to see the note on the above in your issue of August 29th, as I quite agree that it is one of the best asters. I have the taller form, which is very beautiful provided it is allowed to grow naturally without being tied up at all. It starts flowering about mid-July and lasts until October in full beauty. If lifted early in spring, just as it starts into growth, broken up, potted in small pots and put into gentle heat, even the smallest pieces grow quite easily. A. Trikarti is now flowering with me; it has larger flowers than Thomsoni and is an excellent grower, but I so far do not think it will be as graceful or as light as the old Thomsoni —J. B.

SOUTH AFRICAN GLADIOLI.

SIR,—I have read with much interest the article on "South African Gladioli," in your issue for July 11th, and I am glad to see that your correspondent calls attention to the extraordinary beauty of these flowers. I note he remarks that bulbs of them are almost unobtainable, and I should be grateful if you would allow me to state that I am collecting these and growing them from seed, partly with the idea of sending the bulbs to England, also to help to prevent their extermination by ruthless collectors. I have three varieties of the Painted Ladies found on the mountains in this district, one is particularly beautiful, having large creamy flowers suffused with pink on the outer side of the upper perianth segments, with the usual carmine markings on the lower segments, the blue anthers giving a perfect finish. Now in bloom are the "Pypjes," G. recurvus, very delicate flowers in every shade of blue, lilac, yellow and all sweetly scented. Later will come the "vlei Afrikanders," with large brown blooms. Another is a transparent scarlet with the shape of a primulinus bloom. If any of your readers are interested in these I should be glad to hear from them. I note that your correspondent describes Babiana stricta var. rubro-cyanea, "upper half of the perianth brilliant blue and the lower half a rich crimson." I do not think this gives quite the right impression of this striking flower. The outer part of the perianth segments are a brilliant blue and the lower, or centre of the flower, is deep red.

I should like to tell you how much we appreciate THE GARDEN, though we garden so far from Chelsea. Its pages are eagerly scanned for the latest carnation news and anything which keeps us in touch with the Old Country.—K. C. STANFORD, *Bloem Erf, Stellenbosch, Cape Province.*

DESTROYING SLUGS.

SIR,—There have been several articles appearing in THE GARDEN recently dealing with the slug trouble, and various remedies have been suggested, yet no mention has been made of Kainit. As I have benefited so much through using it, I should like to advise others to give it a trial. I got the advice fifteen years ago, after having tried for three years previously to deal with the trouble, yet without success.

The instructions given were to sprinkle the ground with Kainit in the month of November of each year, yet, although to the best of my recollection it has not been applied here more than six times in those fifteen years it has apparently been sufficient.

This spring when neighbours were complaining of the damage done by slugs, my gardener said he was unaware of any harm having been done in the vegetable garden, and in this I could support him, as it was so apparent.

I cannot give the quantity in ounces to apply, but it may be scattered as a farmer sows corn, broadcast, only rather more generously. By applying the Kainit in November the winter rains dissolve the salt and it then seems to find its way to the hidden slugs.—"PERTH."

SIR,—I was much interested in "W. J. G. F.'s" remarks on page 466, which appear to be a very simple remedy which most of us can adopt—and who is not troubled with slugs? We all know how fond they are of the young basal shoots of delphiniums, lapagerias and even clematis which happen to be on their roots, and it is in connection with quite young plants of the former and older ones of the two latter that these remarks are penned. Neither lime nor soot deters them from destroying these succulent shoots immediately they appear above the soil, and I have for some years used glass jam jars by carefully knocking out the bottom and then placing over the said shoots as soon as ever they are seen pushing through the soil. This simple precaution baffles the slugs; they cannot crawl up the jar. As soon as these shoots are out of danger the glass can be broken and taken away. They are specially useful for seedling delphiniums or tiny offshoots of a special variety one wishes to increase, and would be of value on many a rockery plant which depend upon such succulent growths for the season's display.—J. MAYNE.

AN ABNORMAL FLAG IRIS.

SIR,—In reply to B. Hanley's note in the issue dated August 29th, I grow a hundred kinds of flag iris and have only had one case similar to his, *viz.*, Iris Richard II. This very beautiful iris freaks with me every year; first it came double, another year with only two standards, often it opens in a torn condition, is a huge grower, but a shy bloomer, but when it blooms properly it is one of the most fascinating. I do not think Mr. Hanley's iris is Mrs. Reuthe, being too veined in the falls.—H. C., *Saxmundham.*

THE RURAL CRAFTSMAN.

SIR,—It may interest your readers to know that even in these days of machinery, the rural expert with the scythe can still be missed. I was talking recently with those responsible for the upkeep and care of the beautiful Cumberland turf bowling greens in this town —the annual tournament was then taking place —and I found they were lamenting the pending loss of their chief groundsman. It seems that Cumberland turf greens need skilful shaving with a scythe, just to leave green tips on the fibre mats of which they are composed, and that mere mowing with a lawn mower is ineffective for the purpose.

The difficulty, nowadays, is to secure really expert scythe wielders. So the rural craftsman is still valued, and as an old country resident I rejoice to hear it.—HENRY MORGAN, *Hastings.*

FORTUNE'S YELLOW ROSE.

SIR,—In THE GARDEN for August 15th, page 462, the first note on "Fortune's Yellow Rose" says, "It succeeds well in the South of England, but needs moisture and shelter." It has been growing on the south-west corner of this house for over twenty years on its own roots, and I never give it any more attention than to any other rose. It ramps up to the roof and flowers profusely every spring. The stem is over 11ins. round.—E. ALEXANDER.

AN ENQUIRY.

SIR,—There must be a number of readers like myself who are not so successful as they might be with Narcissus bulbocodium conspicuus. Perhaps some reader who has grown this gem to perfection might tell us about its likes and dislikes.—W. F. MCCASH, *Perth.*

CATALOGUES RECEIVED.

Messrs. D. Prior and Son, The Nurseries, Colchester.—An extensive list of roses, including many novelties. Herbaceous plants, carnations, and shrubs and trees are also referred to.

Messrs. Barr and Sons, King Street, Covent Garden, W.C.2.—Lists of flag irises, daffodils and hybrid nerines, and general bulb catalogue, the latter including all bulbous plants. Useful cultural hints are given throughout the pages, which offer a wide and extensive selection of plants suitable for all purposes.

Messrs. Chaplin Bros., Limited, Waltham Cross.—List of bulbs for autumn planting 1925; also a useful collection of roses, fruit trees, trees and shrubs, in a separate catalogue.

Messrs. W. Cutbush and Son (Limited), Barnet and Highgate, London.—List of bulbs and other forcing plants, with numerous illustrations.

Messrs. A. Frylink and Sons, Sassenheim, Holland.—List of bulbs, with numerous illustrations and copious culturdl notes.

Messrs. Ant. Roozen and Son, Overveen, Holland.—An extensive list of all bulbous plants which all enthusiasts should have.

OUTSIDE SEED BEDS

OWING to lack of space in the greenhouse, I was forced to sow a number of seeds outside which are usually grown under glass. By this I mean primulas, meconopsis and rhododendrons. This is by no means the first time that this has been done, for Mr. White at Sunningdale has grown rhododendrons successfully for many years from seed sown either out of doors or in unheated frames. On the other hand, few amateurs make a practice of this outside seed sowing, presumably from fear of the casualty list. One keen primulist who has no glasshouse has had to rely for years on plants raised by other people—an unnecessary expense. The results I have had might interest some readers of THE GARDEN.

It must be remembered that my garden is on the east coast of Scotland, where the drought this year lasted for about ten weeks; also, we are not in a neighbourhood where rhododendrons seed themselves. This also does not take into account scattered and self-sown seed of primulas in the wild garden, which is also satisfactory.

I began by double trenching two beds 6ft. by 3ft. 6ins. in the middle of a thin wood where there was plenty of light, but they were almost completely sheltered from the sun. The top spit was heaped on the side of the beds to make an added protection. The bottom spit was raked but not beaten down, and on the top of it was placed a 2in. layer of sieved leaf-mould 2 parts, coarse sand 1 part, loam 1 part. This made the level of the bed 8ins. below the top of the bank. This was done at the very end of April. It was well watered and left over night.

On the next day the seed was sown in plots, each plot being divided off by strips of bamboo. The only soil covering I gave them was a dusting of sand, which, I think, was a mistake; it should have been riddled leaf-soil and sand mixed. The beds were then covered with wire netting. The only attention they have had was twice weeding and a very occasional watering. Although fairly sheltered from the wind, additional shelter would probably have been an improvement, for, although the seeds have not blown away, a few of the rhododendron seeds may have shifted their quarters.

The results, so far, are as follows: Primula sikkimensis P. secundiflora and P. glycosma have germinated in bulk and are now about an inch high. Meconopsis Wallichii, M. rudis, M. simplicifolia and M. Prattii—all sown—have briered splendidly and are now strong, healthy plants about 2ins. high. M. Wallichii, always inclined to damp off, have come up like mustard and cress with no signs of damping off. About forty out of sixty rhododendrons have germinated, an exceedingly good percentage in four months, considering the dryness of the atmosphere and the short time since they were sown. Five of them have germinated in bulk, the rest just a sprinkling, but sufficient to give me a stock.

The birds showed great curiosity over these beds for the first week or two, but now they never go near them. I shall do no pricking off this year, with the possible exception of one primula and one meconopsis. For winter covering the only thing necessary is a layer of branches laid on the top of the wire netting—not a very laborious operation.

I see no reason to suppose that these seedlings will not survive the winter, for they are all of hardy species. The obvious disadvantages of this method of seed sowing are that you lose a year by sowing outside instead of inside, and that the seeds stand a greater chance of damage from natural causes, which means that it is safer to sow seeds inside if they are in small quantities. On the other hand, there are certain great advantages. Seedlings do not have to be handled so much as the damage from damping off is lessened, so they can be left longer in the seed-bed outside; and the seedlings are often hardier, as there is no shock to the seedling in transplanting it outside, which is often the case in an inclement season when taken from a house to a nursery or a bed outside. This method of outside sowing also does away with the large amount of space necessary for pans and boxes when seedlings are pricked off in a house. I have noticed that seedling rhododendrons which have been grown from seed sown outside spring away better from the ground: this is at least the case on the east coast of Scotland.

I am so well satisfied with this experiment, at any rate, that I am going to continue it next year with other seeds. No doubt there are many which are not suited to this outdoor treatment—among them all seeds which take a long time to germinate; but such shrubs as berberis and such trees as the birches, even in rare varieties, would probably be far less costly to raise and give little trouble or labour if sown in an outside seed-bed.

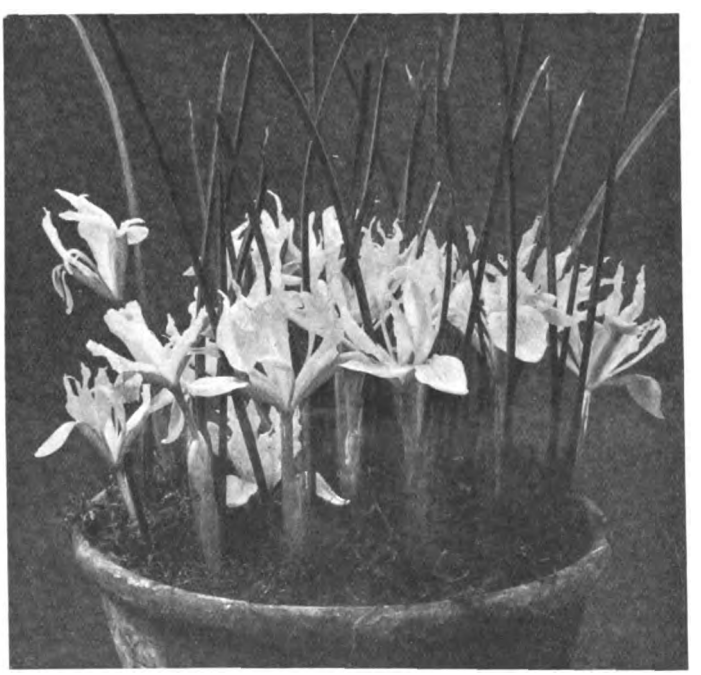
DWARF BULBS AND TUBERS for the COLD HOUSE

IF you are the owner of a cold greenhouse (by which is meant absolutely no heat at all), and are searching about for a means whereby this may be made beautiful during the early spring days, why not try specialising in dwarf bulbs? These are not only quite cheap to purchase, but very easy to grow and, by a judicious selection of varieties, you can be sure of a magnificent display of flowers from early February until the end of April.

Perhaps you are wondering why dwarf bulbs are especially mentioned. Well, the idea behind it is that they can be grown in shallow seed pans, about 6ins. in diameter. These hold a number of bulbs, can be packed close together during the growing period, and present a splendid appearance when covered with flowers, far better, indeed, than the deeper pots, although these can be used if there is a shortage of pans. Then, too, by confining the selection to bulbs that do not reach a higher stature than 1ft., one is sure of a much more varied and interesting display than where the more usual daffodils, hyacinths and tulips, bulk largely among the selection, and, last, but by no means least, the plants are not a one season investment. By taking a little care of them after flowering is over (and especially as you have not forced, but only anticipated), the same pans can be used again and again for several years, without even the trouble of re-potting. This is not at all an unduly optimistic statement, for I have tried this and found that, with a large number of species, the second and third and even fourth year of flowering have been no whit inferior to the first year they were grown.

To ensure this permanent use one must take reasonable care of them after flowering. They must not be left without due supplies of water, nor must one suddenly turn them out into the cold open air and leave them to fate without further thought. Careful hardening off is necessary, and then one must have a plunge bed where they can spend the summer and autumn before renewed growth takes place. A plunge bed consists of a thick bed of ashes, into which the pans can be sunk to the rims.

We have gone somewhat far, however, from present work, for the immediate job before us in that of potting the bulbs which we propose to grow. With so wide a range of plants, it will be obvious that different composts are essential and care must be taken, as far as possible, to provide the soil best suited to the species. The wee, miniature daffodils, for instance, are admirably suited by a mixture of peat and turfy loam and do not require sand at all. A similar mixture is admirable for many of the anemones, while the delightful little tulip species luxuriate in a compost of one third coarse gritty sand to two-thirds fibrous yellow loam. Muscari, alliums, scillas, fritillarias, etc., will all be found to thrive in a general soil, such as two parts of good loam to one each of leaf-mould and coarse sand. Perfectly clean, well drained pans are essential and these should be two-thirds filled with soil, then the bulbs arranged on this and the remainder of the pan filled up. Here is where the first use of our ash bed comes in, for there can be no better place in which the plants should make their first roots. Plunge level with the rims, then sift a further 3ins. or 4ins. of ash over the surface so that they are completely buried and leave them here for three months. After that you may lift them and bring into the cold greenhouse.



A PAN OF THE GRACEFUL IRIS RETICULATA.

Having thus briefly outlined general culture, let us turn to the material available for carrying out such an idea. At the outset we spoke of economy, so that only those of moderate price will be dealt with, others can be added in future years. Very like the autumn colchicums, Bulbocodium vernum, with its bright purple flowers, is splendid in February and March and has a very distinctive appearance from the more ordinary crocus, of which it is a fitting companion. The crocuses themselves, of course, are ideal for our purpose and provide a very large range of delightful shades, varying from the deepest gold to the softest mauve and from deep purple violet to the purest virgin white.

Among the earliest flowers that give you a foretaste of the larger spring that is preparing out of doors is the chionodoxa, a well appreciated gem in purest blue and very easy to grow. The white form of this, though lacking the glorious colouring, is another splendid flower, and both of them are conspicuously long lived under good culture. Anemone apennina is another successful plant that will give a wealth of large daisy-like, sky blue flowers thrown well above attractive, fernlike foliage. A. stellata, too, is another good variety to grow, but, with this, it is far better to rely upon new tubers annually. The American varieties of the dog's tooth violets make fine plants when grown in the peat and loam mixture, and the varieties grandiflorum and revolutum merit special praise, for, in addition to the charming effect of the many flowered spikes which push up from the centre, the foliage in both cases is broad and handsome and beautifully mottled with white. The common snake's-head fritillary forms a very attractive feature, but far more striking and less ordinary is the marvellously chequered F. recurva, in which the flowers are scarlet and yellow and very dwarf indeed. Another, though less brilliant, fritillaria is citrina, which is quite distinct from either of the above, with long drooping greenish yellow bells. Some of the hardy cyclamen should not be missed for spring flowering: among them are C. Coum, which has brilliant crimson flowers and Coum album, in pure white. Both of these are February blooming and therefore you secure far more perfect examples where grown under the protection of an unheated house. C. ibericum which follows closely upon the Coum varieties, does not exceed 3ins. in height, and produces a profusion of crimson flowers with purplish black blotches at the base. The variety of this, known as Atkinsoni, is even more striking, with pure white flowers, conspicuously blotched with carmine at the base. These four plants are gems and flourish in fibrous peaty loam, to which a generous addition of lime rubble has been made. Snowdrops make lovely pans and, if the soil is to their liking, often do well for several successive seasons, though, at other times, new bulbs have to be procured annually.

Dwarf iris offer a wide field for experiment, and an almost inexhaustible range of varieties may be procured, although some of the rarer forms are expensive. I. Histrio flowers very early with beautiful blue flowers and, like the following species, should be potted as early as possible, in light soil. I. reticulata appeals upon many grounds. Not only do the flowers come very early, but their deep violet-purple colour with orange blotches is certain to please. The dwarf Narcissus bulbocodium, the yellow Hoop Petticoat, may well be grown; the cup of this is

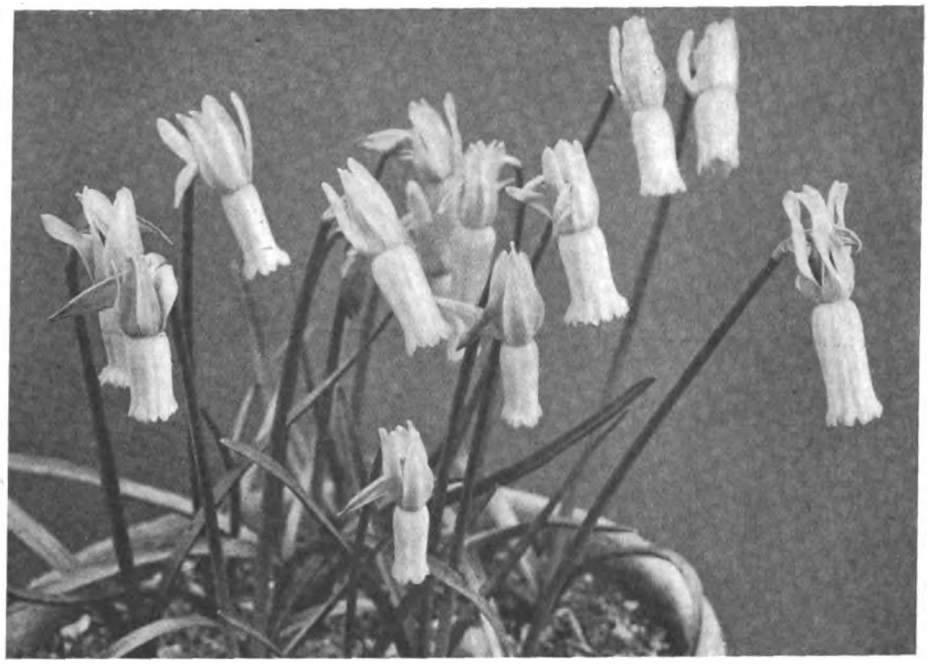
Digitized by Google

greatly enlarged and drawn out into a large frilled resemblance to an accordion-pleated petticoat. N. cyclamineus is perfectly distinct from this, a wee trumpet daffodil with reflexing perianth, only 3ins. high. N. triandrus—Angel's Tears—fully bears out its quaint poetic name, with its diminutive stature and cyclamen-like white petals, and makes a pretty little pan.

One of the best of all bulbous rooted plants for our purpose is Milla uniflora, a plant that abounds in desirable qualities. Not only does it bloom early and profusely, but the blossoms are of good size and delicately perfumed, and, last, but by no means least, the bulbs do not rest content with flowering once, but throw up further buds in succession, so that they remain decorative for an unusually long time. No wonder that this is called the Spring Star Flower, for its lovely white blossoms are exactly star-shaped in form and, whether the pure white variety be grown or its equally beautiful pale violet form, violacea, you will have superb pans of flower and foliage that last for many years.

And now to close an already extended selection upon a brilliant colour note, let us turn our attention to the tulip species. Some of these, it is true, are high in price and difficult to obtain, but there are plenty of others which are no less brilliant or beautiful and which are within the reach of a very modest purse. Greigii, for example, cannot be said to lack brilliance in its vivid scarlet, while its quaintly mottled leaves are an added attraction. T. persica is quite different again, a very dwarf grower, blessed by the unusual gift of fragrance and opening its flowers wide into little stars of glorious buttercup yellow.

H. W. CANNING-WRIGHT.



NARCISSUS CYCLAMINEUS WITH REFLEXED PERIANTH.

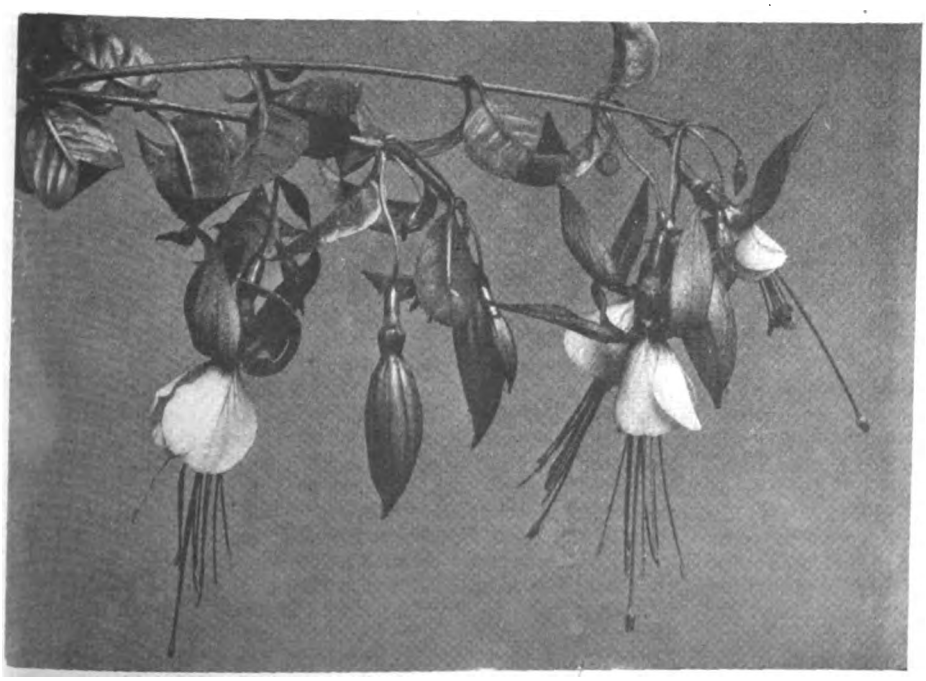
A PLEA FOR THE FUCHSIA

WHY is it that more fuchsias are not seen in our gardens and greenhouses to-day? *Autres temps, autres mœurs*, I suppose. Yet it is not difficult to imagine what an astounding flower the fuchsia must have appeared to those who saw it for the first time on its introduction from South America just about a hundred years ago. The centenary of the introduction of well known flowers might well be celebrated by special shows in much the same way as benzine and the railways are being commemorated this year. The fuchsia gets its name, which, by the way, is nearly always mispronounced, from a certain Dr. Leonhard Fuchs. He was a Professor of Medicine in the University of Tübingen in the year 1535, but took up the study of botany, and can be regarded as one of the fathers of this science. It was he who laid the foundations of botanical nomenclature as we know it to-day.

Most of the distinct species of fuchsia of which Robinson includes some seven in his "Flower Garden," are derived from South America, particularly from Chili, though a few come from New Zealand. Burbidge in his exceedingly interesting, if somewhat out of date, book entitled "The Propagation and Improvement of Cultivated Plants," tells us how in 1876 good fuchsia seed saved from fine varieties was worth some £50 per ounce. To-day it is possible to purchase a packet of mixed hybrid seed for a shilling or two.

For amateurs, and more especially for the impatient variety, there is no plant like the fuchsia. Seed sown in the autumn will produce plants to flower the following summer. Cuttings root with amazing facility and grow so rapidly that the resultant small plants will flower a few months later, though it is as well not to allow them to do so till they have attained a fair size. Fuchsias are also admirably adapted to the exercise of the amateur's skill as a hybridist, for the different varieties are easily crossed and produce a good quantity of seed, which for the most part will be found to be fertile. The seed obtained from hybrids, too, is fertile and accounts for the great number of varieties which have been produced. In fact, this is so much the case that it is positively rare to find a pure species.

The amateur can also get a good deal of amusement making standard fuchsias so that the pendent blossoms may be seen to



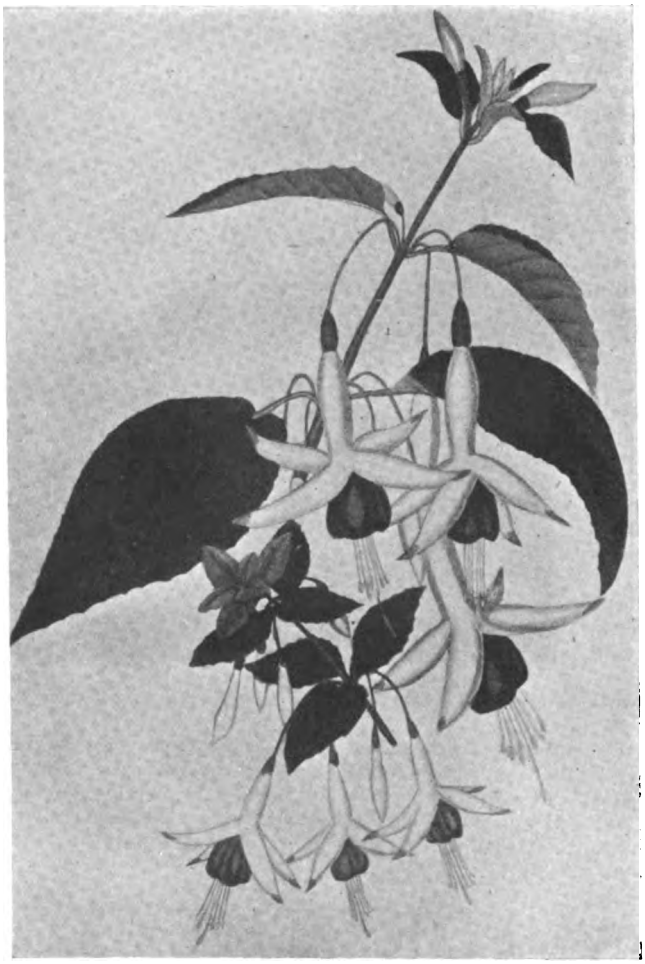
FUCHSIA DELIGHT, A GOOD OUTDOOR VARIETY.

Digitized by Google

greater advantage. This is very easily done by rubbing off all side shoots as they appear, and only allowing growth at the end of the stem. This soon becomes woody and can be kept straight by tying it to a stout bamboo at frequent intervals. The pruning knife must also be fearlessly used with an eye to shape. In this way a mop is soon formed at the end of the woody stem. A small country child seeing one of these in my garden for the first time was heard to exclaim, " Oh, look at this Christmas tree with the presents hanging from it." A very apt description. Such standard fuchsias, though they require to be taken in during the winter, do not require pampering or coddling; they can then be plunged in their pots during the summer months in some bed set apart for bedding-out plants, if such can still be found.

It is almost hopeless to try to describe the endless varieties of fuchsia flowers, from the tiny blooms of the common outdoor kinds to great big ones in the glass-house. All are brilliantly coloured; in fact, the fuchsia has given its name to one of the best known of the coal tar dyes used as a stain in bacteriological work. Fuchsia flowers may be divided very roughly into two main groups, in one of which the bud has an elongated shape, the other being almost globular. To the former class belong all the single or nearly single varieties; to the latter those with many frills to their petticoats. Sometimes the sepals and the petals blend beautifully together. Sometimes they contrast vividly, as in the well known double variety with cherry red coloured sepals and rich violet petals. Then we have those with white sepals and either dark purple, pink or red petals. The first fuchsia with white sepals, Venus Victrix, seems to have caused great excitement as long ago as 1842, when it was sent out by the Rev. S. Marriott of Horsemonden, Kent. A plant cost 21s. in those days, and it was described in glowing terms by the firm which was responsible for its sale.

For those interested in what may be called plant curiosities the fuchsia family provides a dainty little trailing plant, which at first sight one would not connect with this family at all. This is F. procumbens, which comes to us from New Zealand. With small leaves, like a campanula, this little plant grows over the edge of the pot and puts out charming little flowers which apparently consist of four sepals forming a beautifully shaped yellowish tube. Where the points of these sepals are reflexed they are at first bright green tipped with brown. The characteristic prominent stamens are red with mauve anthers and all the more noticeable because the flowers do not exhibit the usual pendent habit of the family to which they belong. Later, fleshy fruits are formed which, when ripe, are of an orange hue.



TWO OLD FUCHSIAS: VENUS VICTRIX (*top*) ENCHANTRESS (*bottom*).

It is very fascinating to watch a fuchsia bud opening. The four sepals seem to be held at their tips by some invisible hand, while they split along their length, giving one a glimpse of the hidden beauty so soon to be revealed. Then the pressure becomes too great and the invisible fingers have to give way. The four elegantly shaped sepals bend back, often slowly curling in on themselves like a Turk's cap. The flower also owes much of its beauty to the long pistil and the delicate pendent stamens just above it.

Of outdoor fuchsias there are several quite hardy kinds which we can grow in our gardens if we afford them a little protection at their roots in winter. Of course, we cannot hope for the same luxuriance of growth as the fuchsias of Devon and Cornwall and some parts of Wales near the sea, where they grow into great bushes. In Devon they are often used for hedges, as in the famous fuchsia valley leading down to the little bay of Lee, near Ilfracombe. In Wales they often grow up the sides of the white cottages, against which their little bright red flowers show up quite gaudily. In less favoured localities these little outdoor varieties can be grown like herbaceous flowers. Cut down by the frosts of autumn days, the roots protected with a few ashes or some similar material during the winter, they will shoot again with the advent of warmer days. I have seen a fuchsia hedge surrounding a gardener's cottage on an estate within twenty miles of London; the shears were freely used and the hedge kept trim. Each year it bloomed in its due season.

Let us, therefore, reinstate the fuchsia on its Early Victorian pedestal, from which its flowers may be seen to advantage.

EDWARD CAHEN.

CRASSULAS—INTERESTING SUCCULENTS

BY DR. R. LLOYD PRAEGER.

THE difficulty about practically all the crassulaceæ is that, while the more typical species which make up the bulk of each genus are quite distinct and easily placed, the genera tend to run into each other along their borders. Almost every one of the group contains species which are intermediate in character between two genera, and are forced to play the part of shuttlecocks where the battledores are the conceptions of the rival genera in the minds of different botanists. To the botanist such intermediate types are interesting, as affording clues to the evolution of the groups, and he is at pains to study all their characters, and to place them in that genus to which they seem to him to have most affinity—and on this point different workers may well arrive at different conclusions. The horticulturist, on the other hand, is generally content to grow his plants for their beauty or interest.

However, there are plenty of crassulas left, and if none has so large and brilliant blossoms as the former C. coccinea, they are a quaint and interesting race, mostly sub-shrubby and of a characteristic fleshiness—whence they derive their name, for *crassula* may be translated as " little fatty." The leaves, stiffly set in opposite pairs, each pair at right angles to the pair below, are often of striking form or colour, and frequently are joined together at their bases, so as to enclose the stem in a quaint little platform of succulent tissue. The flowers are mostly of secondary importance, being almost always quite small, and white or red in tint. But the whole

Digitized by Google

aspect of these plants is generally attractive; they rightly are well represented in the Succulent House of most botanic gardens, and are frequent in private collections.

When "Index Kewensis" was published (1895), about 200 species of crassula were included in it. In the five supplements which have appeared since, nearly 200 more are quoted, so that if we make a further addition for the new species of the last ten years, and an allowance on the other side for synonyms and errors, the genus as at present known appears to number nearly 400 species. This great group is practically confined to South Africa, for outside that area we find only a few species recorded from Madagascar and Abyssinia. C. indica, for many years regarded as the sole Asiatic representative, is now considered to have closer affinities with sedum than with crassula. But this exclusively South African distribution only holds if we exclude from the genus the little tillæas and bulliardas, often looked upon as crassulas; these have an almost world-wide range. While there are a few annual and a few creeping species of crassula, the great majority are sub-shrubby, forming bushes which vary from three or four inches to three or four yards in height. The succulence of leaf and stem which runs through all the crassulaceæ is fully developed in the crassulas, and an old plant of one of the large species is as thick-stemmed and gnarled as one of the euphorbias or cacti of the desert.

Coming as they do from South Africa, it is too much to hope that they will be hardy in our climate; but there is one species, C. sarcocaulis, which makes an excellent rock garden plant in all the milder areas—a neat, much branched little shrub, half a foot high, with glaucous leaves and innumerable pink flowers in dense clusters. If we are to make the best of the others, they should be put out for the summer, since then they lose the laxness and monotonous greenness that succulents tend to assume in greenhouses in our unsuitable climate, and put on some of their characteristic variety of shape and colour.

The crassulas offer no difficulty in cultivation, needing only a very porous soil, with plenty of brick chips or lime rubbish, and coming easily from seed or cuttings. The following is a selection of the species which are in cultivation in England:

C. ALBIFLORA.—One of the best for bloom, with large, flattish panicles of white flowers.

C. ARBORESCENS.—Very striking, with broadly spathulate leaves with green dots and red margins, and rather large, pink flowers.

C. BRACHYANTHA.—A pretty, small, compact plant, with very hairy leaves.

C. CENTAUROIDES.—A rather graceful branched plant, with pink flowers.

C. COLUMNARIS.—Very curious, resembling a large pebble, with a rosette of broad, incurved leaves; before flowering it shoots up into a leafy stem.

C. CONJUNCTA.—Rather tall, erect, with perfoliate, glaucous leaves and white flowers.

C. COOPERI.—A small, tufted plant, with pretty leaves, mottled with red.

C. CORDATA.—Curious and interesting, with stalked, heart-shaped leaves.

C. DECEPTOR.—A curious species, resembling a stone. Leaves overlapping, glaucous, red margined.

C. DEJECTA.—A small, sprawling plant, with flat panicles of white flowers.

C. FALCATA.—One of the largest species, with stiff, solid stems, 1yd. up to 2yds. high, clothed with large twisted leaves set vertically, and yellow flowers.

C. HEMISPHÆRICA.—Forms a low rosette of broad, reflexed, densely overlapping leaves.

C. IMPRESSA.—A small, lowly plant, with leaves marbled on face and red on back, and pink flowers. It takes its name from the curious depressions or pits which cover the face of the leaves, which are also present in some other species, such as Bolusii, Cooperi and Schmidtii.

C. LACTEA.—Large and striking, with spathulate-rhomboid leaves and large cymes of white flowers.

C. LYCOPODIOIDES.—Well deserves its name, as it is quite like a club-moss, or the flower spike of the rat's-tail, Plantago major. The flowers are extremely minute, in the axils of the tiny leaves.

C. MONTICOLA.—Neat, plump, erect, with flat panicles of white bloom.

C. MULTICAVA.—A large bold plant, with ovate, stalked leaves and pretty small pink flowers in panicles.

C. NAMAQUENSIS.—Interesting, rather like deceptrix.

C. NUDICAULIS.—A large, striking species, with a very short stem.

C. ODORATA.—Very tall and solid, resembling falcata.

C. ORBICULARIS.—Quaint, forming a stemless rosette which produces short runners.

C. OBVALLATA.—A stocky, solid dwarf species, with tongue-shaped leaves.

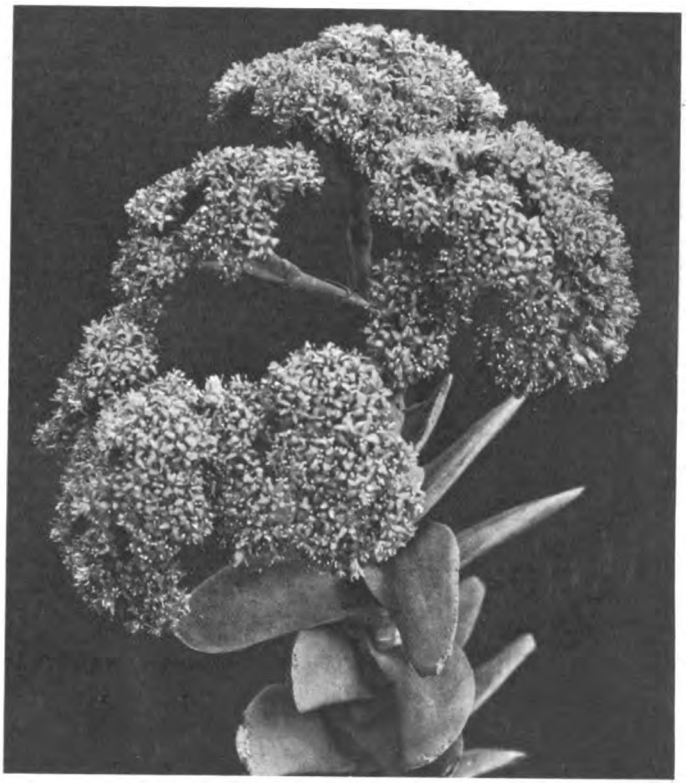
C. PALLIDA.—A massive plant with erect stems a yard high and pointed leaves 8ins. long. There is a good hybrid between this and Rochea jasminea.

C. PERFOLIATA.—Another large, striking plant.

C. PERFORATA.—Stems slender, erect, stiff. Leaves ovate, acute, green, joined together in pairs. A neat little plant.

C. PERFOSSA.—A handsome, dense-leaved, tall species.

C. PORTULACEA.—Forms eventually a large bush with a trunk as thick as one's leg. Much branched, with spathulate dark green, red-edged leaves.



THE YELLOW-FLOWERED CRASSULA FALCATA.

C. PSEUDOLYCOPODIOIDES.—A very interesting plant, in spite of its nine-syllabled name. Like lycopodioides, but leaves longer, etc.

C. PYRAMIDALIS.—Most distinct and effective—a dark green, square column of densely overlapping leaves, topped with a round head of white flowers.

C. QUADRIFIDA.—Most like perfoliata.

C. ROSULARIS.—Flat-growing, rather large, with upright, compound racemes of bloom.

C. SCALARIS.—Of remarkable appearance; grows prostrate with dense fleshy leaves, all erect and parallel.

C. SCHMIDTII.—Comes near impressa.

C. SPATHULATA.—Slender, leaves stalked, with a pretty lax inflorescence of pink blossoms.

C. TETRAGONA.—With erect stems bearing green, pointed leaves, recalling Sedum altissimum.

C. TURRITA.—A very queer plant, forming a little leafy pyramid with inflorescence like a milfoil.

If we include the rocheas with the crassulas, we add several species which greatly enrich the genus. The fine R. coccinea has already been mentioned. R. jasminea has very long, tubular white flowers. R. odoratissima is very fragrant, which few of the crassulas are; a stiff, erect plant with white flowers in rather dense heads. R. versicolor is rather like a pinkish R. coccinea.

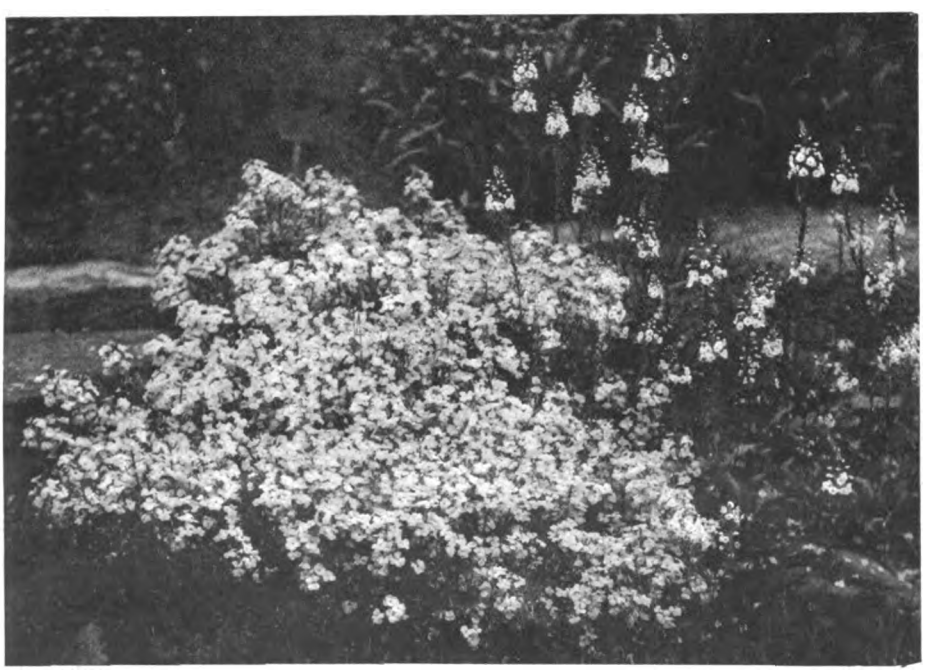
NOTES OF THE WEEK

DIPSACUS: THE WILD TEASEL.

COMPARATIVELY few gardeners grow dipsacuses, or, indeed, know anything about them, unless it is to associate them with weeds and other interlopers, yet it has to be said of them, given the right environment, they have a beauty of their own and are worthy of cultivation. Demand creates supply, but in the case of the plant under notice it is rare that one observes any offered for sale, and you may scan seed catagloues in vain to secure this wilding. Certain writers give them short shrift, content to dismiss them as being of the annual or biennial order, coarse in growth, being found in woodlands and stony places, but have no word of praise for them for the garden. Last autumn, when in the garden of a friend, I came across a colony of dipsacuses which had sprung up on a little promontory in his rock garden. Probably the seed had been carried there in a fresh deposit of soil. It was the tall variety D. laciniatus, with cut foliage, and the stalks produced from the centre of the plants were full of thistle-like heads, then greenish purple in colour and very attractive. As the season advances the bright tints leave them a dull greyish brown, and they are found useful for winter decoration along with echinops, eryngiums, statice, etc. A few months ago I was in a village and happened to find my way off the beaten track to an old stone quarry long since left to itself, judging by the plants about it and the wildfowl which had found a sanctuary among the reeds in pools, the result of excavating generations ago. There I found young teasels springing up in all directions, as they had done year after year. The best plants appeared to be those growing between the fissures of sandstone "where there was not much earth." Carefully lifting some of the smallest, I brought them home and quartered them in my little rock garden in somewhat similar surroundings, and, notwithstanding long weeks of drought, they are holding their own. Seed is easily obtained by shaking the heads of dipsacuses after they are dry and sowing them out of doors in almost any kind of soil in May, treating the plants as biennials, much in the same way as one does a Canterbury bell. One cannot introduce them in a border very well, but there are places in a garden where their presence would be appreciated, particularly by those who have flowers for winter decoration in view. I am informed that before the introduction of machinery for brushing up velvet that heads of teasels were used, and at one time were largely grown for this specific purpose.—W. LINDERS LEA.

CHEIRANTHUS ALPINUS.

FOR spring bedding one frequently hears the praises of Cheiranthus Allionii sounded, because of the rich orange colour of the flowers, but seldom indeed is any mention made of C. alpinus, the lemon yellow blooming sort which makes a capital tenant for a rock or wall garden. I have looked through lists to discover where seed can be purchased but have not yet come across it. Last year in a packet of seed of C. Allionii three or four plants of alpinus came up. This variety is more compact than Allionii, and I should describe the colour of the flowers when they first open as a greeny yellow, fading to a lemon yellow, extremely pretty in May. There used to be grown, years ago, if I remember rightly, a double form of C. alpinus under the name of Harpur Crewe. It was very attractive in the border in the early part of June. I am of opinion that it was perpetuated from cuttings mainly, and if this is so, it will probably account for its disappearance, most double flowers yielding little, if any, seed. I wonder if any reader can throw any light on C. alpinus or C. Harpur Crewe.—W. F.



THE LEMON-YELLOW WALLFLOWER C. ALPINUS TOGETHER WITH VERONICA GENTIANOIDES.

A NOTE ON POTENTILLA FRUTICOSA.

DR. PRAEGER, in one of his articles in THE GARDEN called Potentilla fruticosa "that kaleidoscopic 'typus polymorphus,'" and with every reason. It is really high time that someone in authority settled the type and various forms of this charming, but bewildering plant. Mr. Bean in his "Trees and Shrubs," mentions the type and eight varieties; several others have been added since his book came out. Although this invaluable late summer-flowering shrub is rapidly becoming more popular, yet many of them are sold without varietal names. Here is surely a case where proper distinction by varieties would be of great assistance to the gardener, for the varieties vary considerably and some are far better than others. They can roughly be divided into three groups: the white-flowered forms, the dwarf, and the larger yellows. By far the commonest and the best of the whites is var. Veitchii, with greyish-green leaves which are covered with very fine hairs. The variety Vilmoriniana is far less common, although I have occasionally seen it grown as Veitchii. The leaves of Vilmoriniana are distinctly silvery and the flowers have a creamy tinge. Leucantha, I have never seen, to my knowledge, and, indeed, have never seen an adequate description of this variety. Could any reader supply the information?

Of dwarfs there are two, var. pyrenaica, of close habit and clear yellow flowers, and var. parviflora, one of Purdom's Chinese varieties. I have seen this quoted as being the same as Farrer's Kansu plant, No. 188, but that is not the case.

Now come the larger yellows, headed by the type which is still to be found wild in the British Isles. Even this varies considerably, but as a rule the leaves are larger and the flowers smaller than in the named varieties. Mr. Bean mentions two varieties, grandiflora and micrandra, which I have never seen to my knowledge. Var. ochroleuca is one of the commonest in gardens and is that which is usually sold as plain P. fruticosa, without any varietal name attached. The flowers are lemon yellow and the leaves are greyish-green.

Now comes the difficulty: Farrer's Kansu plants, which are rapidly spreading through the country. I have one of his original plants, under No. 188, which is particularly floriferous and is frequently in flower until late October. The flowers are not so large as in many forms and in colour are between buttercup and lemon-yellow. The leaves are quite silvery, but have only a few hairs. It is planted on the top of a dry bank and is about 4ft. high by 4ft. through. I have also two cuttings from another of his original plants at Ingleborough, which came out of the same seed pan as my large plant. These cuttings are now five years old and are entirely different from my original. They are more erect and not so bushy in habit. The leaves have no silver in them and the colour of the flowers is almost golden, it is so bright. These are infinitely better than my original plant and are about the finest P. fruticosa I have ever seen. What is this variety and if it has no name, will somebody kindly name it? There must be plenty of it about, for Farrer scattered it generously through the country.—E. H. M. C.

TWO VALUABLE AMARYLLIDACEOUS PLANTS FOR THE AMATEUR.

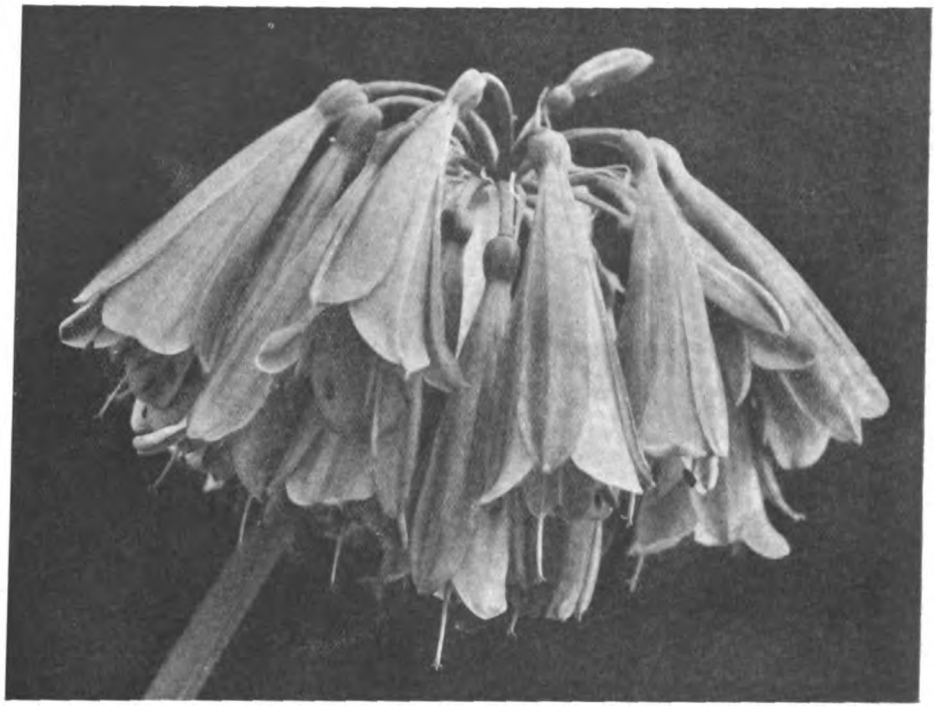
AMONG the amaryllidaceæ there is quite a number of popular plants with large and beautiful flowers, that can be successfully grown in the living-room of our ordinary houses. Clivias, for instance, make excellent house plants, and C. miniata, or Imantophyllum miniatum, is an old-fashioned plant, not only of the conservatories, but of the window in the living-room. A good many improved horticultural varieties of it have been raised within the last half of the past century, with larger and darker flowers than the type has.

Digitized by Google

Besides C. miniata from Natal, the genus is represented in our gardens by quite another type from the Cape Colony, C. nobilis, or I. Aitonii, of which the flowers are not erect but pendent and have a more narrowly funnel-shaped perianth. The illustration shows a form rather like the typical nobilis, but in reality a hybrid between that and the former species, of which, however, little, if any, influence can be observed. This hybrid, C. cyrtanthiflora, was raised about 1866 by Charles Raes, one of the head gardeners of Louis van Houtte, the then famous Belgian nurseryman. It was first pictured in the "Flore des Serres," plate 1877, in 1869-70, and the plant of which I took the photograph agrees well with van Houtte's illustration. The flowers have the same greenish tipped segments as C. nobilis. I do not know if this cross has been repeated; it would certainly be worth while to try it again to produce a form more similar to C. miniata, at least in the shape of the flower and its colour. As to the treatment, there is no difference between the two species of clivia. They have thick, fleshy roots and need rather large pots and a rather rich soil, but good drainage. During the winter the plants have to be kept dry and cool. Their flowering time is usually from April to June.

The Spider Lily, Hymenocallis speciosa, from the West Indies, is well known, too. Its flowers are of a rather curious shape, the perianth being salver-form with a narrow cylindrical tube and linear segments spreading like the filaments which are united below into a small toothed cup. The colour is snowy white, and the fragrance is sweet, like vanilla. The leaves are obovate-lanceolate and distinctly petioled. There is another type in the genus with sessile strap-shaped leaves, and somewhat different flowers with a larger cup and short and incurved free filaments. Of this group, sometimes called Ismene, H. calathina is the best known species, from Peru and Bolivia.

The treatment is about the same as that for clivias. They like a mixture of turfy or peaty loam with sand. The bulbs usually improve with age when carefully treated and re-potted. H. speciosa flowers in winter or spring, and can be grown successfully in any living-room suitable for plant cultivation.



THE HYBRID CLIVIA CYRTANTHIFLORA.

Unfortunately, most of the living-rooms of our modern houses are less suitable for plants than the less carefully equipped ones of our grand-parents. The atmosphere in our rooms is usually too dry and so is injurious to plant growth. The plants suffer more from too much heat and too dry air than from a lack of light. But, of course, any room where plants are to live should be well aired and full of light.—CAMILLO SCHNEIDER.

WEEPING TREES.

WEEPING trees, or trees with pendulous branches, have always a fascination for the ornamental gardener and the country possesses some fine specimens to-day as a result of the decorative efforts of a past generation. The amateur's garden is not altogether suited to the cultivation of such trees, except the smaller kinds; the large trees need more than actual growing space to be at their best. These who have large gardens have not the courage, very often, to spare the cash necessary nowadays for really good specimens, so that such trees are difficult to procure, nurserymen only growing what there is a demand for.

Weeping oak, ash, beech, birch, willow, elm and other kinds may be seen when motoring through the country, and perusal of books on trees shows that these weeping trees have been made use of during the last century or two—earlier records are not sufficient to tell whether or no they were popular before that. Of course, since most kinds are raised by grafting or budding or are obtained from one particular corner of the world, it would be folly to expect to find them common before the advent of easy transport. Records seem to show, to take one example, that the weeping ashes can all be traced to a common ancestor discovered in Cambridgeshire 200 years ago, yet now we have several varieties of weeping ash, with quite obvious differences.

Such pendulous trees are always elegant and attractive, but, I myself like the beeches best of them all. Still, I know of many fine elms of stupendous spread and live near an ash which hangs limp from a graft nearly 40ft. from the ground; the birch and the Babylonian willow also are graceful, and since the name "weeping" so fitly applies to all these it seems invidious to select one as of merit outstanding above all the others.—CLYDESDALE.

THE SPIDER LILY, HYMENOCALLIS SPECIOSA.

HERBACEOUS PHLOXES.

FEW plants present us with a more agreeable display of colour at this time of the year, than do the herbaceous phloxes. A good deal has been written from time to time on the value and beauty of these plants, but the fact still remains that these delightful flowers are not grown, or given, the attention they deserve.

Phloxes are fastidious as to soil and position, and the ideal necessities are not obtainable in every garden. They like a deep, rich, fairly substantial loam, but all soils can be improved upon by deep trenching

Digitized by Google

and at the same time working in some well decayed farmyard manure.

Phloxes prefer a semi-shady position where they get plenty of air and light, but are sufficiently protected from the direct rays of the sun during the hottest part of the day. Brilliant sunshine the whole day long will bleach the bright crimson and scarlet shades.

They also make a charming addition to the bog garden, where the position is moist, but not wet. Another pleasing effect is obtained by planting them in bold groups by the side of ponds and streams. An essential point in the cultivation of phloxes, either in beds or on the herbaceous border, is they should not be overcrowded or overgrown by other plants. They prefer plenty of room, otherwise they get weak and spindly, and in a good many cases develop disease.

Attention should also be given to staking, as the rough winds and heavy rains generally experienced during the flowering season, cause the flower stems to break off at the base if they are not supported. Staking should be done not later than May, so that the young growths can be tied up periodically. It is also advisable to thin out the growths, and only leave about five or eight, according to the size of the plants. This treatment will result in a more sturdy plant and finer flower heads than otherwise could be obtained had all the growths been allowed to develop.

There are two good methods of staking, one to stake each individual growth with a slender cane tip, or if this will take up too much time, to resort to the more general method of using three stouter canes placed around the plant, and loosely tie or sling each growth to them. To use one stake and tie the whole plant to it, produces a hideous effect, and it would be advisable rather to leave the plant to support itself. During the last few years the herbaceous phlox has been greatly improved upon.

A BORDER OF PHLOX LA NEIGE.

As the selection is such a large one, it is nearly impossible to detail a special list, as tastes differ, but to introduce a few of the best and most popular would probably be more useful. In making a selection of phloxes it is advisable to study the catalogue which gives you the most detailed account concerning colour of flowers and height of plant when full grown, as they vary in height from 2½ft. to 4ft., which is a considerable difference in grouping or in the herbaceous border.

P. Frau A. Buchner, P. Mia Ruys and P. La Neige are all good white forms. The first has distinct rose shaded buds, and a pink shade lingers in the petals of the flowers for a day or so after that they are pure white. Produced in fine heads, 3ft. high. The second has pure white flowers and is very free flowering, 2½ft.

There are several good pink and rose shades which include P. Baron von Heeckeren, with fine salmon pink flowers, 2½ft. P. Elizabeth Campbell, a popular plant, with charming pink flowers, with a white centre, 2½ft. P. Jules Sandeau, produces fine trusses of soft rose-pink flowers, 2½ft. P. Selma, another very popular pink form, which will grow to a height of 4ft. P. Baron van Dedem, is a brilliant orange scarlet and looks well planted with the satin pink Sidalcea Sussex Beauty. P. General von Heutsz, might be described as a cerise scarlet, with large trusses of flowers, 3ft. P. Homeland, a new variety with large brilliant orange-scarlet flowers, proves quite a charming addition, 3ft.

Among the blue shades, P. Antonin Mercie is one of the best, with soft lavender blue flowers, with a large white eye, which is very effective, 3ft. P. Iris is also another good blue or perhaps better described as a violet blue, 3½ft.

This selection is only a few and could be added to by a score of others, but it would be impossible, as I stated before, to determine the best varieties with such a riot of colour to choose from.—R. C. JOLIFFE.

CORRESPONDENCE

CANADIAN FLOWERS FOR OUR WOODLANDS.

SIR,—I have read with much interest Miss Jekyll's note on "White Flowers in the Woodland," published in THE GARDEN of August 8th, which has just reached me on tour. May I put in a plea for the use of Canadian flowers—white and coloured—in woodlands at home?

The wealth of the Canadian flora is not realised at home, nor do gardeners there know that most of the Eastern flowers from this country demand woodland and moisture, and that, if they were grown thus, satisfactory results could be obtained, in a certain number of cases, though I quite acknowledge that Canadian plants are by no means easy to "do" at home, owing to lack of snow in winter and the general dampness of the English climate. Still, there are some that might, with advantage, find a home in English woodland and water gardens, as I have found from experience, because in the four years of my life here I have sent a great number of species to my Essex garden and the gardener finds that they have thriven, and in some instances improved, with cultivation.

Of white woodland flowers from here that would flourish at home are the various sorts of trilliums and the "Mayflower" (Epigæa repens), though this is one of the difficult things to satisfy, as it needs shade, moisture, a mossy surface to root in and a liberal sprinkling of fir needles and rotted fir branches to give the soil the acidity it requires. But it well repays any care bestowed for it blooms early and is extremely fragrant. There are violets, too, ranging from white to mauve-blue and yellow. Among low-growing plants that would do well in England are the twinflower (Linnæa borealis), found in practically every woodland of the Dominion; Goldthread (Coptis trifolia); Mitchella repens; and creeping snowberry (Chiogenes hispidula), whose china white ovate berries are most attractive. This dainty plant will quickly clothe dead stumpsin a place where it is happy. Clintonia borealis, with its wide lily of the valley-like foliage and Clintonia uniflora are other gems, the former having bright blue berries on a long, upright stem. The dodecatheons, again, thrive in semi-shade and moisture, and are truly lovely when seen in masses, as one sees them out here. Chimaphila umbellata is charming, and has the advantage of being an evergreen; while the pyrola family should not be forgotten, though they are rather maddening plants to grow and still more so to try to lift.

For anybody who has the requisite shade and real wetness of soil, the lady's slippers are a delight, whether the showy spectabile, pubescens, acaule, montanum, or the frail little Calypso borealis, pogonias and Arethusa bulbosas; but these are among the "miffy" things which will, or will not, thrive according to their mood and need a good deal of care and attention.

Of ferns from here there is no end, the finest, of course, being Adiantum pedatum, with its shiny black stems and feathery fronds; while among taller-growing woodland plants the Actæas—rubra and alba—should be included, for the former has the most glowing mass of crimson berries and the latter a head of strange black and white berries that has earned it the name of "Doll's Eyes," and which nobody who sees it at Thorpe Hall fails to notice. Smilacina racemosa and a large variety of so-called Solomon's Seal are other plants that should be added to the list, as they have wonderful berries at this time of year and form graceful masses of foliage effect near water, and in shade. I have touched only on the woodland plants, but there are hundreds of others that thrive in the open spaces of the prairies, and yet more that nestle in the crevices of the Rocky and Selkirk Mountains; while, surprising as it seems to the English mind, there are several species of cacti to be found on the prairies! This in a land with a temperature that frequently drops to fifty below zero.—EVELYN BYNG OF VIMY, *on tour in Alberta*.

INCARVILLEA OLGÆ.

SIR,—Lest anyone should purchase Incarvillea Olgæ under the impression that it is as hardy and perennial as the handsome I. Delavayi and other well known species, it may be well to warn them against doing so. I. Olgæ—which, by the way, is sometimes called I. Koopmannii—is not hardy in our gardens, and in some can only be treated as a biennial. It grows about 3ft. high, and has fine, rather feathery foliage, and small, rose-coloured, trumpet-like blooms. It is pretty in its way, but its short life is much against its value in our climate, while its beauty is not so transcendent as to warrant its inclusion in our gardens, now that we have so many lovely plants of undoubted perennial nature.—S. A.

ROSE ON THE ITALIAN LAKES.

SIR,—With regard to the rose grown on the Italian lakes, concerning which there has been some discussion in THE GARDEN, it is not Fortune's Yellow, as several of your correspondents suggest. It is quite different both in growth and colour. Its history is as follows: About 1880 the late Mr. Henfrey of the Villa Clara, Baveno, saw it growing

Digitized by Google

in some nursery garden in England, and had it sent out to the Villa Clara. There it grew and flourished. The nurserymen at Pallanza had it, and from there, no doubt, it went to Como. I got some plants of it about 1900, and sent it home to Scotland, where I have it now. I also took some plants to Hyères, where it still grows. It is not quite hardy in our severe winters, but does well on a wall or house. It requires to be protected in winter here, but I have no doubt that in the south of England this would not be necessary. We call it the Baveno Rose.—DAVID W. SMYTHE, *Perth.*

A FINE BED OF ASTER THOMSONI IN A READER'S GARDEN.

FREESIAS.

SIR,—I do not agree with Mr. Van Tubergen's remarks anent the naming of Freesia Wistaria. I know it has nothing to do with wistaria botanically, but its colour is identically the same, and I think this gives a plain and accurate description as to the colour and is much more appropriate than naming after a person or giving it a name that has no connection with the flower, either in colour or in any other way. The reason for naming was this: On the occasion of its being put up for award I wanted a name for it. Mr. R. Wallace, Mr. H. Chapman and someone else were discussing it with me, when Mr. Wallace suddenly exclaimed, "There's the name," and pointed to a group in the R.H.S. Hall which contained some plants of Wistaria sinensis. On taking over a plant of the freesia it proved to be identically the same shade. Thus was it christened. Mr. Van Tubergen does not object to using the *English* name of a flower for some of his varieties, which have nothing—more or less—in common with each other than my "Wistaria" has to do with its Latin namesake.—G. H. DALRYMPLE.

ASTER THOMSONI.

SIR,—Having seen a paragraph in a recent number of THE GARDEN about Aster Thomsoni, I send you a photograph of our beds of it now in bloom. We found it here five years ago and have ever since regarded it as the easiest and most satisfactory thing we have. It requires no coddling or staking, blooms for two months or more, and is easily multiplied by division in March.—WINIFRED MACNABB, *Chepstow.*

THE UTILISATION OF GLASSHOUSES.

SIR,—With reference to the article on "The Utilisation of Glasshouses," on page 469 of your valuable journal: In defence of the "disgruntled gardener," let me say that not one of the cultures recommended by your contributor could be successfully treated in the greenhouses under my charge, for the simple reason that it would be quite impossible to maintain the necessary temperature to attain success. I have to be content if my beans realise 2s. per pound wholesale, and tomatoes 1s. It is quite impossible to have them ready when prices are better, as you will realise when I state the conditions. My best houses were erected by my late employer's grandfather, and as my employer died recently at the age of eighty-six, you will have some idea as to their condition. They are heated with flues, and the best we can do is to keep them frost-proof during frosty weather. I have a range heated with hot-water pipes, but here again, owing to lack of piping, I can only secure a temperature of 45–50° during frosty weather. Owing to my employer not seeing his way clear to have the roofs seen to as regards paint, glazing and puttying, I am now busy attending to this matter myself, and am now on my third hundredweight of putty and an even larger quantity of paint, in the effort to secure a more watertight condition of the roof, ready for the time when the houses are filled with chrysanthemums.

Let me say that the conditions here noted are general in all the big places in this district and should Mr. Wells be called in, in an advisory capacity, I trust he will be fair to the gardener, who is already working under such unfavourable conditions, and point out to the employers the sheer impossibility of producing such highly profitable crops as his article referred to would lead them to expect.—HEAD GARDENER, *Chelford.*

AN ENQUIRY.

SIR,—Some months ago, from one of your correspondents, I learned of an apparatus which automatically turned on at a certain temperature an electric heater and turned it off again on the temperature rising to normal. This seemed a very useful scheme for people with greenhouses who did not employ a full-time gardener, and I made enquiries of the electric light company here and find the apparatus can be obtained. It is in use for other purposes, but I have not been able to get into touch with anyone who has used it in a greenhouse, and before I order it I should like to consult someone who has had it in use for greenhouse purposes.

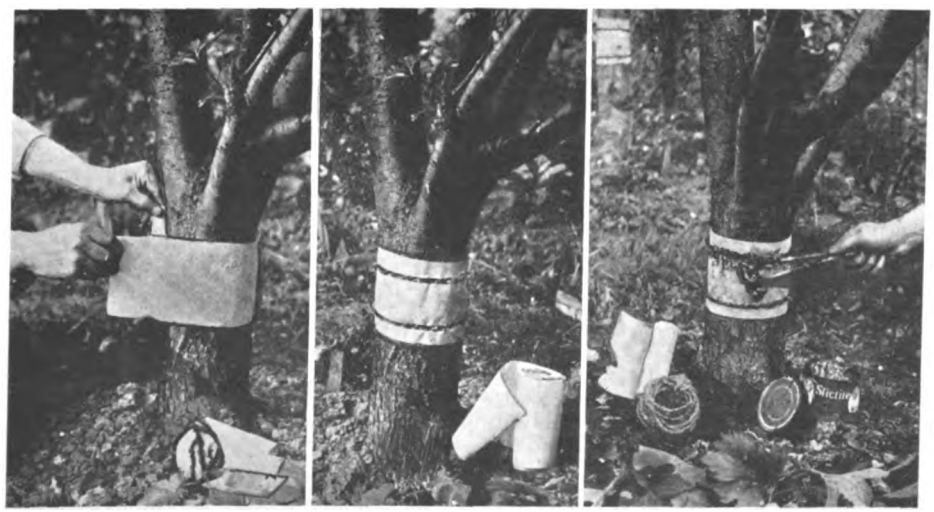
The points I should like practical experience upon are: (1) The size and strength of the lamp required for a 20ft. by 10ft. greenhouse; (2) the position in the house; and (3) generally, the efficacy of the apparatus.

It is possible that some of your readers may have installed one, and I should be grateful to be put in touch with him or them.—E. S., *Bromley, Kent.*

FRUIT TREE BANDING: A NECESSITY TO COMBAT THE WINTER MOTH

THE fruit grower who has had the mortification of seeing fruits of the greatest promise fall to the ground just before they attain eatable size, will appreciate the wisdom and value of protecting his fruit trees from the depredations of the insects that cause the trouble. One of the best means to combat these is by the application of sticky bands around the trunk or branches of the tree. This precaution, however, does not always have the desired effect, on account of indifferent placing of the trap upon the tree. The insects will take advantage of the smallest loophole or fault that enables them to evade the sticky substance and thus defeat the protective measures undertaken by the gardener. This should be remembered when the bands are being placed in position.

Tree banding consists of putting a width of grease-proof paper around the trunk of the tree and tying it there securely by means of string or specially made coir yarn. Upon this is spread a sticky substance, which effectually arrests the progress of any insect crawling up or down the tree and holds the depredator surely until it succumbs to the inevitable. In this manner many an



Place the band of grease-proof paper in position. *Tie the same top and bottom with string.* *Apply the sticky substance with an old knife.*

Digitized by Google

insect is caught and destroyed that would have been the cause of great destruction among the fruit next season.

One of the worst of fruit pests is the winter moth. The females of this moth, as well as those of the umber moth and March moth, possess no wings, and they crawl up the trunks of the trees in the autumn to lay their eggs on the branches. Should this be accomplished successfully, between two and three hundred caterpillars are let loose in the spring to do their deadly work upon fruit and foliage. It pays, therefore, to take strong measures to protect the trees from these enemies, and one of the most efficacious is tree-banding.

The best way to perform this operation is as follows :

Procure some good grease-proof paper ; this can be bought in rolls of suitable width. The object of the grease-proof paper is to keep the sticky compound from touching the bark of the tree, the paper presenting a surface through which grease or oil cannot penetrate. The paper is cut to the required length, using sufficient to meet around the trunk of the tree. It is then tied tightly round the tree, about an inch from the edges of the paper, top and bottom. The ties must be very tight, or insects will crawl underneath the paper and thus reach the branches.

The sticky compound, of course, will have been procured—there are several makes on the market—and it must be spread upon the paper about one-sixteenth of an inch thick, evenly and well distributed, so that no bare spot is left upon the paper. A wedge-shaped piece of wood, with a chisel-like edge is a good tool with which to do this, or the blade of an old dinner knife.

Tree banding should be performed near the end of September or beginning of October—certainly no later, as the moths begin their movements about this time and many may be caught on the freshly-applied substance ; indeed, quite an accumulation of insects will form on the band, for not only wingless moths, but those on the wing, with wasps, earwigs, woodlice and other creatures will find themselves trapped in this way. These accumulations must be periodically scraped away, or other insects will succeed in crawling over the dead bodies without becoming involved in the sticky mess.

The bands can remain on the trees all the year round, if desired, and on no account should they be removed until the end of March.

There is no particular place on which to put the bands. When convenient, they should be affixed round the trunk a foot or more from the ground, according to the height of the bare trunk. Should there be two or more main branches arising from or very near the ground, each one should receive a band ; and where there are stakes or other supports, these must be banded also, otherwise the insects will reach the upper branches by crawling up the stakes. This latter precaution should not be lost sight of. If possible, fences or walls upon which trees are trained could be smeared with a layer of the sticky substance a short distance from the surface of the soil, and certainly the supports of pergolas or archways on which trees are trained should receive attention by way of a sticky band. While putting up a fight against the foes of our fruit trees, we may just as well take every measure to make the victory more certain and the saving to our valued fruit a profitable and gratifying fact.

H. A. DAY.

GARDEN TECHNIQUE

Notes on the Technical Side of the Garden and on the Cultivation of Plants.

CULINARY PEAS.

THE culinary pea is one of the choicest vegetables grown and an early dish is always highly appreciated. This being so one tries slightly different methods, situations and varieties to attain this end. There are certainly many early varieties to pick and choose from, but so far we have not seen or grown one to surpass The Pilot as a first early pea ; one would naturally think that the extra adjective—first—should make a difference, and so it does in the case of The Pilot.

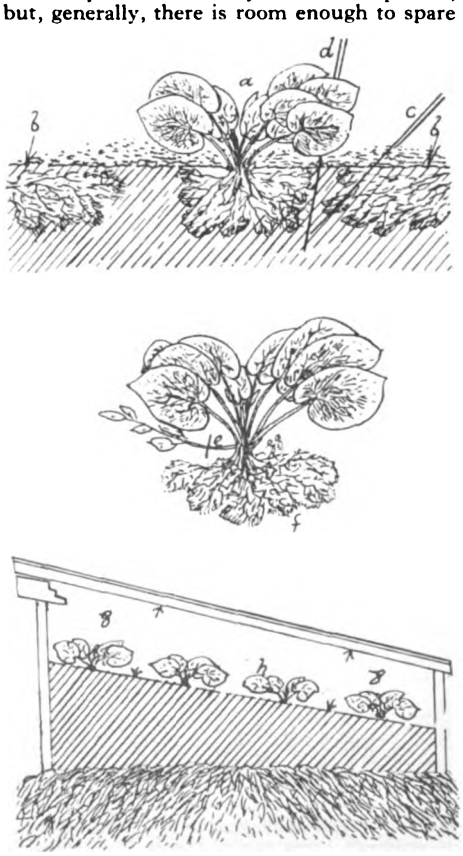
One season we grew as first earliest Laxtonian and Thomas Laxton ; the first named variety was sown on March 15th and Thomas Laxton on April 1st. Laxtonian is a dwarf growing pea and a splendid cropper, producing many large pods in pairs. Our first picking from this variety was made on July 14th. Now Thomas Laxton was sown fully a fortnight later—both kinds being grown side by side—yet a picking of peas was obtained on the same day, *e.g.*, July 14th. It should be pointed out, however, that the pods of Thomas Laxton are not so large as Laxtonian, nor are there such a number of pairs borne by the plants of this variety, yet apart from these differences Thomas Laxton is a fine cropper.

This year The Pilot and Peter Pan were sown on March 13th and although the former is a tall pea, it produced pods ready for picking on July 4th, fully a week in advance of the dwarf Peter Pan.

We have tried a comparatively new variety called Giant Stride, said to be " The largest-podded dwarf pea in the world " ; it is classed in the early section, so we had seed sown on the same day and on the same border as The Pilot and Peter Pan, and the pods were ready for picking on the same date as Peter Pan. The well known Gradus is classed as an early—yet not as a first early—but strange to say we sowed seed of it and The Pilot on April 13th and pods were ready for picking on both kinds about the middle of July.—D. A.

LIFTING AND PLANTING VIOLETS IN FRAMES.

THE fragrant violet is appreciated in every garden, and even in the smallest a few plants may be grown during the winter and spring months. A tiny frame can be placed in a backyard and soil only used for the plants ; but, generally, there is room enough to spare in the majority of our gardens for a hot-bed on which to place soil and frame. In every case, the present is a good time to lift and replant the violets, so that the plants will get well established before severe weather comes. Violet plants dislike cold draughts : in summer these predispose the plants to red spider ; and in winter they retard growth, root-action and flowering. Select a sunny position for the frame and one on a dry base. It is not absolutely necessary to have a hot-bed, but an old cucumber bed would be excellent, if available. Ordinary loam may be used, but such would be improved if some old potting soil and fibrous loam could be added. The plant, *a*, should be lifted by inserting the tool as shown at *d*, and not as shown at *c* ; then the roots will be lifted intact, and the roots of other plants, *b*, *b*, will be free from mutilation too. Cut off young runners, *e*, and spread out the roots, *f*, when planting. The plants, *g*, *g*, should be almost close enough to the glass to touch it. Place the violets, *h*, about 10ins. apart—double-flowered sorts 8ins.—water, and ventilate freely after the first fortnight. Plant firmly, but do not, at any time, tread upon the soil.



SWEET WILLIAMS.

SO long as there are gardens, this old time flower will survive. In fact, I believe it grows in favour as the time goes by. The newer types of self-colours of pink, scarlet fawn, etc., are all very beautiful, but the old-fashioned mixed types of our old English village gardens will never lose their popularity. Some three years ago my master took me over these gardens at Hurworth-on-Tees, and here, there and everywhere were plants of these old-fashioned flowers, all ready to be pulled up, but in going through them I found very many growths with a long, straggling stem, so I thought the best plan to save the type without much trouble would be to cut off the best growths and treat them as cuttings. This I did, prepared them, and inserted them in lines where I would like

Digitized by Google

them to make a mass effect, and by attention to essentials, the whole bed turned out a most successful experiment, and made a very effective display. I have already made another bed and the same success seems assured. I do not know if other readers of THE GARDEN have done the same thing, but anyone who has similar old, leggy plants with growths of cutting size, will find the plan a most satisfactory one in every way. Therefore, I pass it on.—VICTOR HUGO LUCAS, *The Manor Gardens, Hurworth-on-Tees, Darlington.*

MICHAELMAS DAISIES—THE ADVANTAGE OF FREQUENT DIVISION.

FEW perennials grow with greater exuberance, when planted in congenial soil, than starworts. In some instances rapid growth is their undoing, and flowers become puny and insignificant; worse than this, when planted in a border, they usurp space rightly belonging to other things. It is therefore, of the utmost importance, if one desires to maintain anything like order in the garden, to divide clumps every two years, and this may be done in late autumn, when weather serves, or early spring. Left alone, Michaelmas daisies soon make abnormal sized bushes, which, for a time may be permitted on the margin of a shrubbery where room is available, but in the garden they are apt to become something of a nuisance when other plants in their near proximity die off through the gross feeding of the asters.—CLAREMONT.

PLANTING OF TREES AND SHRUBS.

EVERY year large numbers of valuable trees and shrubs are lost through careless planting, some because the site is not properly prepared, and some the larger proportion, because the site has been prepared in quite the wrong position. This refers very largely to those subjects which are generally considered half-hardy and in some few cases tender.

As regards the actual preparation of sites I shall have little to say, except, perhaps, that it cannot be too strongly impressed upon intending planters that to dig a hole about the size and depth of the root of a plant is to court failure by the shortest route. Whatever the size of root, *i.e.*, of shrubs, trees, etc., it is imperative that the ground be broken thoroughly to a depth of 2ft. to 3ft., even if there is only a thin layer of soil overlying rock, chalk or clay, break it up, tear it out, and then, *when it is out*, break up the bottom another foot or so, leaving the loose stone, etc., to form drainage below the good soil which is now added; the importance of this I will explain later on.

Much has been written on planting, but, nearly always, something is omitted. Some important point, often the position. It is on this point I wish to dwell.

To begin with, I will select two prominent members of the order compositæ, olearia and senecio, shrubby varieties. These both come from countries where they get, broadly speaking, plenty of moisture in the season of active growth, but excellent drainage, and mostly dry conditions during their dormant season. Both groups of plants are considered more or less tender, and here lies my point: the tenderness or hardiness of these particular plants rests very largely indeed with the planter.

Leaving out of the question Olearia Haasti and O. macrodonta, the tendency of the average person is to coddle them; he or she seeks shelter for them, often at the expense of position. Shelter is not necessary for most of them, therefore do not plant them in those little nooks in front of the shrubbery border where often they get little sun, far too much winter moisture and no wind; how nice and warm they are, but, alas! how fatal to their well-being.

No, instead of this, select the most open and, above all, the highest and consequently best drained positions that can be found. Plant them in such positions; they are both sun and wind lovers and the majority will stand the very roughest gales; the leaves and wood get hard and ripened, growth is checked early in autumn and has ample time to fortify itself against winter weather. A dry root run in winter and a few degrees of frost does not touch them; they are hardy!

But what a different picture when planted in low, moist ground. They fade away, they become tender, and the fault is the planters.

In this note I do not intend to give a long list of varieties, but in conclusion I will give the names of a few other groups to which similar conditions apply. Notably *Leguminosæ:* adenocarpus, the less hardy genistas, erinacea, ononis, medicago, anthyllis, indigofera, carmichaelia, notospartium, astragalus, desmodium. *Fagaceæ:* nothofagus, not all. *Compositæ:* microglossa, helichrysum, cassinia. *Myrtaceæ:* some varieties of eucalyptus, leptospermums. *Chenopodiaceæ:* atriplex, eurotia, camphorosma. *Labiatæ:* lavendula, elsholtzia, perowskia, phlomis, teucrium.

This list could be considerably lengthened, but I have mentioned enough to show that it is not altogether the supposed hardiness or otherwise of any particular plant which counts so much as the position in which it is planted.

To mention a case, on this estate, which is very large and affords every position for which one could wish, three plants of Teucrium fruticans were planted, one on high ground (very exposed position), one on slope, where ground received much water draining from above, and the third plant almost at marsh level and well protected in all ways.

Last winter decided their fate as follows. Plant on high ground grown tremendously, hard and stocky; plant on slope just held its own; plant on marsh level, dead by midwinter. It began to droop with advent of slight frost and much rain. One other point and an important one with the subject under review, always plant in spring, neither early nor late.—JOHN HILL, *Paignton.*

LILIUMS IN THE NORTH.

TO have a fine display of liliums a start should be made about the middle of September, with such bulbs as L. candidum, L. excelsum and L. Regale. The old Madonna lily is certainly *par excellence* as a border bulb. The chaste and wax-like flowers produced on stout stems made a charming glow of white on our herbaceous borders throughout the latter part of July and well into August. The other kinds mentioned helped to make the lily show, but candidum being more numerous and so handsome, outshone the others; the flowers, too, are powerfully fragrant. The stems stood from 3ft. to 4ft. high, and from sixty-three stems 453 flowers and flower buds were produced; really a fine display. Our method of treating the bulbs when they arrived here in September was to make ready several 10in. pots, and set four bulbs—which were fairly large—in each pot, using a soil mixture of loam, old lime and sea sand. Then we set the pots in the late peach house, and not until the bulbs started into growth did they receive very much water. L. excelsum and L. Regale were treated in the same manner, but the bulbs of these kinds being smaller, pots of a less size were used, and under this treatment the bulbs made good progress, being well rooted, and having fine fresh green leaves and strong centres at the middle of December. In the autumn, two of the herbaceous borders were trenched and the plants overhauled and re-arranged, and on these borders stations were left for the liliums. It was a day in December, when the maximum temperature registered 52°F., that we set out the liliums in the open borders. Holes were taken out at the stations and a little good soil put in the bottom of each hole, and then all around the carefully turned out ball of bulbs—which each pot had contained. It was interesting to observe at the time that the border earth was not really cold at this late period of the year. In the month of March the rosette-like leafy stems of the liliums were strong and healthy and stood boldly out on the borders. L. excelsum was in flower a little before candidum, which expanded its first bloom on July 19th, while L. Regale was a few days later. The bulbs of L. Regale were somewhat small, but we hope for better results from this fragrant lily as the years go by.—DAVID ARMSTRONG.

A GOOD SITUATION FOR SENECIO GRAYI.

CULTURE OF ÆTHIONEMA GRANDIFLORA.

MANY people whom I know find the culture of the above plant very difficult. In fact, a few months ago a very experienced alpine nurseryman remarked to me that he regarded it as one of the most difficult plants to transplant and establish. For my part, I have found it one of the easiest, providing

Digitized by Google

the conditions are right. My advice to those who wish to succeed with it is as follows: Choose the hottest and driest bank in the garden and dig a hole, part way down the slope, about 2ft. deep and 18ins. across. Fill this hole with broken bricks and mortar from some recently demolished building, to within 6ins. of the surface, and then plant the specimen in some of the lightest and poorest soil available. I have never found this treatment to fail. Only last winter I transplanted a dozen which had sent their roots down 2ft. into the brick rubble. Of these old plants, some of which were ten or twelve years old, only two died.

The plant is a native of the Levant, and apparently can only thrive in almost bone-dry material. In my garden it seeds itself quite freely, and youngsters frequently spring up near the parent plant.—G.

FRENCH METHOD OF CULTIVATING EARLY STRAWBERRIES.

AN interesting and somewhat unusual method is employed by some French gardeners for obtaining early, fine and delicious fruit in the open.

The largest obtainable barrel has holes, 2ins. in circumference and 9ins. apart, made all over its surface. One end of the barrel is knocked out, the other has a pivot placed through it. The barrel is well tarred and placed in a sunny, sheltered position in the garden. It is then filled with good loam, into which a liberal amount of well rotted manure and wood ash have been incorporated. This soil is firmly packed down, leaving a fine open tilth at the top of the barrel. A young strawberry plant is firmly planted in each hole (in the autumn, of course), and also 9ins. apart round the rim of the barrel.

Thus, in a small space quite a number of strawberry plants can be grown with very little trouble, for when once the barrel is planted, a copious daily watering, the removal of runners and turning the barrel on its pivot every day (to ensure all the plants having an equal amount of light), are all the "cares" which strawberries so grown require.

Moreover, a strawberry barrel is a beautiful sight when the green, white and red colouring of the leaves, flowers and fruit smother it. Owners of small gardens might do worse than try this attractive French method of growing strawberries. The plants and soil should be renewed every year.—VICTORIA SLADE.

SOME BERRIED SHRUBS FOR WALLS.

IT is not always advisable to plant subjects that grow close to the wall or require training to it in this manner. Of course, other cultivators may prefer such kinds of plants, and for filling in a small space they are undoubtedly the best. But if we, in imagination, look at a long wall, I think the best effect would be obtained if a few specimens of a more or less bush form were mixed with those clinging close to the surface of that wall. Furthermore, several dwarf-growing plants, such as skimmias, planted at the foot of the wall and allowed, to grow almost without restriction, would add to the general effect, certainly they would add to the interest. Before any specimens are planted the soil should be prepared; if of a poor nature, turfy loam, old and fibrous, from an upland quarter, should be added; also some half rotted leaf-soil. Where the soil is clayey and some of the sub-soil from the foundations has been mixed with the surface portion, the leaf-soil and some old lime rubble will improve the quality generally. Rotted manure should be used freely where soils are light and poor. The following are a few suitable kinds: Akebia quinata, Celastrus scandens, berberis, pernettyas in variety, pyrus, the snowberry and the wild guelder rose.—GEORGE GARNER.

THE TREATMENT OF SALAD PLANTS.

EXCESSIVE moisture, both in the soil and the atmosphere, destroys more green salad plants than frost does. We all appreciate tender salad plants throughout the year; of course, we eat more of them during the heat of the summer months, but we ought to use them in the winter, too. Young plants of the cos lettuce should be grown well in the open border till the end of November. After this date, for about six weeks, there is not much new growth made in the open air, but if the plants are carefully lifted and transplanted about 9ins. apart in a rich soil in an old house or pit, the structure kept closed for two weeks, then carefully ventilated, the plants will soon make progress. Directly they are planted, water liberally once, then keep the soil dry on the surface. Early in January a teaspoonful of nitrate of soda to three plants and water. It is not necessary to tie up such cos lettuce to cause blanching, as, being so close together, they fill the whole space and blanch nicely, being fit to use early in the new year. Cos varieties of the hardy type may be grown in raised borders outside, but the cabbage varieties are the favourites. Sow radishes very thinly in a cold frame, they will be fit to pull in six weeks time, then defer any more sowings till mid-January. Beet will be in store and celery in the ridge, both being protected from severe frosts. Mustard and cress are best grown now in rich soil in boxes in a greenhouse temperature and the winter tomatoes will require about ten degrees more heat. If onions are scarce, start a few shallots in boxes of soil.

LIFTING AND STORING OF ROOT CROPS.

IN the kitchen garden the lifting and storing of root crops ought to occupy a reasonable amount of time because the supply of vegetables later on will largely depend on how such work is performed. The most important crop is, perhaps, the potato, but this was dealt with in a note in THE GARDEN of September 5th by Mr. Garner.

Onions can be lifted and thoroughly dried, and when ready, or on a wet day, the bulbs should be tied in small bunches and suspended from the roof of a dry, airy shed. A little frost will do onions no harm, providing they are dry; if not, their keeping qualities will be impaired.

Beetroots must be lifted, and, to prevent undue bleeding, do not cut off the foliage near the roots; it is best to leave a few inches of leaf stalk.

A frost-proof shed is needed, and the roots are placed in sand or sifted ashes. Carrots, salsafy, scorzonera and turnips need similar treatment.

The tuberous variety of artichoke is lifted directly the foliage dies down, or slugs will injure the roots if they are left in the soil for any length of time.

Parsnips are best left in the ground until they are required for the kitchen, the flavour being improved by a little frost. If we experience a spell of hard weather the bed may be protected with a sprinkling of litter or fern bracken. Celery will also need protection, and, like the parsnips, this crop is lifted when needed.—T. W. B., *Chepstow.*

MIGNONETTE IN POTS FOR WINTER FLOWERING.

A FEW pots of mignonette in the greenhouse late in winter and throughout the spring will add considerably to the attractiveness of that structure at a season when flowers, other than those from bulbs, are scarce. Extra fine spikes of bloom may be grown if a little trouble be taken with the plants. I well remember three pots of mignonette being staged at a spring exhibition; one pot contained one plant with one huge central spike, another contained one plant, stopped and induced to bear three spikes of medium size; the third pot contained three plants confined to one spike each. All were well grown and very beautiful, and readers may adopt all, or one, of these three methods of culture. To succeed, the cultivator should take note of the following hints: The present is a good time to sow the seeds; if sown too early the resultant plants are liable to bloom too soon and so cause disappointment. It is not wise to transplant seedlings, so the seeds should be sown in small pots filled with good loam and a small proportion of old mortar rubble. Drain the pots adequately, cover the seeds lightly, place the pots in a cold frame, water at all times carefully, thin out the seedlings to the desired number in each pot. Stop a few seedlings at the end of October or a little later; allow others to grow unstopped to flower first. Winter on a greenhouse shelf, re-pot in January and feed the plants when the large pots are filled with roots.—G. G.

VEGETABLE AND FLOWER SHOWS

VINCENT SQUARE

THERE is nothing of the showman about the Royal Horticultural Society. On September 8th last it was supposed to be Vegetable Day at their hall at Westminster, but the regular visitor might well have been excused for imagining that the clock had stood still and it was a fortnight ago, when gladioli were the flowers of the day.

But after looking around, the vegetables were found to be there, and very good vegetables they were, even though quantity was lacking. It may be that most of the thousands of Fellows do not care to exhibit, or perhaps the rather meagre schedule did not sufficiently encourage them to enter the lists.

Next to the collections of vegetables, which were admirable, came, in order of excellence, potatoes, onions, leeks, parsnips and carrots. Peas were very good, there were only four dishes and three of these were of Mr. Gladstone—the fourth was Duke of Albany. It was rather early for celery, but Brussels sprouts were as good as one would wish at Christmas. Potatoes were beautifully clean and perfect in shape. Perhaps the outstanding varieties were King Edward, Majestic, Abundance, Dargil's Early, Witch Hill Seedling and Katie Glover, but the general quality was very high. The chief prizewinners were Mrs. Jenner, Wenvoe Castle, Cardiff; Mr. R. Chetwynd Stapylton, Great Berkhamsted; and Mr. R. H. Ling, Berkhamsted, in the collections. Mr. G. Thorn, Wellesborough, for potatoes; Viscount Hambleden for immune potatoes, onions and saladings and various single dishes of vegetables. In the last named Earl Beatty, Mrs. Thorn, Mrs. Austin, Sir Joseph Tichborne, Rev. J. Davies, Mr. G. Thorn and Mr. H. W. Henderson won various first prizes.

Gold Medal DELPHINIUMS

PLANT NOW for a good display next Summer.

We have pleasure in offering the following Delphiniums, each of which gained an Award of Merit at the R.H.S. Trials held at Wisley this Summer :—

Blue Princess, **10/6**; Mrs. Townley-Parker, **7/6**; Queen Mary, **2/6**; Constance, **21/-**; Blue Boy, **7/6**; Col. Sir W. Murray, **2/6**; Mrs. Shirley, **5/-**; Mrs. C. McIver, **5/-**; Lord Derby, **7/6**; W. T. Ware, **3/6**: Marjorie Ferguson, **10/6**; Norah Ferguson, **5/-**; E. Bromet, **21/-**; Mrs. A. J. Watson, **5/-**; Mrs. H. Kaye, **5/-**; Millicent Blackmore, **7/6**; Rev. E. Lascelles, **3/6**

One of each for **£5 10s.**

One doz., our selection, **£3**

Other choice named collections :—
15/-, 22/-, 30/-, 42/-, and **65/-** per doz.

Fruit Tree Banding

A Remedy for Caterpillars

No matter how small or large the orchard, it pays to use Stictite Tree Banding Compound, as a means of checking leaf-eating caterpillars.

Winter Moth is responsible for the bulk of the leaf-eating caterpillars. It rises from the soil early in October or late September, and the females (being wingless) at once crawl up the tree trunks in order to deposit their eggs in the branches.

By banding the trees with Stictite in the autumn, you can prevent the eggs being laid, and so avoid having to spray for the caterpillars in the spring.

1 lb. of Stictite will do 9 to 12 trees of about 8 inches diameter.

½-lb., 1/6 (postage 6d.); 1 lb., 2/9 (postage 6d.); 2 lb., 5/- (postage 9d.); 4 lb., 10/- (postage 9d.); 7 lb., 17/6 (postage 1/-).

Best quality Greaseproof Paper, 5 ins. wide :—6 yds., 2d.; 12 yds., 3d.; 25 yds., 6d.; 50 yds., 9d.; 100 yds., 1/6; 200 yds., 2/6

Write for Descriptive Folder

Stictite is sold by Nurserymen, Seedsmen, Florists, Ironmongers, Chemists, and Stores. If any difficulty, please write to Abol Limited, 9 Beltring, Paddock Wood, Kent.

Digitized by Google

A splendid collection of pot fruits was again shown by Mr. J. C. Allgrove. His peaches, nectarines, plums and apples were models of cultural skill. Messrs. T. Rivers and Sons had pot vines bearing goodly bunches of fruit, peaches, nectarines, plums and apples of enviable quality.

Chief among the flowers were dahlias, which we note elsewhere. Gladioli were again very numerous and well shown by Messrs. R. H. Bath, Limited, the Orpington Nurseries and Mr. A. Edwards, who all set up very attractive collections. The Orpington Nurseries had several good seedlings, and Messrs. Bath showed Sapho, a slaty puce coloured flower, and Romance of orange base shaded with puce. But generally the varieties were the same as a fortnight ago.

Roses were fresh and good, though perhaps a trifle small. Messrs. Chaplin Brothers, Messrs. Wheatcroft Brothers, Mr. George Lilley and the Rev. J. H. Pemberton were the exhibitors. Anne (deep pink) and Bertha Turner (of lighter colour) were good novelties, while of the older sorts Betty, Lady Inchiquin, Innocence and Mabel Morse were very charming.

Some huge spikes of Lilium tigrinum splendens grandiflora were shown by Messrs. R. Gill and Son, who said they grew it 15ft. high with thirty-eight flowers on a stem.

Among general border flowers Kniphofia Mount Etna, shown by Messrs. Isaac House and Sons, was magnificent. Messrs. B. Ladhams, Limited, had an interesting collection of hardy lobelia seedlings. Astilbe Granat, by Messrs. M. Prichard and Sons, is very decorative, and they also had the elegant Gaura Lindheimeri.

ORCHIDS.

ODONTOGLOSSUM ENCHANTRESS (Anzac × Colossus).—This very pleasing hybrid bore an arching spike of eleven large flowers of the well known amabile type, but with much broader segments than usually seen. The flowers are rose tinted, handsomely blotched with reddish purple, the labellum broadest at the apex, white, with prominent red-brown blotching on the central area, and a spiny crest of bright yellow colour. Award of merit. Shown by Mr. E. R. Ashton, Broadlands, Camden Park, Tunbridge Wells.

LÆLIO-CATTLEYA SENATOR VAR. TITANIC.—A very fine production resulting from the crossing of Lælio-Cattleya H. T. Pitt with Cattleya Tityus. The unusually large flower had the sepals and petals of rosy mauve colour, the latter effectively crisped on the apical margin, the expansive labellum, which was the chief organ of attraction, being of rich velvety crimson colour; while each of the lateral lobes bore a yellowish disc derived from Cattleya Warscewiczii, one of the parental species. Award of merit. Exhibited by Messrs. Black and Flory, Slough.

THE DAHLIA SHOW

THE National Dahlia Society is to be congratulated on the success of its Annual Show, which was held at the Royal Horticultural Hall, Westminster, on September 9th last.

The large trade collections of lovely blooms of all the different types presented a most attractive appearance and added greatly to the general effect. Some of these collections had been arranged for the previous day's meetings, but the exhibitors added some fresh blooms, while Mr. H. J. Jones, Mr. J. T. West, Mr. C. Turner, Messrs. Waterer, Sons and Crisp, Messrs. Jarman and Co., and Mr. J. W. Forsyth, brought entirely fresh blooms, greatly to the advantage of the Show. Gold medals were awarded to Mr. West and to Mr. Jones, while Messrs. J. Cheal and Sons received a large gold medal.

Although the formal show and fancy dahlias, which held the affections of our grandfathers, and some of our fathers, have long since ceased to retain their high place, the Dahlia Society rightly keeps a few classes for them, and we noted that more than a few visitors paused to admire their perfection of shape and colour value. Messrs. Wm. Treseder, Limited, seem to be the only trade growers of them and they staged twenty-four perfect blooms of W. Girdlestone, Pandora, Willie Garrett, Mrs. Chamberlain, Charleswood and other sorts. The best amateur exhibitors of these old-time dahlias were Mr. A. J. Barnes, Bedford, and Mr. H. Lagden, Shenfield, whose blooms, though a trifle smaller than Messrs. Treseders, were perfect in form and colouring.

It was interesting to note quite a revival in the dainty little pompon dahlias, which are really the show and fancy type in miniature. The season has been far from ideal for the production of perfect examples of these fascinating little flowers, but Mr. A. J. Barnes, Bedford; Mrs. Courage, Crawley; and Mr. A. E. Poore, in the various sections, had the best collections we have seen for a long time. Their varieties included Nerissa, Bacchus, Regulus, Darkest of All, Glow and Sunset.

For real value, both in the garden and as cut flowers, the miniature peony-flowered has nearly everything in its favour and we confidently anticipate that this is *the* dahlia of the future. The best varieties make compact plants of medium height that bear plenty of flowers of delightful colours over a long period. At the Show there was an almost bewildering variety for anyone to choose from. In the open classes Mr. A. J. Cobb showed St. Andrews, Mrs. W. Childs and Sweet, while in the amateurs' classes a first prize was won by Mr. M. Howard of Chesham, with six vivid blooms of Fuzee. We also noted, of this type, Hilda D. Wheeler, Sparklet, Helen, Sunset, Kenneth, Crimson Glow, Sunbird and Picture, while the miniature peony-flowered type was used in all the most pleasing decorative exhibits.

The newer cactus dahlias have been immensely improved in habit and now there are plenty to be had with stalks so long and stout that the blooms are carried well above the foliage, so that in addition to their charms as show flowers, they have a distinct garden value. Usually it is the varieties which have flowers made up of rolled and curled florets that find most favour with exhibitors and in addition to this charm of uncommon form they possess practically every desirable shade or combination of colouring.

In the competitive classes, most of the blooms were of varieties of the type above mentioned. In the open division Mr. H. Woolman won the first prize for six blooms each of twelve varieties, with a magnificent exhibit. His best sorts were Gloriosa, Alabaster, Sidney Jones, Ballet Girl and A. E. Amos. Mr. J. Stredwick and Son were second, but in the class for twenty-four blooms shown on boards the positions were reversed, and Messrs. Stredwick were first. They included Ruddy Glow, F. W. Fellowes, Southern Maid, Erica and Supreme.

Mr. W. J. Cramp, an amateur from Streatham, was first with twelve varieties and his excellent collection included Meridian, Virginia and Mammoth. He was also the champion exhibitor of cactus varieties in the amateurs' section, while Mr. A. Brown, Seagrave, had the best six varieties. In the class for twelve blooms in four varieties, shown on boards, Mr. A. F. Tofield of Southampton, had a beautiful collection. Mr. A. Brown was very successful in the classes for amateurs who do not employ any paid assistance.

Next in garden value to the miniature peony dahlias we should place the small decorative type, which should please those who like a touch of formality in their flowers, and these, also, were freely shown and of considerable beauty. Earl Beatty, Reigate Priory, won the first prize with very attractive blooms of Raider, Tipsy and Marriena in the open class, while Mr. M. Howard had the best in the amateurs' section.

The collarette dahlias found favour with a considerable number of the visitors, who were charmed with the quaint frills, often of a distinct colour, on the blooms. There seems a slight tendency to show varieties with these quills nearly as long as the ray florets, but the most attractive sorts were those in which the quills were not much more than half way across the florets. Messrs. Wm. Treseder, Limited, were awarded the first prizes in the open classes, but their varieties were unnamed and so the exhibits lost a deal of their value.

In the amateurs' section Mr. F. Gregory, Luton, won both first prizes with excellent collections of Eden, Admirable, Bonfire, Regularity and other good sorts.

The decorative classes were very popular and many quite artistic arrangements were seen, both in the dinner tables and the vases and bowls. Mrs. Courtney Page, Enfield, and Mrs. W. Yandell, Maidenhead, were the most successful lady exhibitors.

The new class, in which the Monro Challenge Cup was offered for the best floral designs to illustrate the decorative capabilities of the dahlia, brought only Messrs. Wm. Treseder, who were awarded the cup. They had a number of conventional arrangements, suitable for all occasions, from the cradle to the grave, which were well executed.

A large number of seedling dahlias were selected for trial at Wisley, but as these are purely provisional awards, we feel that no useful purpose would be served by recording them, especially as some of the names have been previously used and must be changed.

EDINBURGH SHOW

THE splendid display staged at Edinburgh on September 9th, 10th and 11th last, under the auspices of the Royal Caledonian Horticultural Society, was probably the largest and finest horticultural exhibition ever held in Edinburgh. Since the occasion of the last International Show marked progress has been made in all branches of horticulture, and the developments and the results of the last twenty years were clearly evident from the numerous exhibits put up at the Industrial Hall. It is a matter of difficulty and often of anxiety to find material to stage at an autumnal show, but in this, Scotland excels. The weather conditions of the few days previous to the Show were against the production of fine blooms, but the majority of the exhibitors are to be congratulated on their displays. Dahlias and gladioli took pride of place on the majority of stands where hardy herbaceous flowers were shown. The former were especially good, and with their variety of colour, size and form largely contributed to the excellent decorative effects of the tables. In the floricultural world, Scotland, to judge from the high standard reached by all exhibitors at the Show, retains her position, of which she may well be proud, and, although limited to a certain extent by climatic conditions, is still capable of producing flowers, vegetables and fruits which rank as some of the finest in the world.

Probably the most outstanding exhibit in the Show was that staged by the Parks Department of the Edinburgh Corporation, under the able charge of Mr. J. T. Jeffrey. Full use was made of the space at their disposal, and a novel bedding-out scheme—in which asters,

Digitized by Google

celosias and begonias were the chief objects—was admirably carried out. In the centre of the beds two paved paths led up to a small pool and fountain. Tortuous paths ran down each side and, while, no doubt, enhancing the general appearance of the exhibit, seemed a trifle out of place if one has regard to the attention which must be given to such an arrangement in practice.

There were a few rock gardens also laid out in various corners of the hall. One of the most effective was that designed and carried out by Mr. Maxwell Hart of Glasgow. The central theme was a trickling stream ending in a small pool. The setting was a simple and a natural one, while the general design left nothing to be desired. Heaths and ferns, notably scolopendriums, predominated. The exhibit was undoubtedly a a lesson to the amateur as to what could be undertaken in a small space and also at little cost. Messrs. Laird and Dickson of Edinburgh employed many varieties of heaths in their rock garden, where a stream was again the principal feature. In addition to the garden, a well arranged and constructed rock bank was made, and contained many of the choice alpines, notably gentians. In Mr. David King's scheme shrubs predominated, and altogether the effect was a pleasing and attractive one. The small semi-formal water garden laid out by Messrs. Backhouse of York attracted considerable attention. Ornamental foliage shrubs were employed as a background to the more choice dwarf subjects planted on a walled bank.

In the general exhibits that of Messrs. Dobbie and Co., Edinburgh, probably attracted more attention than any other, and it fully deserved the large gold medal which was awarded to it. The general effect was excellent. The roses were all in fine condition, and all the leading varieties were included on the stand. Messrs. McGredy of Portadown again excelled with their collection of roses. All the varieties were in fine condition, and several novelties, such as Gwyneth Jones, were represented. Many firms took full opportunity of the space at their disposal and had a tasteful display of both flowers and vegetables. Messrs. Austin and McAslan of Glasgow staged a fine collection of vegetables, the appearance of which was considerably enhanced by the background of large-flowered gladioli, which were displayed in spray vases. In addition to this stand a fine collection of potatoes was also staged, together with a collection of alpines and rock garden subjects. Messrs. Daniels of Norwich followed much the same style of exhibit. A representative collection of vegetables was shown, also many of the leading varieties of apples and their new September Black Currant.

The few exhibits of vegetables were staged by Messrs. Sutton and Sons, Carter and Co., and Tillie White and Co. of Edinburgh. On Messrs. Sutton's stand tomatoes (red and yellow) predominated. All the vegetables were in good condition, and the method of arrangement left nothing to be desired.

The only exhibit of clematis was that arranged by Messrs. L. R. Russell, who staged a fine collection of plants in pots. The notable variety Crimson King was again in the forefront of the exhibit. There were numerous exhibits of herbaceous flowers, and the majority of these showed a wonderful selection in hardy border flowers, considering the late season. Messrs. Forbes of Hawick included some of their fine pentstemons on their stand. Arranged in the mass they looked exceedingly well. Mr. W. Wells, Messrs. Stuart and Pearson and Messrs. Baker's exhibits were of a general nature, as was that of Mr. John Downie of Edinburgh. Messrs. Rich and Co. showed phloxes, displayed, perhaps, not to the best advantage, in spray vases. Mr. T. Smith of Newry staged a fine exhibit of shrubs, including heaths and other hardy representatives of the border.

Mr. James Vert was again to the fore with a fine collection of hollyhocks; while Messrs. Blackmore and Langdon staged a fine array of double begonias which attracted considerable attention. Roses in spray vases were shown by Mr. Thomas Robinson of Nottingham, including all the better known sorts; while Delphinium Pedigree Seedling and large-flowered gladioli formed the exhibit of Messrs. Hewitts of Birmingham. A novel exhibit of miniature gardens in kerbs was arranged by Messrs. Thomas Milhorn and Sons, Edinburgh. There were many novel and extremely artistic designs suitably displayed in all sizes and shapes of bowls. Perennial scabious were in the capable hands of Messrs. Isaac House, who were also showing a brilliantly fiery coloured new tritoma named Mallenders Mount Etna, which appeared to be a valuable addition to the existing number. An exceedingly fine exhibit of chrysanthemums was staged by Messrs. Keith Luxford; all the flowers were of good size and form and were admirably displayed. Notable varieties were Elsenham White, Early Buttercup (yellow) and Red Almirante. Messrs. E. F. Fairbairn of Carlisle showed a collection of phloxes and also some excellent dahlias, the blooms of which were almost perfect in colour and size. A brilliant array of colour and bloom was produced by the stand so well arranged by Messrs. Thyne and Son of Dundee. Dahlias were prominent, and their new dwarf variety, Paisley Gem, of a pleasant shade of orange, was notable. This variety should prove a valuable adjunct in all bedding-out schemes. Messrs. Lowe and Gibson staged their excellent primulinus gladioli, the flowers of which were in excellent condition. Carnations were in the capable hands of Messrs. Allwoods and Messrs. C. Engelmann. The former made a special feature of their new Allwoodii in ample beds, while their stand was reserved for the perpetual flowering varieties. Messrs. C. Engelmann had a collection of perpetual carnations which gained the first prize in its class.

The exhibits of fruit reached a high standard of excellence, which was remarked upon on all sides. Mr. R. C. Notcutt of Woodbridge had a fine collection of apples, all the leading varieties being represented. Fruiting sprays of cotoneasters, berberis, pyrus and euonymus greatly enhanced the appearance and setting of the baskets of fruit. Messrs. Bunyard also staged some excellent apples in baskets. An interesting collection of grapes, grown in a greenhouse without heat, was also shown by this firm. Another well arranged exhibit was that of Messrs. Storrie and Storrie, Glencarse, consisting of fruit trees in pots and also baskets of apples, pears and plums. An interesting collection of old Scottish pears was shown by the Carse of Gowrie Nursery Company, in addition to an extensive display of apples, pears, plums and currants. These two latter exhibits served to show the high standard of quality and excellence which can be attained in fruit cultivation in Scotland.

In the amateurs' classes the entries were numerous—somewhere in the neighbourhood of 2,000—and the competition exceedingly keen, especially in the classes for grapes, where there were some exceptionally fine bunches shown. Mr. Don McKinnes, gardener to the Earl of Strathmore, was a successful competitor in these classes. In the vegetable classes the standard reached was very high and the judges were set no easy task. The classes for decorative effect were well patronised and produced some striking displays, while the floral classes attained a very high level of excellence.

LIST OF AWARDS.

Large Gold Medals: Messrs. Dobbie and Co., Edinburgh, roses, dahlias and sweet peas; Messrs. Sutton and Sons, vegetables; Edinburgh Corporation Parks Department.

Gold Medals: Messrs. Allwoods, carnations; Messrs. Austin and McAslan, gladioli and vegetables; Backhouse Nurseries, Limited, rock and formal garden; Messrs. Bunyard, hardy fruit; Messrs. Carter and Co., vegetables; Messrs. Dickson and Co., roses; Mr. Maxwell Hart, rock garden; Messrs. Isaac House, new perennial scabious; Messrs. Laird and Dickson, rockwork; Messrs. S. McGredy, roses; Mr. R. C. Notcutt, hardy fruit and berried shrubs; Messrs. Storrie and Storrie, pot fruit trees.

INTERESTING ANSWERS

I have been bothered with my asters going off after being planted out in beds and borders, so am sending you some for inspection. I wondered if it was due to a fungus disease or a deficiency of humus in the soil. I found a small transparent maggot just over an inch long at the root of one I inspected the other day, but that seems to lead me no nearer a solution of the difficulty. Most gardeners term it shanking, and bother no more about it, but I feel there must be a remedy and would feel grateful for advice. I may say they were grown in cold frames.—E. EKINS, *Bedford.*

Asters and several other kinds of plants, suddenly die, usually when they approach the flowering stage. The cause of death is a fungus, which reaches full power to destroy about the flowering time of the plants. Grubs generally come where there is decay. Dig the soil deeply this autumn, and scatter on its surface, afterwards, three pecks of lime per square rod. Leave it so throughout the winter, and next spring sterilise the soil with a formalin solution, one pound to twelve gallons of water. To the compost used for raising the seeds, add some old lime rubble.

A reader in Donegal asks why Sparaxis pulcherrima and Alstrœmeria aurantiaca fail in a well drained border, with limy soil, facing south.

The sparaxis should have some rough peat added to the general soil in which the plants are to be grown. Good loam and leaf soil should form the bulk of the compost. A warm, sheltered border is the best position, and not any, or very little, lime in it. It is well to raise the border, to plant about 4ins. deep at the end of September, and to protect from frost with dry litter. The alstrœmeria requires a well drained soil, quite 2ft. deep and a warm position. Plant 9ins. deep and 12ins. apart; mix half soil with that used for covering. Some old mortar rubble, mixed with the soil immediately over the drainage portion, will be beneficial in this case. Where heavy soils obtain, raise the border 9ins. or so.

I shall be greatly obliged if you will kindly give me a little advice on green manuring, also the most economical varieties of seeds to use.—V.

White mustard and vetches are the crops most generally raised at this season for digging or ploughing in while in full growth. The plants derive their chief constituent—carbon—from the air; they are shallow rooting and, furthermore, possess very small roots, so they do not exhaust the soil, but greatly enrich it when buried beneath the surface to decay. Seaweed, too, is a valuable manure of this character, where it can be obtained.

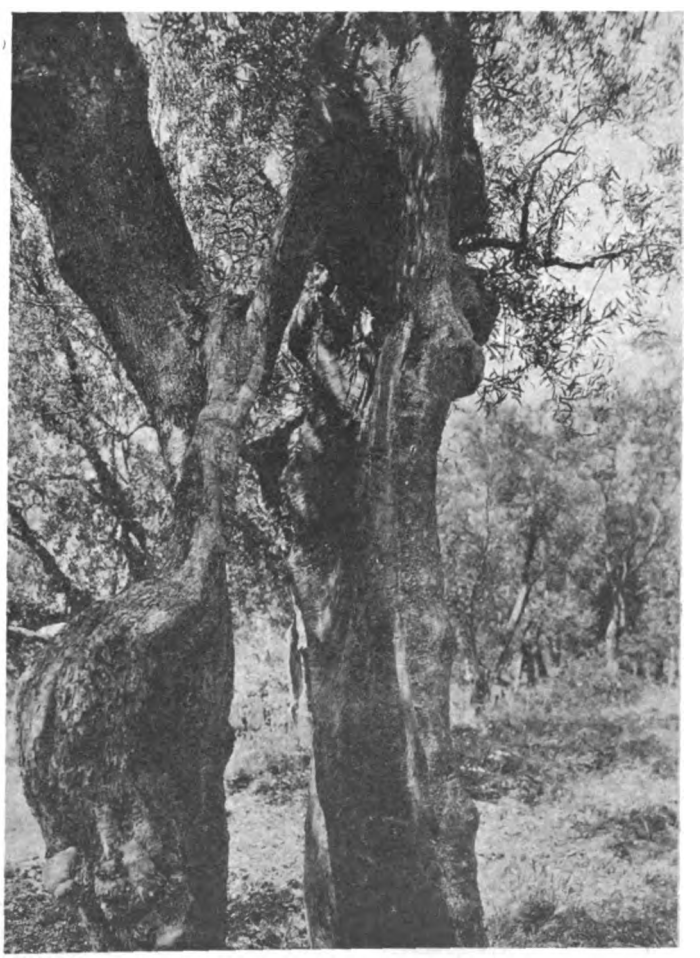
TREE SURGERY

TREES, as well as humans, are susceptible to physical injuries. Whereas, among men, the repair of the body by surgery has become a fine art, tree surgery, in this country at any rate, is in the same state as was human surgery in the dark ages, when limbs were lopped off and the stump seared by fire or covered with a coating of pitch.

In one or two countries tree surgery is practised. There is a firm in the United States which specialise in the healing of trees and who advertise that last year they did $1,500,000 worth of business. This may sound enormous to us, whose knowledge of this art, for it is an art, is rudimentary, but it must be remembered that the United States is a large country and that in many states fine timber is rare and so is jealously guarded and tenderly cared for. America, however, is not the only place where tree surgery is practised, for in Italy blains and boils in certain trees have been operated on for centuries. Those who have walked through groves of olives or have taken note of mulberries in the fields, will have seen the weird and picturesque contortions which surgery has given to many of the older trees. This is particularly the case in olives, which are often so cut away that it is a marvel how the narrow lath of wood remaining can bear such a noble crown. Trees are often seen completely cut down the middle, and yet year by year they bear a heavy crop. In the mulberry the knife is less often used, which is no doubt partly caused by the fact that mulberries are rarely allowed to exist for many years. There is a vital difference between tree surgery in the United States and in Italy. In the former it is used to preserve a beautiful object and so the surgery is as inconspicuous as possible, in the latter the preservation is entirely on economic and not on æsthetic principles.

In the British Isles we have so much fine timber that in the past there has been little necessity for the evolution of this branch of forestry. If a fine old tree is damaged and has to be removed, there is usually another close at hand to which we can transfer our affections. Our repair of damage is either non-existent or crude in the extreme. How often do we see the jagged remains of a branch which may have been broken by a gale years before with no attempt at arresting rot and decay? If anything has been done at all, it is only the sawing off of the jagged ends and an unsightly lick of tar on the open surface or an even more unsightly iron plate. Occasionally cement is used to fill up an ugly gap or hollow, but nothing is done to blind the cement. If a branch is dangerous, there are three remedies in this country: its amputation, with never a thought about the appearance of the tree, an ungainly prop underneath in the case of a lower branch, or a rusty iron chain to moor it to the upper structure of the tree. It is, perhaps, unnecessary here to go to such lengths as they do in America, but many a fine specimen could be saved if the trouble was checked in time. There is hardly a garden or a park which has not one tree which lords it over its neighbours and which



A TYPICAL OLIVE IN NORTH ITALY, WHICH HAS BEEN SURGICALLY TREATED SOLELY FOR ECONOMIC REASONS.

Digitized by Google

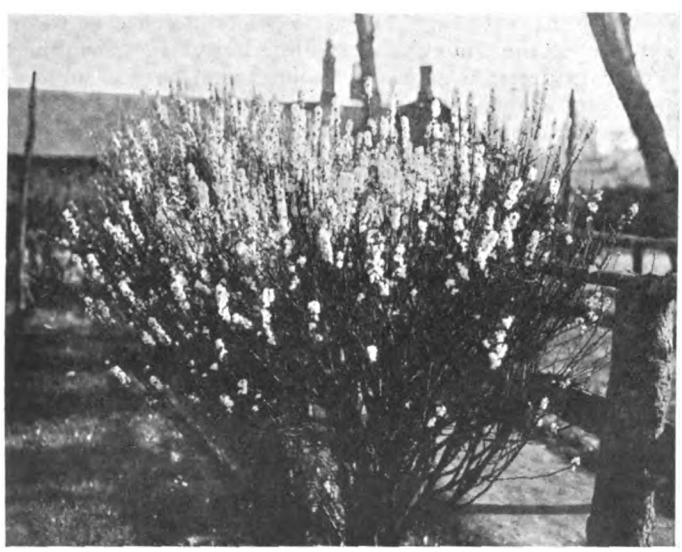
is pointed out with pride by its owner. It takes longer to grow a new lord than to destroy an old one, and in order to save these from the frailties of old age for as long as possible, we might well take a leaf from the book of the United States' tree surgeons and learn a little of what they have to teach us.

I believe I am right in stating that there is no one who practises tree surgery in this country. This is an art which is not so easy as might appear on the surface. It does not consist solely of covering up damage caused by snow or wind or in lopping off dangerous branches and covering the gash in as inconspicuous a manner as possible. There is much decay that takes place in an old tree that is never seen on the surface. This can be checked if taken in hand before it has gone too far. In many cases a diagnosis can be given and sometimes the cause removed. It must be remembered that few trees die of old age, and that disease will attack a tree as it will a human being.

The British Isles has been noted for its noble trees for so long that it is surely our duty to take every care of them. No place is so prolific in specimen trees that even a small percentage can be spared. From the letters which are received by *The Garden* and *Country Life* from time to time it would surely pay some firm to practice the valuable profession of tree surgery. E. H. M. C.

A WINTER GARDEN

THE title that heads this article does not indicate, as might be imagined, a miniature Crystal Palace housing a few palms and a band, but a special bit of ground devoted entirely or almost entirely to shrubs, plants and bulbs of which the flowering season extends from the end of November, when the last of the chrysanthemums is over, to the beginning of March, when the first daffodils open.



DAPHNE MEZEREUM IN A COTTAGE GARDEN.

HELLEBORUS NIGER IN THE WINTER GARDEN.

The exact way in which such a garden is laid out is a matter to be governed by the space available, the general contour of the ground and other considerations, which will, naturally, vary in each individual case; but it is imperative that it should be sheltered from cold winds and be open to the sun. If it slopes gently to the south or south-west so much the better, and if it is not entirely enclosed by walls there should be, if at all possible, one facing the sunniest quarter with a broad border in front of it. Backed by such a warm wall, Chimonanthus fragrans, the winter-flowering honeysuckles, Lonicera Standishii and L. fragrantissima (the latter, unfortunately, is a shy bloomer in some gardens); Cydonia japonica and its varieties; Hamamelis arborea, H. mollis and H. virginica; and Berberis stenophylla will all thrive well and bloom early, as will Garrya elliptica, the pretty pale green tassels of which are apt to get badly nipped by frost in an exposed situation. Garrya is, however, rather too strong a grower if space is limited, and the same objection applies in some measure to the forsythias and to Jasminum nudiflorum, although the long gold-starred shoots of the latter are certainly seen at their best against a sunny wall. But it is nearly as effective and takes up less room if grown on a pole or stout stakes. Azara microphylla is another shrub desirable in a winter garden for the sake of its pretty foliage, which is evergreen and weatherproof except in very cold localities.

In the border in front of the south wall may be planted Daphne Mezereum, white and red; Prunus nana, the dwarf almond, double and single; Erica carnea, E. darleyensis, E. mediterranea and E. m. hybrida, all of which will grow in ordinary loam and are less averse to lime than other members of the heath family, although they prefer a peaty soil. Between and slightly in front of these shrubby plants, some of the hellebores, H. fœtidus (valuable by reason of its handsome evergreen leaves), H. colchicum and its hybrids, and H. orientalis may find a place, together with clumps of Iris stylosa (unguicularis). This lovely winter-flowering iris is not always easy to establish and has a rather tiresome habit of flowering profusely one year and not at all the next. A warm, well drained border or bed of rather poor soil suits it best, but it is necessary to keep it well dressed with a mixture of coal ashes and soot or Sanitas powder from the time the flower-buds begin to form, as slugs are particularly partial to the flowers at all stages. In front of Iris stylosa, snowdrops and winter aconites should be thickly planted, and the border may be edged with one of the mossy saxifrages or a low-growing campanula such as C. cæspitosa or C. pusilla, the leaves of which make a neat green mass.

It is less easy to deal with the comparatively sunless parts of the garden—and however favourable its situation it is unlikely to be quite without them—but Helleborus niger, the popular Christmas rose, does not object to a certain amount of shade: indeed, it dislikes the morning sun, and as it must be protected by more or less unsightly hand-lights, it is as well not to give it too prominent a position. Sun is not absolutely essential to Petasites fragrans, if it is desired to grow this ugly thing for the sake of its early and very sweet-scented flowers, but wherever it is placed it should be planted in a large pot sunk so that the rim is just above the ground, as, unless this precaution is taken, this rampant coltsfoot will choke everything else within a radius of many yards. Omphalodes verna will produce a few of its brilliant blue blossoms in February,

Digitized by Google

JASMINIUM NUDIFLORUM IN MID-WINTER.

even out of the full sun; and the glossy green leaves of the Vincas—blue, white, single and double—are pleasant to look upon even when without a flower—a rare event.

If the garden is very small it is wisest to avoid turf altogether, otherwise a charming effect can be achieved by laying down a lawn in the centre and planting in it good specimen trees of Prunus Pissardii, P. Miqueliana, P. cerasifera (the myrobalan plum), P. Amygdalus (the common almond), Cornus Mas (the cornelian cherry), whose pale yellow blossoms, individually insignificant, look beautiful seen against a blue sky; and, possibly, Jasminum nudiflorum, grown on poles as previously suggested. In the grass should be naturalised early-flowering crocuses such as C. lævigatus, C. vitellinus, C. Susianus, C. Imperati, C. Sieberi and C. chrysanthus, as well as the ordinary Dutch crocus. A lawn in a winter garden calls for particular care in draining, and if the soil is wet and heavy it is better to dispense with one altogether and to fill the space with slightly raised beds divided by brick or stone-paved paths. One of the flowering trees may be placed in the centre of each of the beds, and the latter can be filled with bulbs and carpeted with arabis (the single variety flowers earlier than the double), polyanthus or coloured primroses. The latter will often begin to flower late in January unless the weather is exceptionally severe, and both double and single should be grown in as many colours as possible. They will seed themselves freely, but care must be taken to root out promptly any seedling which shows any tendency to revert to the wild type or is muddy in colour. The beds may be edged with tiles or stones, or with clipped box or euonymus. The gold and silver varieties of the latter make a pretty bordering, but a sharp frost is apt to catch the tips of their leaves badly.

It will add to the amenities of the garden if some kind of a shelter, even if only a wooden seat—a teak one is best—with a lean-to or pent-house roof of reed thatch, can be placed at the best point for getting a comprehensive view of the plot. If it can be managed, the shelter should stand on a platform of bricks or paving-stones raised by a couple of shallow steps from the ground level. Against this platform may be built up a rock-bed with pockets in which should be planted Iris reticulata, I. Histrio, Narcissus minimus, N. minor and N. nana (the last two are rather expensive, unfortunately); early crocuses, chionodoxas, Anemone appenina and A. blanda. These two beautiful anemones, indeed, cannot be too freely used in a winter garden. They may be planted in masses in beds or borders and will increase rapidly in a fairly warm soil, especially if in a moderately sunny situation and given a yearly dressing of leaf-mould. Both anemones may be also naturalised in grass, but A. appenina is, perhaps, best suited for the purpose.

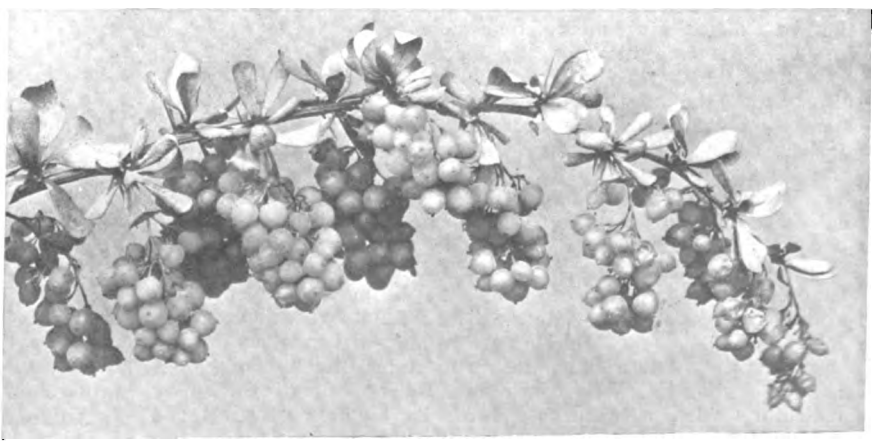
R. E. HEAD.

SOME CHINESE SHRUBS & TREES of our GARDENS

THE reason for the scarcity of many fine Chinese introductions is not only that they are not sufficiently known, but also the difficulties encountered in their propagation. Such plants as Acer griseum, Davidia involucrata, the newer Chinese magnolias and coniferæ, and a host of others, of which, comparatively speaking, there are but a limited number of plants in this country, few of which have yet set fertile seed and some possibly never will, at least in anything like commercial quantity, and which are of very difficult propagation by cuttings. It would, therefore, appear that until further seed is forthcoming from China, or existing specimens in this country set fertile seed, these plants will remain scarce, and almost unprocurable. It must, however, be remembered that while this is true of a certain class of plants, there is a far greater number of these Chinese species which are producing fertile seed and which are of easy or possible propagation from cuttings, layers, etc. The practice of grafting, as all know, should be avoided as far as possible.

Acer griseum and A. nikoense of the trifoliate class are, perhaps, two of the finest of this section, especially on account of the fine red and orange autumnal colourings of their leaves. Unfortunately, it is doubtful whether there is at present any source from which the former may be obtained, and the latter is only held in limited quantities by a few nurserymen. Seed obtained from Japan is frequently untrue to name and often of bad germinating quality. The typical form of A. nikoense has been found only in Japan; it is smaller and less pubescent than the variety from central China.

Of those with entire simple leaves A. Davidii stands first, with its distinct white striated bark. Of equally rare character is A. lævigatum, which is one of the most distinct of Wilson's acers, belonging to the section integrifolia. It is closely related to A. Fargesii, which differs by the smaller not reticulated leaves and also by the red colour of the inflorescence and young foliage. A. lævigatum has, with but little damage, passed several winters outside here at Winchester. It is one of the last species to lose its leaves at the fall of the



A WELL FRUITED BRANCH OF BERBERIS WILSONÆ.

Digitized by Google

year; right up to that time they remain a bright green colour. When grown under glass it remains evergreen throughout the year. In foliage it differs from almost any other species, the leaves being simple, oblong or lanceolate, acuminate; the margins vary from being almost entire to finely serrated or crenulate and irregularly notched. The average length of leaf is about 4½ins. to 5ins., but here they have been measured up to 7ins. long by 2ins. wide. The young shoots are of a bright shiny green.

Many species of the genus betula of Chinese origin are now to be seen growing in some of the leading gardens of this country. In order that they may be considered of horticultural value they have first to displace our native Betula alba (the common silver birch), which is a most beautiful tree. There are several Chinese species which supersede the indigenous birch of this country in the beautiful silver and

CLEMATIS MONTANA RUBENS ON AN OLD STUMP

orange colouring of their bark. Such subjects as Betula Ermanni and B. albo-sinensis and their varieties are probably the finest of the silver-stemmed species.

There is a section of the birch family which may be termed the red-barked birches. These, as the name indicates, differ from the silver-barked species in the colour of their stems and branches being brownish red and sometimes even darker. Two of the best of this class are Betula Delavayi and its variety Forrestii.

Berberis and cotoneaster are two of the most richly enhanced of shrubs through Chinese introductions, and certainly two of the most easily grown. The variations in the habit of growth of the species of berberis are great. B. candidula (hypoleuca), B. verruculosa and B. Wilsonæ make splendid additions to our rock gardens. The first two bear evergreen foliage of the darkest glossy green hue with yellow flowers in the spring, followed in the autumn by bluish black, egg-shaped fruits. B. Wilsonæ, named in honour of the great collector's wife, is unsurpassed for its clusters of coral red fruits and fine autumn colourings assumed by its foliage. Of the large-leaved evergreen section the following are well worthy of being in every collection.

B. Sargentiana, a strong, bold grower with large leathery leaves bearing a prominent venation, and with conspicuous stiff ivory white spines. Differing from and yet somewhat similar to this species is B. atrocarpa. The habit of branching is more intertwined and the leaves are smaller and smooth on the underside.

B. Soulieana is of a stiff, rigid habit and differs from the previously mentioned species in its fruits being more round than egg-shaped, and its leaves narrower and more lance-like.

Of the deciduous species, B. dictyophylla is distinct, with its white branches and large solitary red fruits; while B. aggregata Pratti, when covered with its paniculate clusters of coral red fruits, which remain on until Christmas-time, is a charming shrub easily to be possessed by every gardener.

B. yunnanensis is of erect growth and has large, prominent spines. It may be seen at its best when at the fall of the year its foliage is brilliantly tinted in red and yellow shades.

B. polyantha is a tall grower, attaining 8ft. in height. The drooping inflorescences are about 3ins. to 4ins. long, carrying up to over fifty yellow blossoms, followed by drooping clusters of small red, egg-shaped fruits, hanging in a manner similar to that of a bunch of grapes.

The berberises, like the cotoneasters, are very suitable for mass planting in poor soils under trees where few subjects will grow and nothing else give such transforming effects.

The large mauve-flowered section of buddleias is the most handsome, the most easily propagated, and thus the most frequently seen. The type of this group usually known in gardens as B. variabilis is now correctly called B. Davidii. The best varieties are magnifica, Veitchiana and superba, and of the newer varieties the most noteworthy is nanhoensis. The species are less known in our gardens, and the large woolly-leaved section is of more difficult propagation. Of such are B. Farreri and B. nivea, both of which are clothed with a dense white tomentum. B. yunnanensis and B. Forresti are also worthy of a place in our gardens on account of the silvery hue of their foliage. Unfortunately, all these species fall short of the flowering qualities and hardiness of the old B. variabilis and its varieties, and there is no member of the family known to cultivation in which may be found combined the large silvery leaves of B. nivea with the large panicles of mauve flowers of B. Davidii.

One of the finest of the Chinese shrubs is Buddleia alternifolia, differing from other members of the genus in its small alternate leaves. During June it is a charming object with its long, slender, arching branches, wreathed from end to end with an unbroken band of lilac-coloured flowers. As the flowers are borne on the previous year's wood it is important that, if any pruning be necessary, it should be done immediately after flowering.

A beautiful species, at present but little known, is Buddleia Fallowiana, flowering at the same time as the Buddleia variabilis varieties, against which its long narrow panicles of pure white flowers form a pleasing contrast. The charm of B. Fallowiana is enriched by the fragrance of its flowers, which are closely packed into the form of a cylindrical spike, each individual flower bearing at the centre of its delicate white corolla a mark of orange yellow. The silvery white foliage, most apparent in the young growth, adds to the attractiveness of this new species.

Ceratostigma Willmottianum, a member of the Order Plumbaginaceæ, may best be described as a shrubby plumbago. This is a great acquisition to the autumn-flowering shrubs. When in full flower, the season of which is long, it well holds its own in the most glorified herbaceous border, and a truer blue it would be difficult to attain in any other plant. It is a shrub of very fair hardiness for the southern counties, revelling in the full sunshine and never attaining a height of more than about 4ft.

I have chosen three species of clematis. There are many others and probably of more recent introduction, but many of the latter have not yet proved their horticultural merit.

The value of the well known Clematis montana cannot be over-estimated, being not particular as to soil, of free, vigorous growth and very free in flowering. The variety rubens with its rose-coloured flowers is a particularly fine form and should be more frequently planted.

C. montana Wilsoni differs from the type in the flowers being strongly scented and later in opening, and is, on this

Digitized by Google

account well worth growing. C. Armandii was introduced by Wilson in 1900. Its flowers are creamy white or white, rather smaller in size than those of C. montana. The outstanding feature and value of this plant is that it is another addition to our comparatively small number of evergreen climbers, possessing large trifoliate leaves of a dark glossy green colour.

The finest yellow-flowered clematis in cultivation is C. tangutica and its variety obtusiuscula. The flowers before they are fully expanded are like yellow lanterns scattered over the entire plant. A large specimen seen when in flower is a sight not easily to be forgotten. Individual flowers have been measured up to 4ins. across.

Shrubs flowering during July and August are valuable assets to our comparatively limited number of late summer flowering species.

Clethra Delavayi, flowering at this period of the year, may be considered one of the most magnificent of Chinese introductions, forming a shapely deciduous shrub of rather erect growth and producing creamy white, lily of the valley-like flowers in great profusion on long slender spikes.

Corylopsis is a generic representative of the same Order as the better known hamamelis or witch hazel. All the species are natives of north-eastern Asia and bear a common resemblance one to another. Corylopsis Willmottiæ is a deciduous shrub with hazel-like leaves and bearing drooping racemes of yellow flowers before the leaves appear in the spring. It ultimately attains a height of about 10ft., and will thrive quite well on chalk provided that it is given a fair depth of soil and placed in not too shady a position.

H. G. HILLIER.

(*To be continued.*)

TROPÆOLUMS AND BRODIÆAS

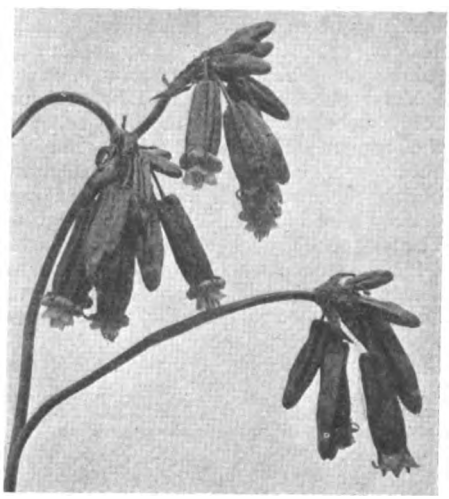
THERE is a saying that what a man does not know, he does not wish for, and certainly this saying has an element of truth when applied to many out of the way bulbs.

Let me select Tropæolum speciosum, the flame nasturtium as an example. This species is fairly well known, but how many gardeners have grown its relative, Tropæolum tricolorum? A short description may assist in giving some idea of the plant. If this subject is included in this year's bulb order, in due course you will receive one or more—depending on the confidence the writer may inspire—round or oblong brownish tubers. From one of the ends two or three thin thread-like green shoots may have sprung, which should be handled with all care, as if these are broken there will probably be no visible part of the plant outside the ground, although the tuber under the ground will remain intact.

These tubers should be potted up at once, three in an 8in. pot. They should be laid flat on the soil and covered to a depth of 1½ins. If the young shoots have developed, however, it is advisable to keep them on the soil level. A suitable compost is one consisting of equal parts of sand and leaf-mould, with an addition of loam.

The plants are best grown in a temperature not falling below 40° F. in winter, either in frames or in a cold house. The pots must be watered carefully, giving more water when the young shoots appear and are in an active state of growth, which is mostly in the course of a few weeks after the potting up. Three or four sticks 2ft. long inserted at equal distances round the rim of the pot and united at the ends with one or two cross-bands will give the stems ample support. In March or April all will be covered with small greenish five or six-partite leaves and soon after the flowers will appear on long pedicels. These are most attractive, scarlet in colour, tipped with black, and for several weeks the plants will be in full beauty. At the end of April or the beginning of May the plants show signs of withering, and water should be withheld gradually, allowing the tubers to dry off entirely. The whole pot with tubers and soil may be stored away in a warm, dry place,

VARIOUS SPECIES OF BRODIÆAS.



THE CALIFORNIAN FIRE CRACKER.

and in July or August the tubers may be re-potted. T. tricolorum is a native of Chili, from where it was introduced in 1828. Propagation is carried out by seeds, which will produce flowering plants in two or three years.

Another good plant, even less known, is T. brachyceras. This forms somewhat more robust plants, and is therefore very useful as a decorative subject for covering the stiles of a greenhouse in winter and spring. The flowers are golden yellow and do not possess such long spurs as those of the preceding species. Treatment is the same for both.

T. pentaphyllum flowers later (May–July) and may be grown in the open during the summer months. It bears a good many flowers. The outside may be a bright scarlet when fully exposed to the sun's rays, or a duller red when grown in a greenhouse. The interior is pale green with small purplish spots. A good plan is to pot it up early in the year and bring it to its summer position after hardening off.

T. tuberosum is not so satisfactory, as its blooms generally appear late in the autumn and are often destroyed by early frosts. A warm, sunny spot

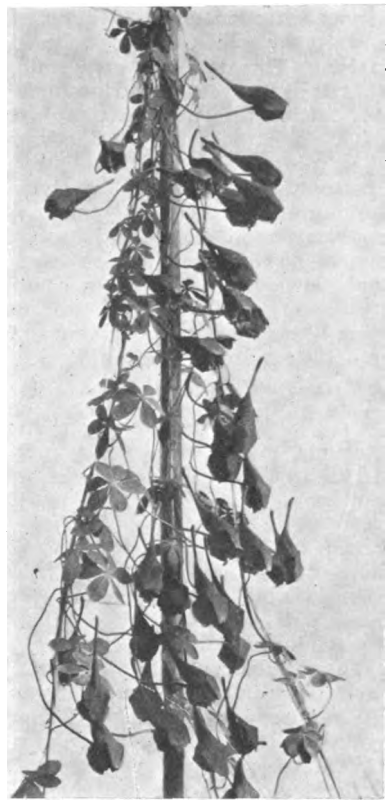
Digitized by Google

is therefore beneficial. The plant, like the others, is of a climbing nature and requires support. It will grow up to 6ft. or 7ft. The yellow and red flowers are rather large. Many of the first season's tubers which are produced by this species are edible, and it is said that these were used for culinary purposes by the Incas of South America, the plant being a native of Peru.

Another genus of bulbous plants which deserves more attention is Brodiæa, the members of which are natives of the western parts of North America, but still tolerably hardy. They all like a warm corner in a well drained, sandy soil, and should be planted late in autumn, covered with 2ins. to 3ins. of soil and from 4ins. to 5ins. apart. Small colonies from twenty-five to fifty plants will give the best effect.

One of the prettiest, but at the same time more tender than the others, is Brodiæa coccinea, the Californian Fire Cracker. This throws up a stem of 1½ft. to 2ft. in height, at the top of which eight to twelve pendulous, tubular flowers are arranged. The colour is shining deep red and edged with green.

Very closely allied are BB. capitata, congesta and multiflora. All have at the top of the stems, which may be about 2ft., crowded heads with many bluish flowers. BB. capitata and congesta, violet-blue; multiflora, mauvy blue. The latter grows somewhat dwarfer. Of BB. capitata and congesta there are forms known with white flowers—offered as var. alba—and generally among seedlings some whites may be found with a lilac flush. If necessary to name it may be distinguished as B. congesta lilacina.



TROPÆOLUM TRICOLORUM.

B. lactea (californica alba) forms an umbel with pretty white flowers, each petal banded with green. B. lactea lilacina is faintly lilac tinged and usually grows 6–8ins. higher, the flower-stems attaining a height of 2½ft.

Very large umbels are formed by BB. Bridgesii, grandiflora, laxa and peduncularis. One of the most decorative is B. laxa with 1½ft. stems and about twenty to forty large purple blue flowers. The umbel may measure up to 8ins. across. B. laxa maxima flowers about a week earlier, and an interesting albino form is B. laxa alba. B. Bridgesii is on the same lines, but with this species the flowers are pinky mauve, although individual plants vary somewhat in colour. B. penducularis is better known, with very large umbels of white and porcelain blue flowers. B. grandiflora, grows very dwarf, with umbels composed of deep blue flowers.

A comparatively rare plant is B. minor. In this species the scape nearly rests on the leaves, which, unlike the others, lie on the ground. The small flowers are pale blue with a deep blue band. This species should have a special position, as close inspection is wanted and the plant has neither stems nor gorgeous flowers to draw attention.

BB. Hendersoni and ixioides splendens (Calliprora lutea) both have on top an umbel with yellow flowers, B. Hendersoni pale yellow, B. ixioides splendens deep golden yellow.

B. volubilis I have not grown so far. It should be an interesting plant, making twisting stems which in nature are supported by herbs or grasses, having an umbel of rose-coloured flowers. It is deplorable that Californian growers or collectors rarely offer a thing new to our gardens. Could a Californian garden friend oblige me with some B. volubilis, or californica, Douglasi, rosea and others not mentioned here? TH. HOOG, JUN.

NOTES OF THE WEEK

PLANTS ON AMBLESIDE.

IT has been my good fortune to spend a fortnight in the very heart of the Lake District. Ambleside was selected as a fit place to spend a short holiday. To the casual observer the English Lakes are always an attractive centre, but to the botanist and plant-lover they offer a land of infinite joy and pleasure. A well known place on Langdales is Steelwith Fold, situated in North Lancashire. My first introduction was to a remarkably fine specimen of Eucryphia pinnatifolia, a plant of magnificent proportions not far short of 30ft. in height and 15ft. through. What is more, it was in perfect health and full of flower-buds. This particular plant has been in its present position for over twenty years. It has received no protection except that afforded by the surrounding trees. There is also a magnificent plant of Notospartium Carmicheliæ. This was a wonderful sight some 20ft. high, covered at the top with what at a distance looked like a wistaria. It was covered with pink or rather mauve-coloured flowers, a perfect picture, and worth a day's journey. A curious plant attracted my attention, namely, a pseudopanax, probably P. lineare, a plant like an aralia, which I had seen before in the Temperate House at Kew. It was interesting to know that it had been growing out in the gardens here for twenty years. Mr. Charles Eley in his book, "Gardening for the Twentieth Century," tells us of his doubts whether the Chusen palm could be rightly included in a list of evergreen shrubs suitable for English gardens. Here at Steelwith Fold, situated among the hills, this lovely palm has found a suitable home. There is a colony of six beautiful specimens, the largest plant being 6ft. high, the smallest over 4ft. They have been in their present position for twenty years. I consider that this palm is quite hardy. One I planted near Southport twenty-five years ago is now in a flourishing condition and produces male flowers, if they may be called by such a name. It stands at present some 12ft. high and is never protected even during the coldest weather. Species of azaleas and rhododendrons assume immense proportions at Steelwith Fold such as one never dreams about in the South. Rare forest trees, interesting evergreen and flowering shrubs all find a good home.—M. H. STENSFIELD, *Southport*.

ROSE GOLDEN EMBLEM.

IT is doubtful if many of the horticultural enthusiasts who attended the splendid exhibition at Shrewsbury made their way to the dell garden in the famous Quarry grounds where the show was held, for the wealth of the exhibits would occupy their time, but they missed a wonderful sight. Here was to be found some splendid beds of roses, the most conspicuous being a large bed of Golden Emblem. Surely there was never anything seen before in such excellence. Tall bushes from 4ft. to 5ft. high were the picture of ruddy health, the foliage as large as holly leaves and the trusses of bloom wondrous to behold. I was informed by Mr. Ward, the able gardener, that when this dell garden was formed quantities of blue clay were used in the making of the beds, supplemented with some good loam. All the fertiliser the plants had received this year was an application of bone-meal. So many rose growers fail with this glorious rose, as they find it dies back in winter, especially after pruning. These plants had been hard pruned, but there was no sign of dead wood. Some of the growths made this year were as thick as a stout walking-stick, and they carried huge bunches of buds and blossoms. I thought it might interest rose-lovers to know of this bed and, incidentally, to encourage those who have failed with Golden Emblem. Evidently the blue clay had worked wonders, and it was a proof that good preparation of the beds before planting well repays anyone.—WALTER EASLEA, *Leigh-on-Sea*.

THALICTRUM DIPTEROCARPUM.

ONE of the obvious plants that should be more frequently grown than it is at present is Thalictrum dipterocarpum. Many nurserymen stock it and it is often seen at flower shows, and yet for some reason or another its popularity has hung fire, and for no conceivable reason. This fine Chinese species was introduced by Mr. E. H. Wilson through Messrs. Veitch a number of years ago, and it is safe to say that no gardener who once grows it will ever be without it again. The flowers of T. dipterocarpum and all the other thalictrums, or meadow rues, have no petals. In their place they have four or

Digitized by Google

five petal-like sepals of a lovely lilac shade tinged with rose. It has been known to reach 8ft. in length, but the normal is about 6ft. The foliage is fine and rather scanty for so large a plant, but the abundance of flower more than makes up for lack of foliage.

There is also a lovely pearly white form called album, but this is rather rare. Farrer always wrote of this plant as being of doubtful hardness, and other writers have followed his lead, which perhaps accounts for its lack of popularity. On the other hand, most gardeners that I have spoken to about it and who know it well are sure of its hardiness, and this is borne out by an American correspondent who wrote of it in THE GARDEN, May 31st, 1924: "It might be of interest to know that this species is perfectly hardy in northern New Jersey, where the temperature has touched zero on several occasions since I planted it three years ago. I have it planted on a north border in medium loam, and give it no protection beyond what other perennials receive, that is, a few old pea boughs, and a little litter."

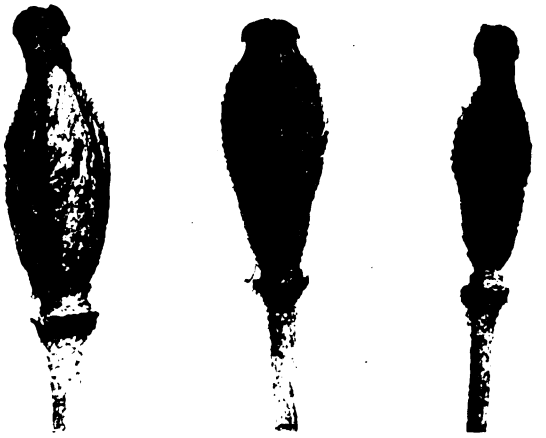
This correspondent grows it in a border, but the best place to see it at its best advantage is the wild garden, where its nodding grace is particularly attractive in July. They are also effective by the waterside. They like a rich loam and sufficient drainage. One reason for their effectiveness by the waterside or in the water garden is that in such positions they do not have to be staked. Their tall stems sway and swing so gracefully that to stake them is the most artificial of gestures.—R. H.

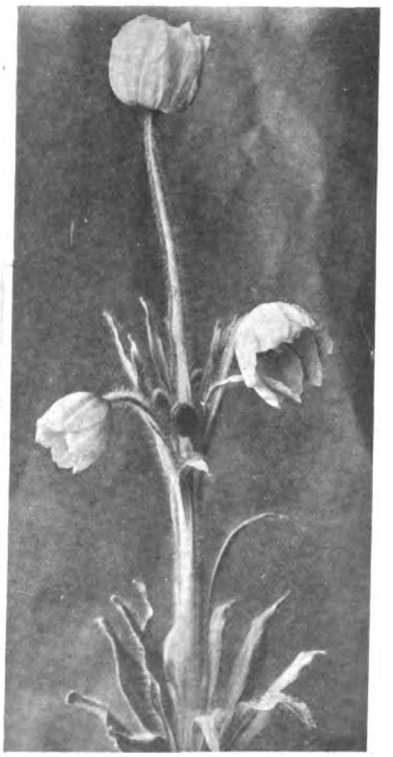
SOME GOOD PLANTS FOR BANKS.

IT is sometimes found to be a difficult matter to select suitable plants for covering dry banks and others that are under the drip from tall-growing and overhanging trees. The double-flowered gorse is a splendid plant for furnishing dry banks in the southern counties. The variety nanus is compact-growing and very dwarf. Gorse plants do not like being disturbed at the roots, but they may be severely cut back when necessary and a dense growth of young shoots will soon appear. The ivies are not grown for bank covering as generally as they deserve. I refer to the large, ornamental-leaved sorts which are pretty on banks near a dwelling house; these, too, may be freely trimmed in due time. The St. John's wort (hypericum), is a splendid plant for covering banks which are in partial shade or under the drip of trees, the variety calycinum, commonly called Rose of Sharon, is the best for this purpose; its flowers, too, are lovely. The variety oblongifolium is a very strong grower and bears very large flowers at the end of summer. I think the best plant for both dry and wet banks, in dense and partial shade, is the periwinkle—vinca. For clothing small banks the variety minor is the best and major the best for big banks. These plants will grow in almost pure sand, and also in a stiff soil; their blue flowers are very charming. Then there are the barberries, those of a spreading or pendulous habit, they should be planted near the top of the bank. For all it is best to form small pockets at first.—G. G.

MECONOPSIS INTEGRIFOLIA.

THE accompanying illustrations show three forms of Meconopsis integrifolia growing in my garden in Perthshire. No. 1 is Meconopsis integrifolia, the flowers of which in a well grown plant measure from 7ins. to 8ins. in diameter, and I have had as many as thirty-eight flowers on one plant. This species comes into flower during the month of April and continues for about two months. This is followed by another variety of integrifolia, which I grow under the name of M. brevistyla. The flowers of these two varieties are very much alike, but there is quite a distinct difference in the foliage, that of M. integrifolia being very silvery, whereas in M. brevistyla it is a brown colour. M. brevistyla comes into flower fully a month later than integrifolia. There is also a difference in the seed capsules, the stigma in integrifolia being much longer than brevistylla. Both of these varieties set a large quantity of seed, which germinates very quickly. The third variety of integrifolia, as can be seen in the illustration, has much smaller flowers. These are much more cup shaped and a slightly deeper yellow colour. This variety flowers at the same time as M. brevistyla, in the middle of May. The seed capsule is not so large as the other two varieties, and I seldom get more than half a dozen seeds from a capsule, some of them containing no seed.—A. HARLEY.





Large Flower. Large Flower. Brevistyla. Small Flower. Small Flower.

VARIOUS FORMS OF MECONOPSIS INTEGRIFOLIA.

FLEAS IN THE ROCK GARDEN.

A FEW weeks ago I was greatly puzzled, and not a little worried by the appearance of four or five plants of Iberidella (Thlaspi rotundifolium), which had, up till then, been growing up nicely on my rock garden. I had planted them out on a tract of limestone scree, where at first they grew well and made good tufts of their characteristic, fat, fleshy leaves; and then something went wrong. The leaves became pitted all over with mysterious little nibblings—not around their edges as any honest caterpillar would gnaw them, but all over their surfaces with evenly peppered little pock marks. For some time I was completely mystified, and could not imagine what was attacking the plants. Not only was it very disfiguring, but it was discouraging. My prosperous plants, which I had expected would smother themselves under pats of lilac honey-scented blossom, became shabby, mangy, unhealthy—growth came to a standstill and it looked as if Iberidella would die. Then, by chance, I discovered the cause. I thought I would gently prod among the scree chips, on the off-chance of turning up some unknown grub or other lurking malefactor, and as I put out my hand to prod, a flea jumped off Iberidella, then another, and another, and another; four or five fleas jumped, in all directions, swift and far—and were gone. I know they were fleas. I have read descriptions of them. But they were not real pukka fleas, such as we have all, I suppose, at one time or another—read of. They were those tiny flea-like beetles known as turnip flea or fly, of which, apparently, there are several species. The turnip flea is well known to kitchen gardeners. He will wipe out whole rows of turnips in the seedling stage, and he attacks the homely Shepherd's Purse and other of the cruciferæ. But that an exclusive little alpine of the upper screes should be infested seemed somehow all wrong. And such a tidy, clean looking little plant too. This adventure with the turnip flea has aroused my interest, and I

Digitized by Google

have been reading up the literature of fleas generally. I find that although fleas and turnip fleas resemble one another superficially, with their glossy bodies and their skill in leaping, they are not really related. Yet there is another trait which they have in common, for whereas I find that the turnip flea has the impudence to forsake his common or garden turnips and attack my expensive high alpines, Bartholomew writing somewhere about 1535 says, "The Flea . . . desireth blood, and doth let them that would sleep with sharp biting, and spareth not Kings, but a little Flea grieveth them, if he touch their flesh."

But the idea of this note is not to show that fleas in Shakespeare's time were as catholic in their tastes as are turnip fleas to-day, but to warn rock gardeners of the danger of turnip fleas among their choice cruciferous alpines, and to tell them how they may get over the difficulty. I am not one to suffer fleas gladly—turnip or otherwise. I do not take them lying down—so to speak. My Iberidellas had come to look like slum poppies, and something had to be done. I bethought me. Then I sent up into the village for a fly paper. This I cut into strips of a few inches, which I spread out neatly all round the Iberidellas, weighted at the corners with pebbles. It worked perfectly. The merry little fleas jumped. They jumped on to the fly papers, and they jumped and were merry no more. Within ten days or so Thlaspi rotundifolium was making a rapid recovery and pushing out a crop of fresh and healthy leaves.

I think it more than likely that other choice small crucifers of the rock garden may be attacked by the turnip flea. In fact, I seem to remember seeing plants of Morisia Hypogæa, with perfectly good roots dwindle away in what I now suspect was a flea-bitten decline.—CLARENCE ELLIOTT, *Stevenage*

THE SEASON FOR EVERLASTING FLOWERS

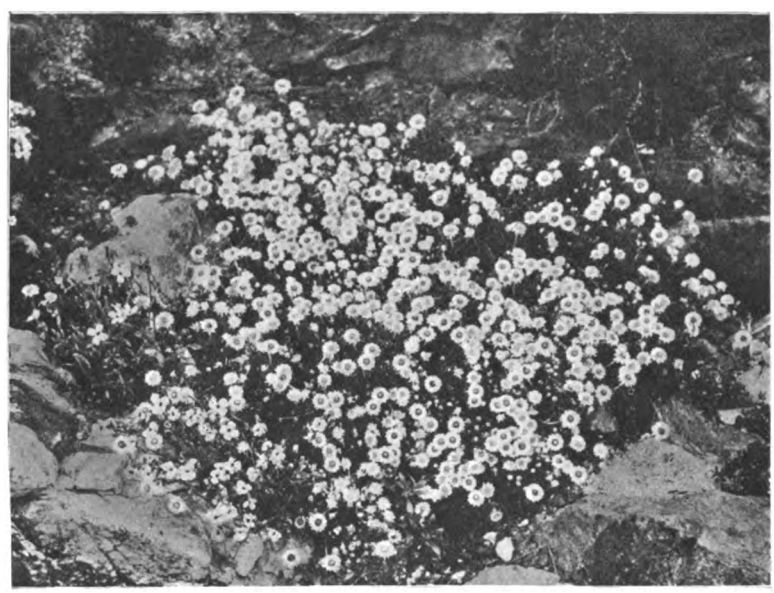
DURING the summer, with its wealth of blossoms in the garden, many overlook the plants that contribute not only to an outdoor display, but have a value for the decoration of the home in winter. It is always a matter for surprise, to me, that so many garden lovers, who have no greenhouse, should attach such little importance to subjects, that after the garden has been bereft of flowers, add interest and pleasure in the embellishment of our rooms. Rarely, indeed, does one find any serious attempt made in growing a representative collection of "everlasting" blossoms, and one wonders, sometimes, whether it is generally known that nearly all the plants are hardy and when once planted will go for years without requiring any special attention. The season for cutting the flowers is here, and these should be placed in vases, without water, the foliage being removed as it shrivels. In Echinops (globe thistles) and eryngiums (sea hollies), we have an assortment of blooms from glistening white to various shades of steely blues. Echinops ritro, with dense blue heads is, perhaps, the best known of the thistles. The stems should be cut before the spiny balls expand, otherwise they do not last long. E. niveus has silvery, globular flower heads and is one of the tallest of the group. E. sphærocephalus bears whitish flowers, and the leaves are silvery.

The sea hollies are a pretty family, hardly so stiff and formal as the thistles. They are ornamental both in the garden and when the bracts are cut for home adornment. E. planum produces in a season quantities of small blue flower heads. E. amethystinum, as its name denotes, yields heads of that colour and the stems likewise, making it a handsome plant. E. alpinum is considered to be the finest of the group, with steel blue heads, devoid of spines. A very attractive one is to be found in E. tripartitum, a very dark blue species, and effective for decoration.

Physalises are perennials prized for the calyces of orange and crimson which are at their best in September. Familiarly known as winter cherries and Chinese lanterns, they add warm colour indoors. P. Alkekengi (orange) and P. Franchetii (orange red), are popular sorts. Statice incana (rosy purple) and S. latifolia (blue), provide spreading heads of coral-like flowers. Gypsophila paniculata, in both the single and double forms, when once established, give us huge panicles of white flowers that last in a good state when cut well on into winter.

One biennial at least serves us well in a collection of "everlasting" flowers. It is highly thought of by many, and lunaria, known to thousands as honesty, gives a quaintness to a room among old furniture. A perennial worthy of mention, but seldom seen to-day, is the blue cupidone—catananche. It loves a dry, sunny position.

Annuals serve our purpose, too; we have them in helichrysums, acrocliniums, and rhodanthes, bearing blossoms of the daisy order, and sprays of statice in colours of white and rose and yellow and mauve. A few sprigs of lavender will provide fragrance in a bunch of "everlastings" which remains long after the flowers have lost their colour. Lightness in a vase of blossoms can be ensured if only some of the fragile looking grasses are introduced, such as agrostis, nebulosa, Briza maxima (quaking grass), Eragrostis elegans and Stipa pennata. Add to these a few sprigs of heather with leaves of bracken when autumn has set its colour seal upon them, and one may have something of interest in the home long after the last of the outdoor flowers have departed.—CLAREMONT.



A GOOD EVERLASTING FLOWER, HELICHRYSUM BELLIDIOIDES.

A ROOM ORNAMENT.

A VERY pretty way of growing date stones is on the following lines: Secure a large sponge and as many date stones as can be obtained. Put the date stones into a jar and cover them with water—rain-water is best. Let the stones soak for the best part of a week. Then loop string round the sponge in such a way that it can be suspended. Soak the sponge well, and then into the openings pop as many of the date stones as can be accommodated. It is well to thrust the stones well down into the interior of the sponge. The sponge can now be hung up in a living-room, and the only thing to do is to keep it moist. It is not long before the date stones begin to sprout. As is well known, the first leaf of the young date palm is a graceful blade of a very intense green colour. Before long the sponge is a mass of the most beautiful greenery. The date seedlings seem to be able to live for months on the store of nutriment in the seed, always providing the sponge is never allowed to become dry.—S. LEONARD BASTIN.

BLUE BORDERS.

LARGE patches of the purple-blue catmint, Nepeta Mussini, are always effective. These regular and opposite clumps of two year old plants, with their numerous stems, are now smothered in bloom. No doubt one year old plants add a little to the floral effect of a border, but in the second and succeeding years the plants are (annually) wreathed in bloom. We usually insert cuttings every year about the end of July, so that young plants will be available to set out in October or early in November, in positions along the front of each herbaceous border.

Cynoglossum Blue Gem is one of the hound's-tongues, and is a graceful and floriferous biennial and worthy of a place in the best borders. It is really well named, as its numerous and dainty flowers give a choice shade of blue. Each June we sow seed on the open border, and in autumn the young plants are transferred to positions set apart for them at the front of the borders. Although some of the stems, when the plants are well grown, reach a height of 3ft. when in flower, they do not look out of place at the front of the borders, as the primal stems are furnished from the base upwards with neat cauline leaves each 2½ins. to 3½ins. long, then in the axil of each leaf is situated a slender shoot, near, and at the end of which the dainty blue blooms are borne. On some of the tall and more robust-growing stems, about twenty flowering shoots may be found, while each plant sends up several stems, ranging in height from 12ins. to 36ins.

The tall and stately Siberian, Iris sibirica, has still many fine and fully developed flowers and numbers of flower buds still to open. It is now between fifteen and sixteen months since one very large matted plant of this iris was torn asunder and the sections set out, several inches apart, to form groups or small colonies on the borders; yet, three months after that drastic treatment, nine plants—out of eighteen in one colony—flowered.

Anchusa italica Dropmore var., standing farther back on the borders, has made a fine display for about three weeks, and will go on flowering for a considerable time yet. Aconitums and delphiniums have opened a few flowers on their stately stems, and these, with the lavender plants, will continue to give shades of blue and purple tones throughout July.—DAVID ARMSTRONG.

TULIP NOVELTIES IN HOLLAND

THE surface of Holland needs no such things as mountains, nor need her chemist shops be filled with Kruschen Salts, so long as she has her tulip fields. A visit to them in company of King Sol has very nearly the same effect on one's spirits as Brindle's famous lemonade at the temperance garden party had on some of its most sanctimonious guests. Her tulip cups are the true "cups that cheer, but not inebriate," and her tulip beds are "bigger by far than the great bed at Ware." Tens of thousands of tulips may lie there and "never feel one another." I drank from those cups and made one more in those beds when the great International Show at Heemstede was literally dying in a blaze of glory—only a week or ten days more of life. I was just in time. The big stocks in the bulb fields had been beheaded, but the lives of the new seedlings had been spared, and I saw them at Haarlem, and Heemstede, and at Sassenheim. What impressed me most, you ask? In a general way, nothing more than the advent of the Mendels and the multitude of late-flowering whites that are all ready to be grown into "stocks." In an individual way, the exceeding beauty of a mass of the lovely rose-pink parrot Fantasy, the refinement of the old Darwin Bleu Aimable as grown in one of those monster glasshouses which are getting all the rage among the growers, and the singular charm of a lovely new white which I was privileged to name White Duchess. This is one of the many that we may admire, but which we must not expect to see in commerce for some little time. If I remember right, there were not more than six or eight bulbs all told, so even if it increases with the rapidity of a Lucifer or a Clara Butt, it must be years before we see it catalogued in our English bulb-dealers' lists. Another of the newest of the new is a very rich, deep yellow named after the late President of the Bulb Growers' Association, J. H. Wentholt. It has yellow pollen and is a grand "laster." It is of medium height. The early bird gets the worm. Mr. Tubergen honours some of his visitors by offering to name one of his seedlings after them, and he gives them the choice of which it is to be. Monsieur Henri Correvon was there the day before me. Well! he supplanted me. He bagged the most beautiful unnamed red in the collection. So what otherwise would have been Joseph Jacob is Henri Correvon. I call it a glorified Scarlet Emperor. All the same, I am very pleased with my pick, which is, likewise, a glorified edition of a very lovely variety, Brightness.

Mongolia and Mme. de Buyssens are two immense pale yellows. The wholesale price of the first named ran into pounds last year, but the figure was as nothing compared with the twenty pounds which the lucky owner got for the first bulb he sold of a fine scarlet named Perseus. Are we in for a big-price era? As far as I can make out, no such prices have ruled either in Holland or in England since the early years of last century, when the famous Fanny Kemble fetched £100, and Louis XVI was listed in Dutch catalogues at £25 apiece. Refulgence is a magnificent big red and Marjorie Bowen a top-hole orange-rose.

I do not expect any of these will be offered for sale this year. As far as I know not one of them is in any of the Dutch wholesale lists for 1925. There are, however, many beautiful novelties that are. Some, now to be mentioned, I hope will figure in our English retail lists this autumn. My two favourites are the pale yellow Arethusa and the bright red Brightness. I have not only seen these growing in Holland, I have had them in my own garden. I can recommend them with every confidence. Arethusa has jumped up very considerably in price from 1924. This is about as good an award of merit as a plant can have. It means that gardeners want it. When Brightness is better known I expect it will have a similar jump.

Alemene is a plant of medium height with a long-shaped rosy-red flower. It received an award of merit in London in May, 1920. I found Rosabella in every one's mouth in Holland, but I was disappointed when I saw it growing. Not so, however, when I got home. My man raved about it, just as they did in Holland. I hurried to see it and then I knew. All I had hitherto seen were Rosabellas on their last legs. In their prime the long rosy-pink petals, with their blush edges, make goodly flowers. I fell down and worshipped at the shrine. I was a fortunate man this year. I hit the late tulips off to a T in Holland. I found mine in quite good condition when I got home. Thus I was able to check my Dutch impressions in several cases. This was especially useful with regard to the whites. I have a few of all the varieties in commerce. Zwanenburg and Carrara are the two best. The first-named is a tall grower, with white flowers of true Darwin shape and black pollen, while Carrara is a dwarfer plant with balloon-shaped blooms and pale pollen. Just as in real life skim milk sometimes masquerades as cream, in catalogues cream masquerades as white. If only the stately Vesta were as pure a white as Zwanenburg and Carrara, they would have a serious rival, but there's that "if." It is striking how orange more or less enters into the colour of many new flowers. It may be no more than a thin wash over the whole, as in the brilliant Darwin Orange Perfection, or it may play a first fiddle part in others, as in Dido, which is a happy combination of rose and orange, or in Ambrosia, which I describe in my notebook as a paler and softer toned Dido, or in Dulcinea, where, however, the rose or cerise predominates. In Aegia it is the same. There is more real rose than orange. The particular charm of this last-named lies in the incurving of its three outer petals, quite in the style of the well known Darwin Euterpe. Just now I seem to have a "rose" wave in my brain, so when I was note-taking, down went the rosy ones, perhaps more often than they should do. The last four are cottage varieties, but it is the same with the Darwins. My notebook records the following as those which caught my eye: Turner (a deep shade), Chant de Cygne (late, soft colouring), Jupiter (not the mauve and violet breeder), Pamela (pale), and Aphrodite. Among the mauve and purple Darwins, Mr. Hoover (pale), Burgomaster Sandberg (deep red-violet), and President Harding (with a prominent pale margin to the petals), are those I noted. In Alaska we have a pretty light looking flower, with rather narrow upright petals—sweet scented and of medium height—of the same delightful colouring as the lemon and primrose mid-season Canary Queen.

Just as what is one person's meat is another person's poison, so in the floral world, what is old to one is very likely new to another. Otherwise how can one account for a dealer's list describing as "new," or a novelty, a variety we seem to remember ever since we were born. It's only a question of relativity after all. So, as a very fascinating little red-toned orange tulip named Marginata which I saw at Sassenheim, was new to me, I include it among my tulip novelties. I call it a jolly little chap. The sort of thing in humans would be described as "always merry and bright." Coupled with this in colour and age there is the breeder or unbroken form of Cherbourg. The broken or striped form used to be one of my garden treasures in prehistoric times, but never until my recent visit to Holland had I seen it as it was when it first started life. It was something to feast one's eyes upon. My old favourites, Prince Albert and Goudvink (Goldfinch), are no longer the "two kings of Brentford on one throne," the throne must be enlarged, for there are now three kings. "And the greatest of these is Cherbourg." There is only one thing against it. It is very expensive, but it thoroughly deserves the first class certificate it was awarded at Haarlem in 1920.

Another "old 'un" nearly related in colour to the three kings, and which I find is gaining favour in the bulb fields, is Garibaldi. A tall, pale biscuit brown, which might almost be described as a Bronze Queen in her more youthful and slimmer days. Every dog has its day. It was Lucifer's day in the rectory garden at Whitewell this year. Never before has it done itself such justice. The catalogues I have consulted agree in calling it an "orange red." This is much too matter of fact for such a grand flower, perhaps some of the "curious" will buy a few and add the necessary garnish for themselves. Lucifer is no novelty, and I do not remember seeing it in Holland. However, necessity knows no law and as I want a good ending, let Lucifer supply the peroration.

JOSEPH JACOB.

CORRESPONDENCE

RHODOSTACHYS PITCAIRNIÆFOLIA.

SIR,—Last year a few correspondents wrote in THE GARDEN referring to the blossoming of Rhodostachys pitcairniæfolia. I shall be interested to know if those same plants are flowering again this year. Of the two plants growing in these gardens, for a number of years, one blossomed for the first time last year. But now both plants are throwing out their bright shining red bracts, and their inflorescences, made up of pale blue tubes and yellow stamens, are fast unfolding.—F. W. RICH, *Elfordleigh, Plympton.*

COLOUR NOMENCLATURE.

SIR,—I think your leader on Colour Nomenclature very timely and very interesting. If a committee of experts met, discussed the matter, and came to a unanimous decision on the various points raised, it would be a very helpful one to multitudes of gardeners and lovers of beautiful flowers and gardens. Very rarely do we find, in the flowers, the various colours given to them in catalogues—I may instance chrysanthemums—except in the case of some of the self colours. One cannot blame those who frame catalogues and describe their goods in them according to their own ideas of colours, but I feel sure that nurserymen would welcome assistance—guidance—in this direction. A subdivision and definite names, as you, sir, suggest, would help considerably, and if those responsible for compiling catalogues followed a lead, it would simplify matters considerably when amateurs are engaged in planting their flower borders and arranging for colour schemes in them.—G. G.

SIR,—I was very interested in your article on Colour Nomenclature in THE GARDEN for September 12th. In the trade, I know, it provides a very big "bone of contention." There are some flowers the colour of which scarcely two persons will agree upon. For instance, take Potentilla Miss Willmott. One big firm describes it as "of a vivid carmine," another informs its customers that it is "of a very delightful rich pink colour"! while yet a third catalogues it as "a charming clear rosy pink" (whatever that means!).

But I fail to see how hyphenated names can be abolished, and for this reason: various plants have flowers which are a combination of colours; the first that I can think of to illustrate my meaning is Viola Mrs. Morrison. This flower represents a conglomeration of at least three shades, *viz.*, ruby, white, and a very dark shade approaching black. The trio tend to make, to my mind, a very beautiful and striking combination, but is it possible, do you think, to produce one word that will accurately describe this blending of colours? There are, of course, countless other plants that would present no less difficult a problem. —J. BIRKENTALL.

SHRUBS IN ARGYLLSHIRE.

SIR,—It is always most instructive to us all to read Sir Herbert Maxwell's interesting letters in your paper, on what can be grown (and is not) in the gardens of the west coast of Scotland, but perhaps he may be a little pessimistic about them, as I know of several, besides the places he mentions, where many good and rare shrubs are cultivated; in fact, most of the Argyllshire gardens have something of more than passing interest in them.

We grow almost every rhododendron, both Himalayan and Chinese, that is worth cultivating. The show of R. Aucklandi, R. Roylei, R. argenteum, R. decorum, etc., this year was gorgeous, but the best of all were R. kewense, which here is far superior to R. Loderi or Loder's White (flowers 4–5ins. across), and R. oreotrephes; the latter Professor Bayley-Balfour considered more attractive than the type, and I have many seedlings of it. The hybrids, R. Gill's Triumph, Beauty of Tremough, etc., were splendid, and *to-day* (September 5th) there is in the woods a Pink Pearl in full flower, also a R. Keysi. Many of the other plants such as Sir Herbert mentions are in full vigour, as also is Cesalpina.

Veronica hedges of all colours are most effective and seed themselves very freely. I have had great success with Eccremocarpus scaber on old buttresses.

Our greatest bugbear is Pernettya, which in our light soil runs all over the place and cannot be checked; that and Spiræa Douglasii are perfect pests. Olearia macrodonta makes a fine hedge, but clipping spoils the flowering for the next year.

In a cold house R. Nuttalli is magnificent, and R. Boothi made a good show this year. Philesia buxifolia has flowered well, and Lapageria rosea is just coming into flower on a north wall. Last year this was most effective in November with the snow on it.—AUSTIN MACKENZIE, *Carradale, Argyllshire.*

THE VALUE OF CLEMATIS.

SIR,—How many people there are—in urban dwellings, at least—who allow "flowerless" ivy and creepers to cover their walls, who might, for a slight expenditure on a few clematis plants, have their walls bedecked with violet, mauve, purple, lilac, crimson and white loveliness for the greater part of the flowering season!

By counting the dead flower-heads as I cut them off, I have kept a record this year of the flowers produced by three plants which I have festooning a garden border. To date, there have been 1,472 flowers, and the plants are still covered with bloom. The three plants referred to were chosen for the test, not because they were more prolific bloomers than others, but because their isolated position made it easier to keep the record. Others, on the house wall and elsewhere in my small garden, have flowered equally abundantly.

In case any of your readers are interested to know the names, the three plants are C. Jackmanii (originally C. Blue Gem, but the graft died down), C. Gipsy Queen (Jackmanii) and Ville de Lyon. The latter has not done so well this year as last, when there was an abundance of bloom, many of the flowers being far finer specimens, both as regards size and colour, than any I saw at the principal shows. The other plants that have done well this year are Mrs. George Jackman and Mrs. Spencer Castle. And Nellie Moser, which, for some reason (perhaps because, like the first three named, it is in an unsuitable position, being in the herb border and subject to much disturbance at the roots), has not hitherto bloomed in the five years during which I have had it, has rewarded my patience this year at last. It has made such vigorous growth that I am justified in hoping that next year it will do as well as any of its fellows.

I hope this letter will influence those of your readers who have not yet introduced the clematis to their garden to do so now. There is no climbing plant better worth while, for few there are that flower for so long a period. And the choice of variety is far wider than my short list shows.—H. R. CURNIN, *Wimbledon.*

ANDROSACES—II

ANDROSACE LANUGINOSA comes from the Himalayas, and is a fine, easy-to-grow species for the rock garden. It is especially suitable for a warm, sunny slope on sandy, well drained soil It is one of the earliest of its family, and throughout the summer it continues to make trailing masses of shining silver, due to the silky white hairs that clothe its leaves, from the reddish trailing growth, abundant heads of pinky-lilac blossoms appear and, usually, a succession is kept up until late summer. Then we have its dainty white variety, quite as charming in every detail, with the same silken leaves and the same amiable habits, but with white flowers, the central eye of which is a greenish yellow and eventually fades to a warm rose colour. Cuttings of these two androsaces may be successfully and readily rooted in sharp sand, when the shoots are young and soft.

ANDROSACE CARNEA is very well known to the alpine enthusiast, and is certainly not very difficult to grow, but with this widely distributed species and its numerous varieties, leaf-mould should be the predominant ingredient in the compost, together with loam and sand. I find that an aspect moderately cool is also more beneficial than one that is hot and dry. It forms tufts of sturdy, deep, vivid green leaves, long and narrow, situated so closely as to present a mossy appearance; its flowers are borne on 2in. stems in the form of an umbel and are of a pleasant rosy-pink shade, with yellow eye. Confined to the Pyrenees, is its delightful variety Laggeri, which is a smaller and denser version. There is also a white variety, alba, which is very sturdy and a good doer, although not too good a white, as may be anticipated. A. carnea var. Halleri is exceptionally good, of robust habit with stiff, erect flower stems, carrying large, very pale pink blossoms, and makes dense tufts of bright green leaves. All the members of this section have hairless glossy leaves, which is a distinct advantage as regards their hardiness in winter. They are satisfactorily propagated by means of seeds and cuttings.

ANDROSACE TIBETICA has a certain reputation, which does not make it a favourite, but nevertheless it is a handsome species and with me it yields readily to cultivation in sandy peat, and the present year one plant, 3ins. across, provided ten noble flower spikes 4ins. high, each with crowded heads of sumptuous lilac blossoms. Its leaves are thick and solid and form lax rosettes, showing short intervals of a deep red stem. Characteristic of this plant are the bracts that sit on the flower spikes, which are on the large side.

Digitized by Google

ANDROSACE CHARPENTIERI.—Of the rarer species, this is one, with small oval leaves bunched together in rosettes at the tip of short, slender stems, the whole plant making a low, rather loose mat. It bears its pink flowers on tiny stalks a quarter to half an inch high, in May. Fine hairs cover the leaves, but are hardly noticeable, except on close inspection, and simply give the plant a smooth, green appearance. A westerly aspect should suit it, in a scree mixture, with an additional sprinkling of chips round the collar,. to run away any surplus water that would be likely to interfere with its well being. Similar in style and habit to this species is—

ANDROSACE WULFENIANA, found on non-calcareous formations in the Eastern Alps. It is a neat and compact, low-growing treasure, forming tufts of small narrow pointed leaves, from which develop the large bright pink flowers. Deep scree treatment is advisable, in which abundant granite or slate chippings are present, in a pocket more or less protected from the hottest sun of the day.

ANDROSACE GERANIIFOLIA is unique, being altogether different from any other in cultivation, but worthy of being grown if procurable. It is a recent introduction from Thibet and is, of course, rare at present, but proves to be easily increased. The leaves are roundish, on leaf stalks 2ins. or 3ins. long, covered with fine, silky hairs, and in general resemble very much those of ordinary bedding geraniums on a small scale, being approximately an inch or so in diameter. It continues flowering all summer, in a most unusual way, making strawberry-like runners 6ins. in length, terminating in an umbel of bright pink flowers. As the flowers die, new leaves arise from the centre of the umbel and form a new tuft, which will, without hesitation, commence to make roots if touching soil. These flower shoots are very plentiful during the season, so that numerous new plants may be had with very little attention. It is of the easiest to cultivate, requiring a simple mixture of loam, leaf-mould and a dash of sand, in a cool, moist position, which may possibly be available at or near the foot of the rock garden on the west side. Also, for a similar aspect in the wall garden it thrives wonderfully well.

LILAC BLOSSOMS OF ANDROSACE TIBETICA.

ANDROSACE PULCHELLA.—As its name suggests, it is certainly pretty, with a light and fairy-like habit, hailing as a new species from China. Leaf-mould and sand are apparently what the plant enjoys, as it is perfectly happy in such. From the old rosettes of tiny glossy green leaves it throws out numerous other rosettes on deep crimson inch stalks, which remind one of Saxifraga brunæfolia, only instead of being long and threadlike, as in the latter instance, they are sturdier and shorter. Its flowers are borne in heads on 1in. stems, in May, and are a cheerful cherry-red colour. Propagation of the species may be successfully effected by taking away the baby rosettes on their short stems and inserting in silver sand in a cold frame, immediately they are available.

ANDROSACE SEMPERVIVOIDES somewhat resembles A. sarmentosa, to which group it belongs, having large, handsome rosettes of distinct leathern leaves, almost hairless, except on their margins, long and oval in shape, tipped with an abrupt small point. The main rosettes throw out several red and glabrous stolons, a couple of inches in length, which eventually end in a new rosette. Its blossoms are bright pink, in heads on short stalks. It is a Himalayan species and likes a moderately cool position, in sandy, vegetable soil. If the runners be pegged down they will readily take root.

ANDROSACE CHAMÆJASME has a wide distribution, occuring in stony calcareous soil and in turf. It runs about freely in ordinary gritty soil, new growths come to the surface from underground stems, and has more or less a straggling habit. The leaves are long, narrow and pointed and combine to form a rosette ; they are slightly hairy, particularly so on the underside, and on the leaf margins they are most conspicuous. Small umbels carry several flowers, white or creamy-white, fading to blush pink as they age, centre eye yellow fading to deep rose.

ANDROSACE OBTUSIFOLIA is very similar in every respect to the preceding species.

ANDROSACE VILLOSA is a charming species from the European Alps, and is easily accommodated in the rock garden, in a sunny, well drained position, in limestone scree or moraine. It makes compact tufts of neat rosettes, enveloped in fine silken hairs of silver. On 2in. stems, heads of solid white flowers are borne in May. It is an extremely satisfactory and pleasing item. A. arachnoidea resembles it very closely, but A. a. superba has a noticeable distinction, in its large and pure white blossoms, almost stemless.

ANDROSACE HEDRÆANTHA is a Balkan species, with long, sharp-pointed leaves of a sturdy and fleshy type, perfectly hairless, of a shining bright green colour. Short stems carry its flowers, which are deep purplish pink. Not knowing its cultural details, I submitted it to a limestone scree mixture, in which it was quite happy. Apparently it enjoys a good deal of moisture throughout the summer, so that the real moraine should be the plant's ideal.

ANDROSACE VITALIANA is also known as aretia and Douglasia vitaliana, and it is quite an easy plant to grow; but, as far as I have seen it is rather shy in blooming in cultivation, although its foliage is so neat and charming that, for that reason alone, it is worth growing. However, the flowers it yields are quite a good change from all others I happen to know, being a bright yellow colour. It makes tufted, short growth, with a distinct silvery margin of short hairs on the leaves. Leaf-mould and sand, in a cool position, suit it well, and although it grows chiefly on non-calcareous ground, it seems to have no particular dislike to a limestone scree. It makes a good subject for a deep crevice and also a wall, where it will make a neat and compact mat. F. BARKER.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants ; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

GARDEN TECHNIQUE

Notes on the Technical Side of the Garden and on the Cultivation of Plants.

ROMAN HYACINTHS.

THE value of the Roman hyacinth as a winter-flowering plant cannot be over-estimated. With the simplest of cultivation it gives its welcome bloom during the dullest days of winter when flowers are particularly scarce. There is no other subject capable of taking its place, my experience of the prepared Dutch hyacinths being that they are at least two months later in flowering. Without a greenhouse or any artificial heat the Roman's delicate and graceful, pure white, sweetly scented flowers may be had by Christmas or earlier. I have had bowls of Romans started in September in bloom as early as mid-November. My method is first to pour an inch or so of water in each bowl, then throw in the fibre to within an inch of the top of the bowl, pressing the bulbs in firmly and finishing off with a little more fibre, leaving the crown of the bulbs just above the surface. Usually no further watering is required until the bulbs are coming into flower; the moisture at the bottom of the bowls soon induces root action and I have not found it necessary to place in the dark. In the moderate temperature of an ordinary living-room the bulbs quickly make growth, and other bowls kept at first in a *cold* room and brought into warmer quarters later provide a succession of flowers lasting two months or more.—P. W.

ERIGERON QUAKERESS.

PERHAPS it is hardly necessary to draw the attention of hardy plant lovers to this erigeron, yet there may be many who have not grown this very beautiful fleabane. If one has only a little of the plant, it should be lifted in the autumn—especially if an increase of stock is required—and the whole separated into single pieces, care being taken to have roots attached to each piece. These should be placed in pots according to the size found most suitable, and then set in a cold frame. By this method one can soon get up a good stock of plants. This year, in the middle of May, we set out several plants, which had been grown for some time in 6in. pots; they were splendidly rooted and in a healthy condition. Two months later they commenced to flower, and kept up a fine display for about a month; and, situated as they were among Giant Perfection ten-week stocks (white), the "very pale lavender pink" flowers, borne on the 2ft. graceful yet strong stems, of this erigeron gave a most pleasing picture of beauty in the corner beds of our flower garden.

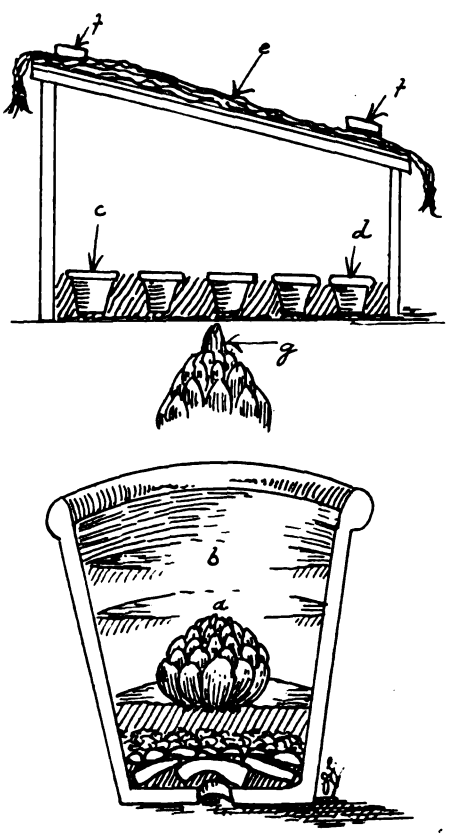
Monarda didyma is a much older and better known plant than Erigeron Quakeress, yet its scarlet flowers add greatly to the picturesqueness of a hardy plant border in the early autumnal days. But, to obtain good results, the plants should be grown in fair-sized clumps in fairly rich soil and in a sunny position. Apart from the usual methods of propagation—*e.g.*, by seed and division of the roots—this bergamot can easily be increased by cuttings.—DAVID ARMSTRONG, *Midlothian*.

GRAPES AND PEACHES AFTER FRUITING.

I AM sure that many readers of THE GARDEN who are fruit growers have suffered from peach tree buds dropping in spring just when they are looking forward to having sheets of blossom and, eventually, highly coloured fruits, or, in the case of grape vines, to still better crops in the future. Both kinds of fruit trees require rest during the winter months and also a border consistently moist. To ensure a nice moist condition of the border soil the drainage must be perfect. Blocked or otherwise imperfectly drained borders should be attended to during the autumn months. There is no more suitable time for such work to be done. If the drainage is satisfactory, the border soil should be watered at such intervals as will ensure it being kept nicely moist right down to the drainage material. Too often the borders and the trees are neglected after the fruits are gathered. A check is given to the flow of sap, after the period of rest the sap moves again and the buds, already loosened on the twigs, do not benefit, they drop off. Plenty of air must be admitted to the trees and their shoots duly thinned where necessary and tied in at a minimum distance apart of 4ins. If the soil is lacking in lime, add the latter in the form of a surface mulch. In numerous cases pot plants are grown in vineries, and, while they require a little heat, the vines need rest. Frost will not harm the rods under glass, and if they can be kept as cool as possible and quite dry till February or early March, the buds will grow kindly and strongly. Do not peel the rods, only remove loose bark. Finally, prune them late in December.—GEO. GARNER.

POTTING LILIUM HARRISSI FOR FORCING.

ALL tall-growing lilies are stately and the pure white-flowered ones are exceedingly chaste in appearance and always appreciated when forced. Whether three bulbs or three hundred are potted with a view to forcing early growth, the same treatment is necessary. Liliums will not thrive in a badly-drained border nor in a flower pot when the drainage is defective. Maiden loam, fibrous, cut and heaped for about six months form an ideal



compost if some well rotted manure and a little sweet leaf-soil be added. The bulbs should not be exposed to the air very long—only a few hours at most. When received from the bulb merchant do not remove them from the packing material and lay them on a dry shelf, but have the potting compost ready for use, also clean, dry pots and crocks. Very carefully examine each bulb and remove any decaying scales found, before potting, as one rotting scale may cause the whole bulb to decay. For understanding the details of potting we may look at the sketches. On the crocks there is a layer of rough compost, the bulb being placed on this as shown. At *a*, some sand is laid, covering lightly the crown of the bulb. Later, more compost is added, shown at *b*. According to the size of the pot the bulb suitable may be used, the largest to the smallest, as *c* to *d*. The covering mat *e* is kept in position by wood blocks, *f*, *f*. The pots may be placed in a bed of ashes, but not covered; the new flower stem, *g*, should be watched from time to time. Remove the mats when growth is free. Do not attempt forcing before the pots are filled with roots.—G. G.

FRUIT TREES IN POTS.

IN many gardens where greenhouses exist accommodation could easily be found for a number of fruit trees in pots, and for the majority very little fire heat would be required. Now is a good time to select the trees, and it is possible to secure varieties characterised by their reliable cropping, and good flavour, while our leading nurserymen can supply excellent specimens suitable for pots.

Peaches and nectarines are, perhaps, more largely grown in pots than any other fruit, and a grand pot variety for early work is Hale's Early, while Duchess of Cornwall is also a fine early kind. Other suitable varieties include Stirling Castle, Early York, Dr. Hogg, and Dymond. Among nectarines will be found Cardinal, Early Rivers, Lord Napier and Victoria. During recent years plums have been grown more freely in pots under glass, where it is possible to protect the fruit until it is fully ripe for dessert purposes. The gages are first rate, and such kinds as Jefferson, Allgrove's Superb, Kirke's and Coe's Golden Drop, are all reliable. Cherries are ideal for pots, neither do they require much root space. A few good varieties embrace the Duke section, Early Rivers, Emperor Francis and Noble.

Pears are not grown in pots to any great extent, and if apples are included in the list, only the choice varieties ought to be grown. Trees, two or three years old, are the best, and whenever possible they should be purchased already established in their receptacles. If not, they can be placed in pots 10ins. or 12ins. in diameter, and then plunged in ashes to the rims. Moderate drainage is needed, over which is arranged a piece of turfy loam to secure a free outlet for water. A medium heavy loam forms a suitable rooting medium to which is added a liberal sprinkling of old mortar rubble put through a half inch mesh sieve. Make the soil firm about the roots. No trees ought to be forced until they are well established in the pots.

ROSES ON THEIR OWN ROOTS.

WE are so accustomed to the rose being budded on the briar, that probably few give a thought to roses on their own roots. Probably the weaker growing varieties require the support of the briar roots, but there

Digitized by Google

are others that thrive equally as well without their assistance, and, moreover, we are not troubled with suckers which often take the lead in an amateur's rose border.

The rambler section is admirably adapted to this method, and the cuttings readily form roots about this period of the year. American Pillar, Excelsa, etc., thrive immensely, and push up annually a number of stout, healthy shoots. Another rose is Paul's Scarlet Climber, of which we have raised some hundreds from cuttings. In addition to covering poles, it makes a useful bedding rose on its own roots, the young growths being pegged down early in the spring and most of the old wood removed. It is also excellent as a pot plant. Nearly all kinds of hybrid perpetuals root freely in the open, while the teas are best accommodated in a frame or hand light. The climbing varieties of Caroline Testout, Richmond, etc., are all doing well on their own roots, and this remark also applies to the single varieties of which the Irish Elegance class may be cited as an example.

Cuttings are made from wood that is getting firm, and not too sappy, such as the lower portion of a shoot which has flowered. The cuttings should be about 6ins. or 8ins. in length, the lower leaves are cut off, and shoots ought to be planted firmly 4ins. deep. A partially shaded border is chosen, and if the soil is on the heavy side, a liberal sprinkling of sharp sand will be necessary. A distance of 1ft. is allowed between the lines, and half that space in the row of cuttings. Here they will remain till next autumn, when they can be transferred to their permanent quarters.—T. W. BRISCOE, *Chepstow.*

WINTERING SPECIMEN LAWN PLANTS.

SPECIMEN plants increase in size every year, and room must be found for them during the winter, as, obviously, they cannot be left outside. But where glasshouse room is limited, the largest of some kinds can be wintered without its aid.

Scores of plants are used as dot plants in borders over low-growing subjects. The majority of these are retained in pots, the latter being buried to their rims in the border soil. Now, these plants are more easily dealt with than others that have to be lifted and potted, but, all the same, to enable them to overcome the check, it is the better plan to place them on the north side of a wall for two weeks prior to transferring them to the greenhouse. Fuchsias, heliotrope and similar subjects need this treatment, and fine-foliaged plants a little shading from bright sunshine for ten days. Keep the greenhouse rather close for the same time, then ventilate freely on fine days. Zonal and ivy-leaved pelargoniums must be wintered under glass; but after due preparation fuchsias, hydrangeas, sweet-scented verbena and similar plants may be stored safely in outside sheds if the pots are well packed in dry litter.—G. G.

THE ODD CORNER.

I THINK we all find odd corners in our gardens; sometimes they are passed by quickly because they are not interesting. But why are they not interesting? Because the little trouble to make them so has not been taken. The present is a suitable time to attend to such corners. Many lovers of gardens like special kinds of flowers, bulbous or fibrous-rooted; some prefer uncommon common flowers, and some hybrid berried fruits. In all cases it should be decided at an early date to tackle the odd corner. It may be that plenty of weeds abound there; if so, uproot them and destroy them by fire, also all foreign surface matter. If the soil is well permeated by the roots of coarse weeds, it should be deeply trenched and the roots got rid of. To sweeten and improve the soil add lime to it, leaving the whole in a lumpy state for a short time. A single loganberry plant will soon fill up any such odd corner. If open to the sun, not unduly overshadowed by the branches of tall-growing trees, the corner may prove to be an ideal one for a garden frame, and, certainly, such corners are often very suitable for nursery beds wherein to raise violas, wallflowers, polyanthus, primroses, hardy primulas, giant-flowered daisies, arabis and similar spring-flowering plants, so that the neglected bit of ground will soon become a source of pleasure and profit too.

BULBOUS PLANTS SUITABLE FOR THE ROCK GARDEN.

IN this group will be found a large number of beautiful plants that should find a home in every rock garden, and when planted in pockets or among some of the low-growing subjects they afford much interest and pleasure at a period when flowers are none too plentiful.

The daffodils of the smaller flowering or miniature varieties are excellent, and in no position do they look better than when growing through a carpet of some creeping rock plant. Narcissus cyclamineus, N. minimus and N. triandrus can be recommended. Chionodoxa Luciliæ is a charming plant, growing about 6ins. high, with deep blue flowers shading to white in the centre. A bold clump is most effective in early spring, and other forms of chionodoxa are also worthy of consideration. For giving a touch of brilliance Anemone fulgens should be chosen; its vivid scarlet flowers appear in April, with occasional blooms at other seasons. A large mass is a fine sight. It enjoys a partially shaded spot, where the soil is good and rather moist.

Good varieties of the wood anemone (A. nemorosa) are suitable, also A. baldensis and A. apennina.

The dwarf kinds of iris are almost indispensable for the rock garden, and the violet-scented I. reticulata with its dark blue flowers is one of the best. I. gracilipes, I. cristata and other dwarf forms are all suitable for the rock garden where the soil is light and the position not heavily shaded.

Tulips are well known, but there are a few choice species well adapted to our purposes, such as T. Greigi (orange scarlet), T. Kaufmanniana (white, orange and red) and Eichleri (scarlet). Snowdrops and scillas in variety, and, for autumn flowering, the bright golden yellow Sternbergia lutea, should be planted; also Colchicum autumnale, ixias and sparaxis can be obtained in striking and beautiful colours, and will prove a notable success if planted in masses at the back part of the rock garden. Crocus, erythronium, allium, Fritillaria Meleagris and Muscari ought to be represented, either on the rock garden or in the immediate neighbourhood.—T. W. B., *Chepstow.*

FORCED FRUIT IN THE EIGHTEENTH CENTURY.

THIS year our peach and nectarine trees have borne splendid crops of richly coloured fruits, and it may be worth while mentioning that a garden in the same county—and only a mile or so distant from where the writer lives—gained distinction over 160 years ago for the choice peaches and other fruits which were grown there under glass.

The writer of the book "Craigmillar and its Invirons" has stated that from "1760 to 1785 the garden at Moredun (Midlothian) claimed pre-eminence as being the richest in the county, and it was believed to be the first in which forcing was carried out to any degree of perfection. Baron Moncrieff, the proprietor, used to boast that from his own ground within a few miles from Edinburgh he could, by the aid of glass, coals, and a good gardener, match any country in Europe in peaches, grapes, pines and every other fine fruit excepting apples and pears. These, he acknowledged, were grown better in the open air in England and north of France." These remarks serve to show that the peach, like the vine and the pine, received ample care and attention from the fine old horticulturists of the past.

Two hundred feet or so of the glass structure in which the peaches were grown at Moredun is still standing, and in a fairly good state of repair. It would have been very interesting to know the varieties of peaches grown at that period, but of this there is no record, so far as I know. Perhaps the very old variety, Royal George, would be among the number, as it is stated in M'Intosh's "Practical Gardener" "to be of French origin and was introduced to this country at or before the beginning of last century, as it is mentioned by Powell, gardener to George the Second."—DAVID ARMSTRONG.

[*This is the second instance lately of the mention of glasshouses standing for a century or more. It would be interesting to know if there are many glasshouses in existence in the country known to be over a century old. Perhaps readers could supply details of other examples.* ED.]

AUTUMN ROSES AT REGENT'S PARK

THE day when roses were specially named on account of their blooming during the autumn is now long past, and it seems as though most of our present-day garden roses flower as well in the autumn as in June and July, so that we went to the autumn show of the National Rose Society at Regent's Park on September 17th and 18th in the full expectation of admiring roses in quantity and of high quality. Nor were we disappointed, for there was an abundance of most delightful blooms to be seen, and if they lacked, perhaps, a little of their summer fragrance, they seemed to have gained in delicacy of beautiful colouring, although towards the end of the first day and during the Friday the genial warmth of the tents induced a most pleasant perfume. Following a wet afternoon, the warm but not too bright weather was ideal for a flower show, so that there was a large attendance and the blooms continued fresh and attractive.

As ever, the new seedling roses were the first consideration of a large number of enthusiasts, and long before noon there was the customary queue waiting to enter. There was an unusually large number of entries, and while all these seedlings possessed distinct attractions, only seven were singled out by the council, who awarded three gold medals and four certificates of merit.

Of the unfortunate varieties there were some we much admired, though, at the same time, we felt that the council had, no doubt, exercised a wise discretion in limiting their awards. John Henry, shown by Messrs. George Beckwith and Son, is a rich pink hybrid tea rose of distinct type. James Faris, one of Dr. Campbell Hall's seedlings, is a very large hybrid tea bloom, fully double and of very pale lemon shading, and of considerable merit as an exhibition bloom,

Digitized by Google

though we suspect it to have rather too weak a stem for everyday use. Lady Florence Strong was among the unfortunates in only a degree, in that this delightful rose, which Messrs. McGredy and Son describe as reddish prawn shading to violet rose, with yellow at base of the petals, has already received a certificate, but did not gain the gold medal. Still, it is a most charming bloom of very fascinating colouring. Marion Cran, another of the McGredy roses, is flushed with orange scarlet on a golden ground.

The medal rose in the nurserymen's classes was a gorgeous bloom of H. V. Machin shown by Mr. C. Gregory; while with a vivid specimen of J. G. Glassford, Mr. J. N. Hart won the amateurs' medal. The Clay Challenge Vase, which is annually offered for the best new rose of the year, was awarded to the richly fragrant dark crimson Arthur Cook, which won a gold medal at the provincial show at Bath.

The large groups of representative roses continue to be popular with the exhibitors, and there were no fewer than nine in the large class, while the other two were also well filled. Although these exhibits contained generous quantities of excellent roses, there was a great sameness in the styles of treatment; nearly all the exhibitors filled their space with pillars of roses surrounded by baskets and vases. We appreciate the difficulties attendant on any departure from the conventional arrangements, but we are confident that the exhibitors possess ample skill and taste to break away and so add variety to their handsome collections. In Class 12, which required thirty-six distinct varieties of miscellaneous roses, Messrs. A. Harkness and Co. evolved a new and particularly charming method of treatment and received their due reward of the first prize.

In the principal group class Messrs. S. McGredy and Son were first with pillars and baskets of gorgeous blooms of Mabel Morse, Betty Uprichard, Golden Emblem, Mrs. H. Morse, Independence Day and similar beautiful roses. This was edged with polyantha varieties; while Mr. Elisha Hicks edged his adjoining second prize group with an attractive collection of rose hips. His chief varieties were Ophelia, Sunstar, Betty Uprichard and Joanna Bridge. Messrs. A. Dickson and Sons were third, and Messrs. Chaplin Brothers were fourth in this large class.

In the class for a slightly smaller group Mr. C. Gregory was first with an arrangement of corner pillars of roses arched to a centre of good blooms over a massed groundwork. Messrs. Prior and Sons, who were second, and Messrs. A. J. and C. Allen, the third prize winners, both had very good collections

Mr. G. Prince had a very pretty display of baskets and vases of La Tosca, Mr. H. Stevens, Hadley, Golden Emblem and Shot Silk in his first prize 6ft. square group, where Mr. W. Bentley was second and Mr. J. Mattock was third. The eighteen varieties of decorative roses were of high merit, and Messrs. Chaplin Brothers included beautiful blooms of the Rev. F. Page Roberts, Duchess of Wellington, Frau Karl Druschki and Butterfly. Mr. George Prince was a good second, and Messrs. Morse Brothers were third

The baskets of roses were not so numerous as usual, but Messrs. Chaplin Brothers had lovely blooms of Betty Uprichard, Mrs. Tresham Gilbey and Ophelia among their five first prize baskets; while Mr. H. Drew was second. The best three were of Lady Pirrie, Mrs. Henry Morse and Mme. E. Herriot, shown by Messrs. T. Smith and Sons; while Messrs. D. Prior and Sons had a beautiful basket of Ophelia in their second prize exhibit. They were first with Kirsten Poulsen, Alice Amos and Else Poulsen, three lovely baskets of polyantha varieties. Mr. C. Gregory had the three best baskets of exhibition roses; his varieties were George Dickson, Florence Forrester and Frau Karl Druschki.

LADY F. STRONGE, A HYBRID TEA OF UNIQUE COLOURING.

With exhibition roses the chief honour fell to Mr. A. (Sandy) Dickson, whose very good twenty-four varieties included Lady Moreen Stewart, Clara Curtis, Oliver Mee, Gorgeous and The General. Mr. C. Gregory was second, and he had fine blooms of J. G. Glassford, Admiration, Florence Forrester and Mrs. G. Marriott. The exhibits of eighteen exhibition varieties were also of considerable merit. Mr. George Prince won the first prize with such sorts as H. V. Machin, J. G. Glassford, Frau Karl Druschki and George Dickson. Messrs. H. Lane and Son were second, and Messrs. English and Son were third.

Tea and Noisette roses were very fresh and good. Mme. Cochet, A. H. Gray, Auguste Comte and Muriel Wilson, in Mr. Prince's collection of varieties, were very beautiful. Mr. H. Dreer, who was second, had good blooms of Marie Van Houtte, W. R. Smith and White Maman Cochet.

AMATEURS' ROSES.

The competition in the amateurs' classes was particularly good, and the quality of many of the blooms rather surprised the trade growers. This was particularly so with their vases of decorative roses, where Mr. S. W. Burgess won the first prize with excellent vases of Ophelia, Sunstar, Betty Uprichard and other valuable sorts. Mr. T. C. Wiseman was a very good second. Mr. A. L. Cook also staged admirable vases of decorative varieties, his examples of Betty Uprichard, Emma Wright and Ophelia were excellent; while in the class for amateurs who grow their roses unaided, Mr. S. E. Tattersall had equally meritorious blooms.

The exhibition roses were of equally high quality, and among the first prize winners were Mr. J. W. Hart, Potters Bar; Mr. H. Mitchell, Bradford; Mr. R. de V. Pryor, Hitchin; and Mr. J. Tiller, West Drayton, who had admirable exhibits.

The best roses grown within ten miles of Charing Cross were shown by Mr. A. N. Rogers of East Putney, who also was the chief winner in the five miles radius class. He showed good blooms of Constance Casson, Mrs. H. Bowles and Mrs. George Marriott. Tea roses were of even better quality than in the nurserymen's classes, and Mr. W. E. Moore had delightful specimens of W. R. Smith, Lady Plymouth, Mrs. E. Mawley, Mrs. H. Stevens and Auguste Comte. Mr. Moore also had the best six blooms in the class for pure amateurs. This class was especially popular with exhibitors, and contained many particularly good blooms. Mr. A. M. Darling, Tonbridge, had an especially good exhibit of George Dickson, J. G. Glassford, H. V. Machin and Frau Karl Druschki.

The many dinner-tables were very attractive and in the open class Mrs. A. Tisdall was first with a charming table of Ophelia, and she also had the best bowl of roses. The first prize amateur table was a charming arrangement of Roselandia by Mrs. Courtney Page; and Mrs. Oakley Fisher was second with the same variety. Mrs. Page was also first in the two classes for bowls of roses; while Miss M. E. West had the best vase.

NEW ROSES.

ANGELE PERNET.—This is one of the novelties that has already received a certificate of merit and now gets the highest award. It is a typical Pernettiana seedling, with neat shining leaves, fairly numerous spines and beautifully coloured flowers. At the French rose trials at Bagatelle it aroused the enthusiasm of all the specialists and was there awarded a gold medal. It is a well formed bloom carried on long stalks, and the colour may be described as a coppery orange flushed with pale peach pink on the insides of the petals. Gold medal to Messrs. George Beckwith and Son.

DESMOND JOHNSTON.—The blooms were scarcely open enough, but when more advanced it should be a very fascinating rose. It is a long-stemmed shapely hybrid tea bloom of the type favoured by the market-men, and added to this is a vivid scarlet flushing on a golden base. The purplish foliage is firm and clean. Certificate of merit to Messrs. S. McGredy and Son.

GOLDEN GLEAM.—A very vigorous variety, throwing up stout purplish stems which carry large perfectly shaped, rich yellow blooms which have the outer petals delicately stippled with rose pink. Certificate of merit to Messrs. S. McGredy and Son.

A REQUEST

A FEW weeks ago I wrote a short paragraph called "A Request," in which I asked readers to send any notes on their plant experiences. This small suggestion has borne fruit amazingly. A number of exceedingly interesting notes are being sent in; in fact, those that have had to be discarded are surprisingly few. Some of these notes have already been published, others are being held over until they become topical owing to the approach of the planting or flowering periods of the plants they deal with. In all cases our readers are enthusiastic. One note had the following letter attached:

> "The suggestion the other week about gardeners sending in notes, either long or short, is just the very thing for horticulturists to take up. It brings out new talent which, for want of courage, has been lying like a dormant or latent bud, waiting to be encouraged to burst. I wish the idea all success."

We do not claim this idea to be a new one, but we do claim that no other paper has fully realised the possiblilties of using its columns to such an extent for exchange of those little extra bits of information which often mean so much to the successful cultivation of all plants. We ask you all to help your fellow gardeners by sending in notes of successes and failures.

FORCING

On another page in this issue will be found the first half of an article on early vegetables by Mr. Edwin Beckett. In it he points out very wisely the fact that many more early vegetables could be grown at home—and the same applies to flowers. This is a point on which I feel very strongly. We are told on all sides that it is necessary to restrict our imports, particularly from foreign countries, as apart from Colonies. It is certain that an enormous sum of money is sent out of the country every year to such early fruit and vegetable centres as France, Spain and the Canary Islands, in return for our supplies of early or out-of-season vegetables and flowers. Of course, it is impossible for every gardener to aim at growing his own early supply; many of them have not got sufficient accommodation, but it is the duty of every gardener to utilise what empty space he can for forcing and the duty of every owner to see that this is done. There is little doubt that most glasshouses and frames, large or small, are used at the present time in a most haphazard manner. Everyone knows that they are costly to erect and even more costly to keep up, and yet there is far too little method about their use.

As Mr. Beckett points out, much of this early forcing would utilise space and material which would otherwise be lying idle. If a little ingenuity is exercised, it means no added fuel consumption, which is the greatest expense in winter. It certainly means a little more labour, but that is not an impossibility.

I have no figures before me about the heavy importations of early forced vegetables and flowers, but they must run into many hundreds of tons, costing many thousands of pounds. At the best the demand for out-of-season produce is an exotic growth, but it is a sign of the times. If we feel that we cannot do without new potatoes in January and strawberries in the spring, we should, at any rate, see that they are home grown and that money is not going out of the country for what, after all, is an unnecessary import. Every gardener and every garden owner who can spare the space, should give very serious thought about supplying at least a portion of their household requirements of early flowers and particularly of early vegetables.

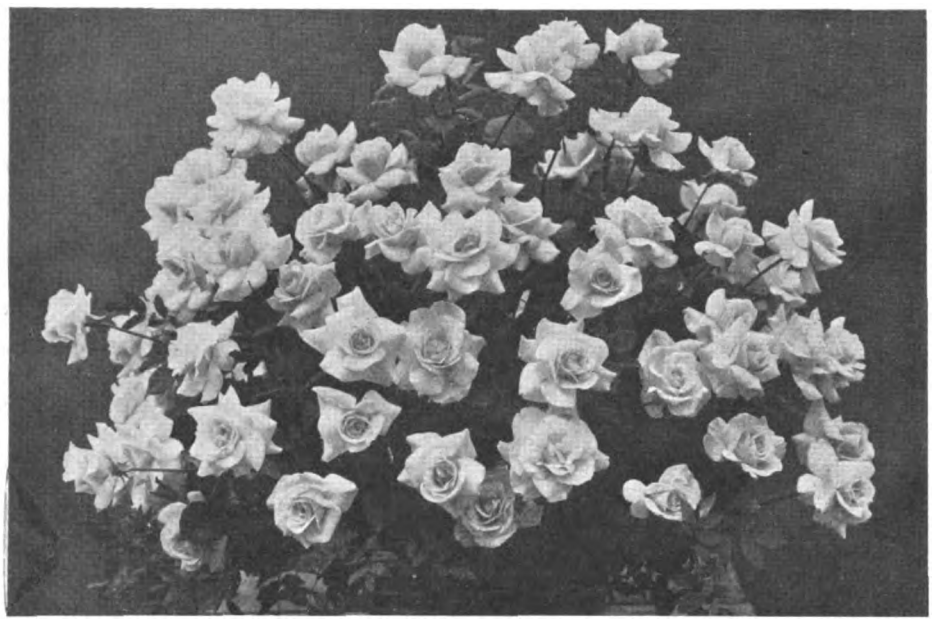
FLOWERS IN VASES

There is much to be said in favour of the increasing number of classes devoted to decorative vases and bowls in flower shows, for it is obvious that we see as much, if not more, of flowers in house decoration as we do growing in the garden. Usually the quality of flowers seen in these classes is excellent, the same cannot often be said of the arrangement. Perhaps this is hardly fair criticism, for what looks well in the house may not have the same appearance on the show bench; but the judges should make some allowance, for, presumably, the class is arranged to show the value of the particular flower for cutting and ordinary indoor decoration. The usual fault found with such exhibits is that the vases and bowls are too crowded.

Arrangement of cut flowers can be divided under three heads—the Japanese, the average, and the mass arrangements. The Japanese is the simplest and the most difficult, for success is attained by beauty of form with hardly a thought as to colour. This means that the receptacle and the plant must make a combination in grace, and that the flower or branch must be chosen for the vase or bowl, or the vase or bowl for the flower. This is difficult at all times, and impossible when you have small choice of receptacles. This style of arrangement looks out of place in a room which is crowded with furniture and crammed with knick-knacks. It looks charming in a room that verges on the austere.

Digitized by Google

The second or average class is the commonest and most satisfactory, for it depends on variety and the clever use of contrasting colours, shapes and sizes. It is the product of a half-hour walk round the garden picking here and picking there and collecting a posy. Everybody has their own preference of colour schemes, but form is often wanting in the arrangement of vases. Some flowers seem to fall into a natural grace when placed in a vase, others have to be coaxed and petted into position. Natural taste must predominate, but vases should never be overcrowded. One point is often overlooked, and that is that vases should be in a certain ratio to the height and size of the flowers. Large-headed flowers should never be arranged in vases with a narrow top however tall they may be, and the opposite is just as true. In the same way tall flowers look overladen when shoved into a dumpy vase. The use of a vase of wrong shape or size intensifies any shortness of stem due to drought or an error in cutting. The shape of the vase and bowl is also of importance, and the more they rely upon grace of line and the less on external decoration the more useful they will be found. There is a happy mean which is perfect and is easy to attain once your attention has been drawn to it.



A MASSED ARRANGEMENT OF ROSE MADAME BUTTERFLY AT THE AUTUMN ROSE SHOW.

The third class is the massed effect, when dozens of blooms of one particular plant are massed in a bowl or a large vase. This only looks well in a heavy room which is already crowded and is, indeed, necessary, for slimly built arrangements are rather lost in a crowded room. The disadvantages of this type of arrangement in an ordinary house are several. The chief one is that it is next to impossible to prevent a massed effect from looking overweighted and heavy. It may give you a blaze of colour and a fine colour effect, but it is unnatural; also in the ordinary garden it is often difficult to pick masses without leaving the bed or border rather desolate. Surely the joy of vases of flowers is to bring a little of the atmosphere of a garden into the house, and this can best be accomplished by making your arrangements as natural as possible. Give a little study to the form and shape of a flower and try to evolve a scheme which will show off the natural beauty to the greatest effect.

E. H. M. C.

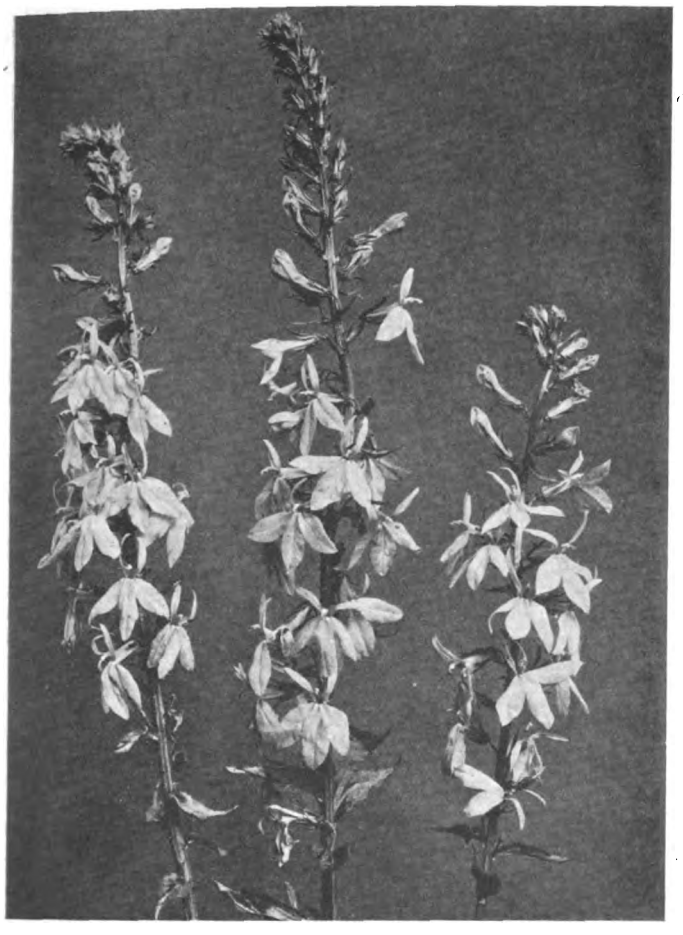
PERENNIAL LOBELIAS

"SURELY *that's* not a lobelia," said an old friend to me when I pointed to a bunch of the new Purple Emperor in Mr. B. Ladham's interesting group in the Hall on September 8th. His remark only showed that, like a good many more, he was not aware of what was going on among the perennial lobelias. The multitudinous garden varieties of L. Erinus (the indispensable blue in Victorian "bedding out"), and even the totally distinct fulgens variety, Queen Victoria, with its tall spikes of rich red flowers, may be said to belong to that well known omnibus group of plants entitled "Too well known to need any description." But this rich purple hybrid, that pretty blue species syphilitica, and that dark-leaved magenta—well, nearly magenta—Ladham's "latest out," Kimbridge, are all so upsetting to ideas based on knowledge of the ancients only, that one feels that the new colours and the increased hardiness of these little-known perennials ought to be made more widely known. As a matter of history, Mr. Ladham is not the first person to use syphilitica, which is the species which has made these changes by giving these new colourings and this greater robustness to the race. In or about 1895 hybrids between fulgens, Queen Victoria and syphilitica were put into commerce by the French firm of Rivoire Père et Fils of Lyons. Whether these are still to be had I cannot say; nor yet whether any of these are identical with those now offered by Ladhams. It is sufficient for us to know that the English headquarters for these new lobelias is the aforementioned firm of B. Ladhams, Limited, of Southampton, and that, if anyone wishes to see to what perfection the plants may be brought by proper cultivation and a situation to their liking, the goodly sight may be seen in Mrs. Humbert's garden in the little village of Kimbridge.

It was a tiresome job to lift and keep the old Queen Victoria through the winter. The hybrids with syphilitica blood may be left where they have bloomed, all winter, and divided into single crowns when growth commences the following spring. The exact time varies in different localities. Division must not take place until the cold and drying March (?) winds are over. They then require no lifting and potting. They should be planted at once in their flowering quarters. This annual lifting and dividing is not an absolute necessity everywhere; but as with tulips, so with these lobelias, it is quite the right thing to do. Rich soil is a *sine qua non* if fine spikes are to be had. Plenty of moisture during their period of growth is also requisite for their highest development. Given these, along with timely staking, if the situation is windy, and a delightful display in early September is assured. Fine bone-meal and a touch of superphosphate of lime may be added when the beds are being prepared. Of course, they may be planted in clumps in borders just as well as in beds by themselves or in combination with something else. I remember so well seeing a most happy arrangement in a Staffordshire garden not long before the war. The centre was either Firefly or Queen Victoria with an outer circle of finely flowered Salvia patens. The rich blue of this last-named made an ideal setting for the taller lobelias.

The different hybrids vary considerably in their heights and manner of growth. Some put forth a good many side shoots, while others have practically none. I have never had the courage to pinch out the main shoots of these branches, but I feel convinced that it might be done if a later bloom than normal is wanted,

Digitized by Google



THE PERENNIAL LOBELIA—B LADHAMS—A HIGH-WATER MARK AMONG SYPHILITICA HYBRIDS.

or if necessity has made the planting out more sparse than future developments show that it ought to have been. In other words, a given area may be covered with a fewer number of plants should this be done. Normally, a space of from six to nine inches should be left between each at planting time. There are not at present a large number of varieties in commerce—probably not more than a couple of dozen, including syphilitica and s. alba, and also Queen Victoria and Firefly, which are of the fulgens type. I have no doubt about my favourites. One is the grand B. Ladhams, a bright scarlet with green foliage. I think Mr. Ladhams himself thinks this is his show child, for when I asked him which variety he would like to have photographed he at once said "This," pointing to B. Ladhams at the same time. I couple with this Shirley Beauty. It is a plant of a deeper dye altogether, both in flower and foliage. This last is wine-coloured, and the blooms are of the colour of ripe mulberries. In purples I like the redder-toned Purple Emperor, but the few visitors who have seen my collection this year all prefer the rich and deeper coloured Purple King. I fancy I ought to say I like Mrs. Humbert, but, somehow, I do not particularly care for it.

I do not love thee, Doctor Fell,
The reason why I cannot tell;
But this alone I know full well,
I do not love thee, Doctor Fell.

It is a pink, but neither so large a flower nor such a pretty shade as we find in Salmon Queen, which is my choice in this colour. Carmineus, a very lovely shade of cerise, makes my sixth in this list, but were they placed in order of merit it would follow B. Ladhams.

Kimbridge, named after the village where Mrs. Humbert lives, is a weird mixture of almost magenta flowers and deep-coloured foliage. I think I would like a big mass of it. The improved form of syphilitica itself is well worth growing, as the pale blue flowers are rather larger and have a much clearer look than the original. Syphilitica alba is all right for those who like white flowers. I ought to add that syphilitica itself and pretty well all its hybrid forms are excellent for those who have bog or waterside gardens to think about. They do well in such positions.

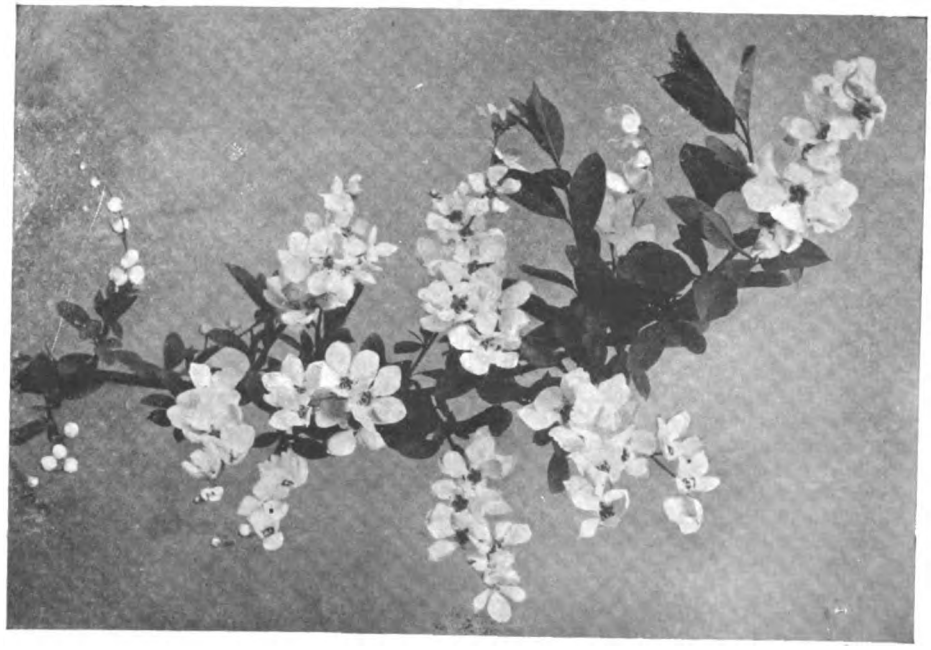
JOSEPH JACOB.

SOME CHINESE SHRUBS & TREES of our GARDENS

(Continued from page 539.)

CORNUS controversa is a species of wide distribution, found in Japan, Korea and western China. Trees which have been planted about fifteen years are now rather over 25ft. high, and flower and fruit profusely. At the season of flowering (late June) the upper sides of the branches are thickly covered with flat flower clusters 6ins. or 7ins. in diameter. The flowers are of a creamy white colour, followed by glossy fruits of a metallic blue, which are, unfortunately, readily devoured by the birds. C. Kousa is native to Japan, and also found by Wilson in central China. It is the exceptionally large white bracts which give the garden value to this species. It may well be considered one of the most ornamental small trees introduced by him from China. There are to be seen in gardens two forms of this species, one inferior to the other. The finest form is that discovered by Wilson in China and the inferior form is of Japanese origin.

The cotoneaster, as before stated, is one of the genera which has had a large number of additions from China. No shrubs are more easily cultivated than these. They thrive in any soil that is not too waterlogged, and are very well adapted for covering chalk banks and similar poor soils. Found most abundantly in the cool temperate regions of northern Asia and especially China. It is not a genus that can boast of showy flowers, although even these cannot be despised by any lover of plants. Their great garden merit lies in their wonderful



EXOCHORDA GRANDIFLORA A DECIDUOUS SHRUB OF GREAT BEAUTY. PRODUCES SNOW-WHITE FLOWERS IN MAY.

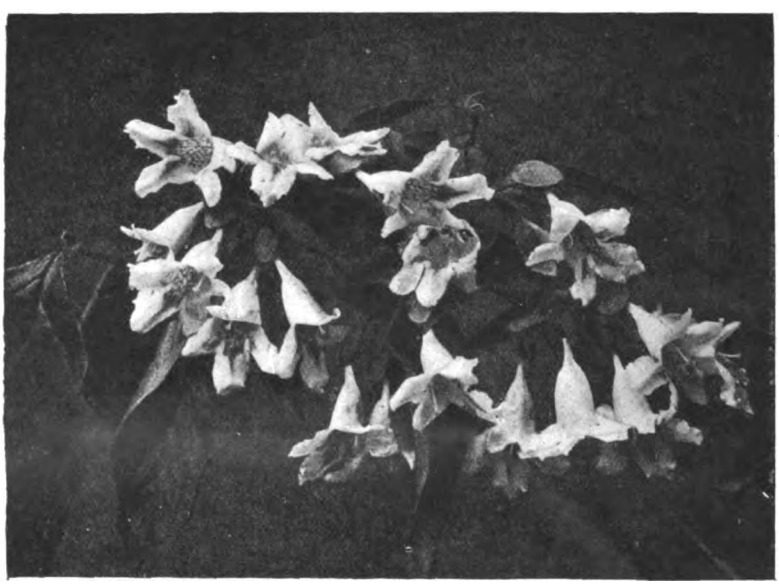
Digitized by Google

berrying propensities. It is a genus comprising species of very widely diverging habits of growth, varying from prostrate subjects suitable for the rock garden to small trees, and from graceful, pendulous, arching shrubs to those of stiff and rigid upright form. The following represent these four habits:

C. adpressa, a very dwarf, close-growing, rigidly branched, deciduous, prostrate shrub, not exceeding about 1ft. to 1½ft. in height; while C. humifusa is of similar habit but evergreen. Both species berry freely in the autumn. One of the best prostrate spreading species for mass planting is C. horizontalis (Davidiana), which is capable of beautifying any unsightly bare spot in the garden. Of the Chinese tree-like cotoneasters, mention must be made of C. pannosa with its masses of small red berries and silvery evergreen foliage, and C. Franchetti with its larger orange red fruits and similar but larger leaves. (The two species which attain the greatest dimensions are the well known C. frigida and the less frequently seen C. Lindleyi. The latter bears black fruits. Both are natives of the Himalaya.) Of the pendulous evergreen species, C. salicifolia and its varieties, C. Harroviana and C. Henryana, are the most worthy of notice. The latter is of a more tabulate than drooping habit. In this class, as in most, the fruits hang in corymbose masses and vary in shades of red. C. rotundifolia is of stiff, angular, branching nature, and possesses fruit of an exceptionally bright coral red. Another of this class is C. bullata, the fruits of which are the largest of any species in cultivation. A counterpart of this species is C. moupinensis, differing in possessing black fruits; this plant is seldom seen correct to name outside a botanical garden.

Enumerated in Sargent's book of Wilson's introductions are twenty-six species and varieties of daphne. Of those native to China, Daphne Genkwa is a real gem, and when laden with its blue flowers is a sight that may well make any garden enthusiast envious of possessing a specimen. It is a deciduous species, the flowers opening in early May before the foliage buds expand. It was introduced from China by Fortune as early as 1843, and later from Japan, where it has long been cultivated but is not a native. It is a plant calling for particular attention, and cannot be classified as a shrub of easy cultivation.

Daphne retusa is an evergreen species. Its flowers are not unlike those of the well known D. indica. It is, however, much hardier than the latter and differs much in its habit of growth, which is stiff, dense and erect. It usually does not attain a height of more than about 2ft.



THE FRAGRANT FLOWERS OF DIPELTA FLORIBUNDA.

Deutzias are a large, beautiful and easily cultivated genus of hardy June-flowering shrubs. All the species bear a great, common resemblance one to another. In habit of growth size, form, and colour of flower and leaves there is a distinct family likeness. The most beautiful representative is D. longifolia var. Veitchii, a deciduous shrub with long, narrowly ovate-lanceolate leaves, and carrying in June corymbose inflorescence 2ins. to 3ins. across of rosy purplish flowers, which in size and richness of tint make it the best Chinese deutzia in cultivation.

Exclusively Chinese are the dipeltas, of which there are only four known species, allied to and very closely resembling the well known diervillas. The most frequently seen is D. floribunda. It is a deciduous shrub attaining a height of about 8ft. to 10ft. The flowers are fragrant and produced either solitary or in small clusters of up to six in each inflorescence, pink, marked with yellow at the throat of the funnel-shaped corolla. The thin bark of the old wood peels off in large flakes, individual pieces measuring 1 ft. or more in length.

Euonymus alatus and its several varieties are found both in China and Japan. Its somewhat corky winged wood makes it one of the most distinct of the genus. Its great garden value lies in its quality of being able to assume very fine autumn colourings. In a recent bulletin of popular information published by the Arnold Arboretum this shrub is spoken of as being without a rival in the brilliance of the deep rose colour passing to scarlet, of its autumn leaves.

Closely allied to the spiræas is the exochorda, a small genus of deciduous white-flowered shrubs. A fine variety is E. grandiflora var. Wilsoni, with extra large paper-white flowers borne on slender, arching stems. It is, as are all members of this genus, of very elegant habit of growth, with slender drooping branchlets.

There being so many Chinese hydrangeas, it is difficult in a short article of this kind to know which to include. Forty-five species and varieties are described in "Plantæ Wilsonianæ." H. Sargentiana with its large rough leaves and bristly thick young growths make it an effective subject for a sheltered border or woodland, and H. strigosa macrophylla, a shrub which is capable of attaining a height of 6ft. to 8ft., when covered with its large bluish flat inflorescences, forms a unique and pleasing sight.

Of hollies, one which is a native of central and western China, Ilex Perneyi, is a valuable and handsome addition to the slow-growing evergreens. Its somewhat squarish, peculiarly formed spined leaves are distinct, and when once known can never be confused with any other species. As with all hollies, its attractiveness is greatly enhanced when in berry.

Both on account of its hardiness and prettiness, Kolkwitzia amabilis deserves a place in every shrubbery; even when not in flower it is conspicuous by the remarkable elegance of its growth. The delicate pink flowers, flushed with yellow, are produced during late spring and early summer; in form and colour they resemble Dipelta floribunda, but in size may best be likened to the flowers of that beautiful villa garden shrub, Abelia longitula.

Included in the numerous privets native to China are both evergreen and deciduous species. One of the prettiest small-leaved evergreens is Ligustrum ionandrum, with its dark, almost blackish green glossy leaves, which do not exceed about one-third of an inch in length. The clusters of black fruit are similar to those of our native privet, a despised plant, although one of the most handsome of black-fruiting bushes.

Chinese honeysuckles are a genus comprising very variable species. Some are of shrubby habit, while others are climbers; some are evergreen and others deciduous.

Lonicera nitida in flower is quite inconspicuous. It is a dense bushy evergreen shrub, with slender, arching branches bearing leaves in form and size not unlike those of the Ligustrum ionandrum. It is very unfortunate that a hardy shrub with berries of so unique a colour should be so unproductive. L. ligustrina, which is almost identical with L. nitida, differing a little in its more upright habit of growth, is here proving itself to be a more free-fruiting species. The fruits of both these species are of a shiny, translucent texture and of a distinct purplish colour. LL. syringantha and thibetica, with their delicate lilac-coloured and scented flowers, are both welcome additions to the shrubby honeysuckles. Of the newer Chinese climbing honeysuckles, L. Henryi is worthy of note. Its large evergreen leaves and clusters of almost jet black fruits in autumn are its two best qualities.

H. G. HILLIER.

(To be concluded.)

THE INTEREST OF THE HARDY CYCLAMEN

PERHAPS no small genus of plants yields a richer harvest of interest to naturalist and horticulturist alike than does the cyclamen. In the first place, to all except botanists it must come as a surprise to find that the cyclamen belongs to the same family as the primrose. The cyclamens are a very select family, comprising but few species, and these come from a very restricted area in southern Europe and western Asia. In our gardens we can only persuade those from southern Europe to grow. The collector's zeal is soon satisfied, and yet each individual has some point of interest peculiar to itself, apart from such characteristics as the reflexed petals and the marvellously twisted bud, which are common to the whole family. There appears to be a good deal of doubt and confusion among the various authorities as to how many distinct species really exist. Robinson, in his " Flower Garden " (twelfth edition, 1914), gives some six.

In their native haunts the cyclamens are found in the shelter and shade of a copse or small wood. If we are to have any success with these little flowers in our gardens, we must try to imitate these conditions when planting the corms. The hardy cyclamens fall naturally into two groups, those that flower in the spring and those that produce their blooms in the autumn. The best known of the spring-flowering cyclamens is C. Coum, which has dark green foliage and rose-coloured flowers. This comes into flower very early—often, in fact, before the snowdrop. On this account it is a most valuable asset to the winter garden.

Whether C. ibericum is a distinct species or merely a variety of C. Coum seems to be a moot point. It is a very variable plant with foliage more or less silver-zoned and flowers of various shades from white to deep crimson. Then there is C. vernum which comes into bloom about April or May. The silver-marbled leaves of this species appear first before the flowers.

Of the autumn-flowering cyclamens we need make mention of but two, C. europæum and C. neapolitanum.

The first of these is very common in Switzerland and is there known as " Alpen veilchen," Alpine violets, by the school children, who pick bunches of them as do our own children their cousins, the primroses. These fragrant bunches of little crimson flowers they offer to tourists for a few centimes. The flowers looked very pretty growing in thousands in a little copse on the shores of the Lake of Lucerne, where the writer saw them some years ago.

CYCLAMEN COUM, WITH ROSE-COLOURED FLOWERS.

In September or early in October C. neapolitanum pushes up its buds from the bare soil before the leaves have appeared. When the stems have reached some three or four inches the charming little pink flowers open. There is also a lovely white variety which is not so common. When the flower fades and the seed is set, it drops off. Nature then performs one of her miracles. The stem proceeds to coil itself up. Day by day another coil is added to the spiral until the seed capsule is brought close to the ground and, in fact, is often forced into the soil. This, as Reginald Malby suggests in " The Story of My Rock Garden," is a provision of nature to ensure the next generation, as, flowering late, the seeds would be exposed to all the inclement weather. The leaves of this choice plant expand after the flowers and are very beautifully mottled with silver. They remain fresh the whole winter through and on into the early spring. They thus form an admirable setting for such early-flowering bulbs as the snowdrops, scillas, chionodoxas and the miniature daffodils, serving also as a protection against the soil splashing on the delicate flowers. E. CAHEN.

NOTES OF THE WEEK

NOTES FROM A GLASGOW ROCK GARDEN.

WITH shortening days there is a noticeable falling off of flowering plants, and perhaps this lack of flowering commences sooner and is more pronounced on the rockery than in any other part of the garden.

There it is that many plants, which, even though they may bloom in the hey-day of the season, are not given a second thought then, because they are eclipsed by the glory of plants which are essentially alpines.

Plants, therefore, which remain in bloom or produce blooms from August onwards are, indeed, valuable. Whether or not plants will bloom so late depends chiefly on the times of planting and the atmospheric conditions, and those which do flower then seem to be worthy of more than passing notice.

From among others the following have been noted as blooming well late in the season :

Arenaria montana is a sticker of the first water, for after commencing to flower early in June, it is still going strong.

Campanula arvatica (received here as C. acutangula) has been for a long period, and is yet, sending out its sprays of star-like, almost purple flowers. Plants of this, put on a deep ledge of a newly constructed piece of rockery having a western aspect, have been remarkably prolific. Plants of C. haylodgensis are still yielding many of their pale blue, bell-shaped flowers. Of the white campanulas now in flower (early September), the two most prominent are C. carpatica var. alba, carrying its fairly large saucer-shaped flowers on a spray, and C. Warley alba, a splendid semi-double, which it may be noted, recently received an award of merit. Of procumbent habit, it flourished in a loamy, gritty soil in a pocket near the path and a thin top-dressing of granite chippings proved of immense value in preventing the petals becoming splashed with dirt during the showery weather.

It was not until the last day of August that Dianthus graniticus gave up flowering. With us is has been one of the most free-flowering of its genus and with its low growth and its erect stems which attain a height of 4ins. to 6ins., and usually carry two red blooms, it certainly is a desirable plant.

The most conspicuous member of the heronbill family just now is Erodium hymenodes, but, alas, I fear it will be the first to object to an early frost. Gentiana Freyniana is, with us, the sole one now in flower, and how gorgeous it is. Its colour would ensure admiration at any season, but now,

Digitized by Google

in the late season, it seems particularly attractive.

New plants of Mazus Pumilo, native of New Zealand, have given the greatest satisfaction in a shaded nook. With August came the meadow saffrons, the two first being Colchicum autumnale and C. speciosum. Plants of Myosotis azoricus raised from seed sown in the spring are now producing compact heads of flowers of a rich violet colour. True to its reputation as a late flowerer, the winter savory, Satureia montana, commenced showing its whitish-purple blooms about the middle of August and now the plants are a mass of bloom. Of the stonecrop, Sedum Ellacombianum is decidedly the most noticeable here just now. Scutillaria indica var. japonica is persistent with its supply of purplish flowers, and the yellow-flowered S. orientalis is a good late season plant.

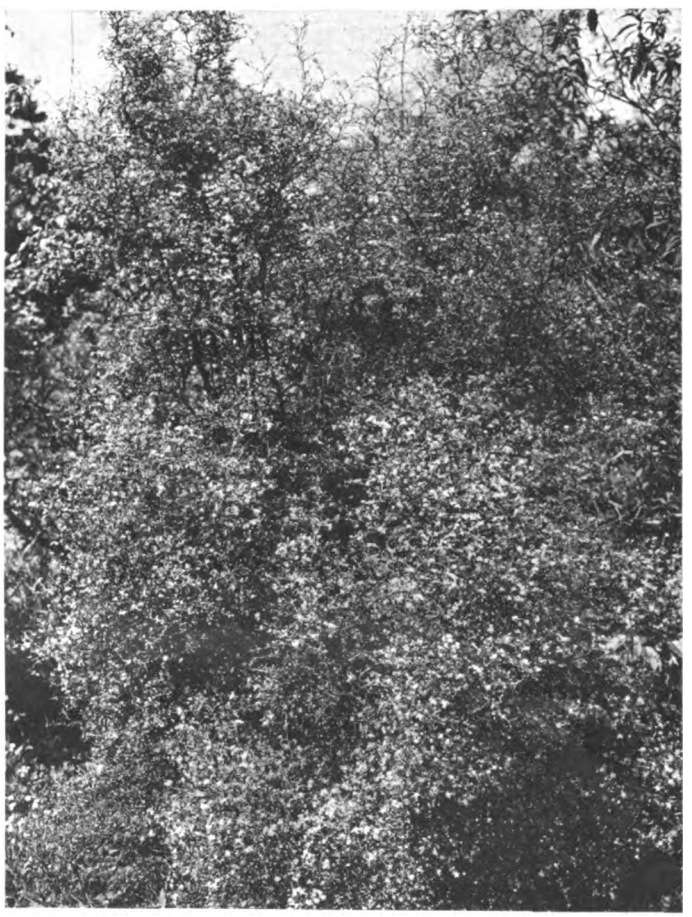
To close these notes without mentioning Viola orphanidis would, to my mind, be wrong, for this gem, straggly though its growth, can be relied upon to go on sending out its miniature pansy blooms long after other plants have retired for the season.

True it is that some of the later-flowering rock plants are not of the high quality of some of the early season plants, but it must be remembered that blooms now are particularly welcome and the plants which will supply them should be considered when preparations for next season's flowers begin.—W. HOWELL.

COROKIA COTONEASTER.

THIS curious member of cornaceæ is so often quoted in articles, and such fine specimens exist at such gardens as Nymans, that it is a wonder it is not more commonly grown. It is a native of New Zealand, where it lives in the scrub in dry districts up to 3,000ft. The native name is Korokio. It is an evergreen shrub up to 8ft. in height and, as will be seen from the accompanying illustration, the branches are peculiarly twisted and interlacing. The leaves are smallish and obovate, covered below with a thin white tomentum. The flowers are numerous, star-shaped, about ½in. in diameter and of a good clear buttercup yellow. It does not often fruit in this country, but the fruit is in the form of red drupes, like small Cornelian cherries. In the south and west it has long been sparsely grown in the open and has succeeded extremely well. In the north and east it is usually grown as a wall plant, but there is every reason to suppose that in many gardens it will thrive in the open if sheltered from the east and north.

In New Zealand both C. Cotoneaster and the other two species, C. buddleioides, with large dark green shining leaves about 3ins. to 5ins. long, and C. macrocarpa, from the Chatham Isles, with broader leaves, are rapidly becoming more popular in gardens, which is a proof of their worth, for New Zealanders are stern critics of their own native plants. There is also a hybrid in existence, C. Cheesemanii, a cross between C. Cotoneaster and C. buddleioides. It is doubtful if C. buddleioides would grow in this country, except in the west, as it comes from the neighbourhood of Auckland in the extreme north, but C. Cotoneaster is such an interesting plant that it is well worth growing in a position where it can be sheltered from cold winds and yet get the maximum of sun.



AN OLD BUSH OF COROKIA COTONEASTER AT NYMANS.

HARDINESS OF RHODODENDRONS IN DENMARK.

[The following interesting note has been received from a Danish correspondent. Excepting RR. auriculatum, decorum and Williamsianum, which stand in half shade, they are all growing together on a slope facing east, in full sunshine from sunrise to three or four in the afternoon.—ED.]

THE undermentioned rhododendrons have withstood two severe winters without damage, unless otherwise stated. The numbers nineteen and ten after the names mean degrees in Centigrade below the freezing point during the winter 1923-24, an exceptionally long and severe winter here, and ten degrees in March 1924-25. Many buds had started to open in the mild weather in February, followed by many nights with temperatures ten degrees Centigrade under the freezing point.

Where stated "Börgesen," the observations are reported by Dr. Phil. F. Börgesen, Hellebæk, in Denmark, who also made some observations in the hard winter of 1921-22. Otherwise the observations are made by me in my garden at "Brændkjærhöj," Kolding, Denmark, on a very exposed place and rather windswept.

Aemulorum, 10; ambiguum, 19; argyrophyllum, 19; auriculatum, 10; brachyanthum, 10; brachycarpum, 10; calostrotum, 10; campylocarpum, 10 (Börgesen); canadense, 19; Catawbiense with hybrids, 19; caucasicum, 19; chamæcistus, 10; cinnabarinum, 19 (Börgesen); concinnum Coomb., 19 (Börgesen); concinnum Harrow, 19; dauricum, 19; Davidsonianum, 10; decorum, 10; fastigiatum, 10; ferrugineum 19; flavum and many of its hybrids, 19; Fortunei, 19; glaucum, 10 (with a little glass protection); hippophæoides, 10; hirsutum, 19; hybridum, many hybrids, among them Cunn. White, 19; Loder's White, 10; Pink Pearl, 19; præcox, 19; impeditum 19 (Börgesen); intricatum, 19; kamtschaticum, 19; Kæmpferi, 19, rather badly damaged, but not killed; ledifolium, 19; lutescens, 10; maximum, 19; pentamerum, 19; molle with hybrids, 19; moupinense, 10; mucronulatum, 19; multiflorum, 10; nudiflorum, 19 (Börgesen); occidentalis, 19; obtusum amœnum and Hinodigiri, 10, badly cut back, but not killed; oleifolium, 10, as obtusum; oresbium, 10 (Börgesen); oreodoxa, 10; oreotrephes, 10; parvifolium, 19; plebeium 10; ponticum, 19, some badly damaged, some undamaged (Börgesen); pseudoyanthinum, 10; punctatum, 10; racemosum, 19, badly cut back, but made good new growth; rubiginosum, 10; Smirnowi, 19; Thomsoni, 10; Vaseyi, 19; villosum, 10; viscosum, 19; Williamsianum, 19; yanthinum, 10; yunnanense, 10, flower buds damaged, probably because they were near to open in March when the frosts came. —AKSEL OLSEN.

NOTES ON CHRYSANTHEMUMS.

THE border chrysanthemums are charming plants and enjoy the favour of rich and poor alike. Their popularity is so wide that they are to be found growing in the gardens of the great and in those of the humble cottagers. This, of course, is not to be wondered at when we think of the floral fête of fairest flowers flaunting their richest tones of gold and brown and other shades, making the gardens gay with colour over a lengthy period, right on, indeed, until the days get dark and dismal and approaching winter draws quite near.

Many and varied are the varieties in cultivation. Yet Mme. Marie Masse and its many sports have had a firm foothold in gardens for many years, and are still very popular. We cannot, of course, marvel why the chrysanthemum has gained such widespread favour, when we see such finely coloured and well formed flowers so freely produced by each plant, and I venture to say that poor, indeed, would be an autumn display in a garden without the charming "mums."

Then, as cut flowers and decorative material they have secured a very high place in the floral world. The ease, too, with which plants can be grown and propagated has, no doubt, added greatly to their universality.

However, we must not think that plants will grow well anywhere, as starved and neglected chrysanthemums present a sorry spectacle, and, usually, it is those neglected plants which harbour and have their foliage disfigured by that troublesome and dreaded pest, the leaf miner, which is the maggot of the marguerite fly.

Varieties there are which show shyness in producing young growths in quantity at a period of the year when cuttings are wanted. Chrysanthemums of this category should be lifted before winter sets in and placed in a cold frame or in cutting boxes among a light sandy compost.—D. A.

APPLE ST. EVERARD.

DIANELLAS.

THESE beautiful and easily grown plants are, unfortunately, all too rare in our gardens, and the ease with which they are propagated makes this all the more difficult to understand.

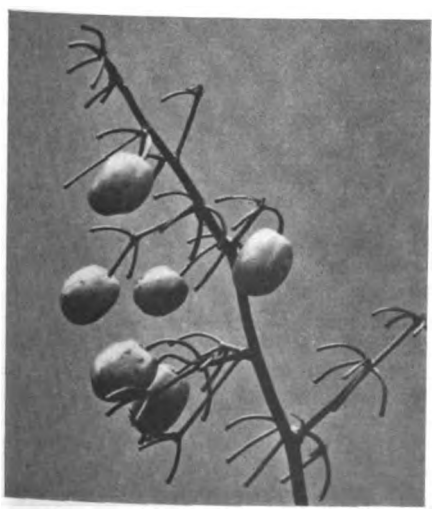
There are some half-dozen varieties in cultivation in this country. They are considered tender, but I have grown them in exposed positions in both Surrey and Sussex without injury of any kind, and, moreover, the plants grew well and increased rapidly.

They are natives of Australia and Tasmania, and their chief beauty lies in the wonderful blue berries, produced in some cases by the hundred.

Just fancy: berries of the richest blue and the size of hazel nuts, hanging in clusters on their thread-like stems. The nearest approach to their loveliness being the fruit of Billardiera scandens, also from Australia. The foliage is of varying length in the different varieties, and ranges in length from a foot or so up to 4ft. In colour it varies from glaucous to deep green, and in all varieties it is grass or sedge like.

Propagation is effected by division and by seeds sown in spring in gentle heat. A position in the herbaceous border or front of shrubbery is suitable for them. They do well in a good loamy soil to which is added a little peat or leaf-mould.

The varieties mostly met with are: D. cœrulea, which bears fruit of large size, of brilliant blue, and stout foliage; D. intermedia, a slender grower, producing graceful sprays of dark blue fruit the size of large black currants; and D. tasmanica and its variegated form which reaches 4ft. when well grown, and presents a beautiful picture.—J. HILL, *Paignton*.



THE BLUE BERRIES OF DIANELLA TASMANICA.

TWO GOOD APPLES.

IN St. Everard we have a first-class dessert apple, and it is undoubtedly the finest flavoured early apple in commerce. It was raised from Cox's Orange Pippin and Margil, and it is in season in September. The colour is a ruddy crimson, and the flesh rosy yellow, being very crisp, sweet, juicy and of a fine aromatic flavour. In general appearance and size it is somewhat similar to Cox's Orange Pippin, and it is valuable on account of the fact that it ripens much earlier than that well known apple. The tree is a good grower, and a prolific bearer.

There has been a great demand for this apple during the last two or three years, and late in the season of 1924–25 it was difficult to procure good specimens. Therefore, it behoves readers who wish to secure this excellent and desirable variety to place their orders in the near future.

Rev. W. Wilks is another apple admirably suited for both small and large gardens, in fact it is everybody's apple, because it will bear a good crop of fruit on very small trees. It is a culinary variety, excellent for kitchen purposes during the month of September, October and November. The specimen illustrated was supplied by Mr. J. C. Allgrove, Langley Nurseries, Bucks, where this splendid apple was raised from Peasgood's Nonsuch and Ribston Pippin. It weighed exactly 16 oz., was 12ins. in circumference and 7ins. from eye to stalk. The flesh is white, juicy, and pleasantly flavoured, while the skin is yellowish green, spotted with brown and scarlet. The variety possesses a robust constitution, and produces plenty of stout fruit spurs. When cooked it is delicious, and for baking purposes it is among the best. On the show bench it generally heads the list in its class.—T. W. B.

WHITE HEATHERS.

THERE is a popular opinion that all heathers are difficult to grow and that the "White Heather" of romance is never really seen in gardens. Both of these ideas are, of course, entirely erroneous. Heathers will flourish in any lime-free loam and generally do as well, if not better, under cultivation, than on the moors. This last remark applies to "White Heather" in particular, there being a number of varieties of Calluna vulgaris in white which, while they vary very widely in length of flower spike and stature, can all claim to be, if not the genuine article, something much nearer to it than the "Scotch White Heather" one sometimes sees being offered as bait to the unwary.

As the best time for planting is at hand, I would like to draw attention to the singular merits of the finest of all the early-flowering white heaths, Erica mediterranea alba. This is rather more dwarf than the type, an extremely generous producer of long spikes densely furnished with blossoms in a good, clean white, and it is hardy enough for practically anywhere. This beautiful variety is especially valuable inasmuch as it flowers from the end of March to late spring and it is surprising that it has not been more widely taken up as a commercial proposition by those who make it their business to supply cut flowers for various purposes.

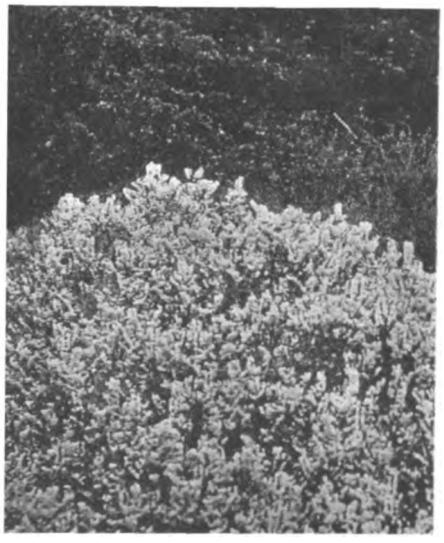
Passing over the tree heaths, the next good white to appear among the dwarfs is E. cinerea alba. This, however, is not always as satisfactory as it might be, despite the darker green of the foliage, which helps to accentuate the pure white bells. We have yet to greet the appearance of a white cinerea which is as large in the flower raceme as a good form of rosea. Even so, this white bell heather is by no means to be despised and it has no rivals during its own season, if we except the varieties pallida and Apple Blossom. These, if not actually pure white, are near that colour in effect and both are excellent.

APPLE REV. W. WILKS.

There are several white forms of E. Tetralix, but none of these is particularly striking. E. t. mollis, with its downy, grey-green foliage, is distinct, the præcox alba is generally earlier than the ordinary white form of the type. This last varies very considerably and a day's search on almost any summer moor where the species abounds will reveal a useful selection. E. Tetralix, as a garden plant, fails in comparison with its allies on account of the fact that its flowers are borne only in terminal heads rather than racemes, but the plant is nevertheless one of remarkable charm.

E. ciliaris alba hardly lives up to the reputation of the fine species to which it belongs, and as for E. vagans, I never considered any of its so-called white forms worth growing until I came across var. Lyonesse, which is a distinct acquisition. Some years ago one got news of a white variety of E. australis, which ought to be a lovely thing, but whether it is in existence I do not know.

So to where I began, to the "White Heather" of Scotland—and many other places if the north will allow. Calluna vulgaris is richer in white forms than any of the preceding and the planter may select from the lists a number of varieties from little shrubs of a few inches high to vars. Hammondii



A BANK OF ERICA MEDITERRANEA ALBA.

Digitized by Google

and Serlei, which will make bushes 3ft. and more in height. For general garden use Serlei is, I think, the best, its foliage being "feathered," and of a fresh green, while the enormous heads of pure white blossoms are very handsome. A variety known as alba gracilis is exceedingly pretty and usually under a foot high; alba rigida is another of the smaller kinds with stiff, upright spikes; alba pilosa is a form with a greyish foliage and then we have the common white variety (C. v. var. alba) of the moors, with its pale green foliage and prettily tapered spikes of white. There are many others included in some lists, but most of these are too much alike to claim distinction as garden subjects. Moreover, heaths, like not a few other subjects, are apt to vary very considerably in accordance with the nature of the soil and the treatment they receive under cultivation.—A. T. JOHNSON.

EARLY VEGETABLES

BY EDWIN BECKETT.

IF one delves into a modern reference book that gives details of the various imports made by Great Britain, one cannot help being struck by the enormous figures that represent payment for imported vegetables. While one appreciates the fact that certain other countries have, possibly, more genial climates than our own, and earlier sun power than we are blessed with, yet we cannot overlook the fact that when considering the position of early vegetables on our markets there is a great deal more that could be done in this country. Some have the facilities for attaining this, many have not, but a far greater measure of early supplies could well be attained with little extra trouble and expense.

These notes are not intended to be exhaustive of the subject, but to point lines of action to those who have not fully considered the means and ways, but who would like to take up the good work to their own pleasure and profit.

THE APPARATUS.

Of course the whole work depends on the utilisation of heat: either that of such heat as may be directly obtained from the rays of the sun, in that simplest of apparatus, the cold frame; the stored heat of the sun, such as is yielded from the fermenting material of hot beds and caught by frames placed thereon; or by the employment of again stored sun heat in the form of fuel, when used for heated pits or glasshouses.

THE SUBJECTS.

In one way or another practically all vegetables could thus be brought in season at earlier dates than we have them in the general run of things, some, of course, far more successfully than others, but it is not a necessity in all cases. Who would really want, say, an ordinary cabbage brought along under glass for the pleasure of utilising it a week or two earlier than those grown in the open, therefore we will only consider some of the more important items for this treatment, and from two points of view (*a*) those grown under glass for early use, and (*b*) those raised under glass for planting out with a view to advancing the date at which they may be employed by the culinary department.

Dealing with the latter, and smaller, group first, one finds a few items, such as onions, celery, brussels sprouts, etc., that may be brought along for early supplies in the open by the aid of glass. These are of less consequence for these notes than the other group, though it must be noted that there is a distinct advantage in thus treating the onion crop, for by sowing in gentle heat in January, pricking out when sufficient size, with a view to planting out at an early date, not only are larger specimens obtained, but early maturity and ripening are attained. While the ravages also of the onion fly are practically escaped. Celery sown in moist heat in February will give early plants that can be grown on the flat, and blanched by means of brown paper collars, for early supplies, and can also be obtained at even earlier periods, if planted in pots and frames.

Of the other section we must divide into three classes: the first, those for which a mushroom house or cellar is required; the second, those for which frames, pits and houses are employed; and the third a small group whose season is really prolonged by the use of these structures, in addition to early supplies, through utilising the frames, etc., to protect from frost.

The cellar section comprises, principally, mushrooms, the making of fresh beds monthly for which enables the production of these to be attained all the year round. Chicory, which, commencing in October, may be brought along in successional supplies for salading, all through the winter in the mushroom house or moist cellar. Seakale, which, commencing in pots in the mushroom house or cellar in November, may be obtained through the winter until the supplies from the plants in the open may be arranged for. Rhubarb, which may be started in October from selected crowns, planted in a little soil in the same structures.

The third group of prolonged season vegetables, includes such items as lettuce and endive from August sowings made for winter supplies. These are pricked out into cold frames for the purpose in September, while in October older plants growing in the open are lifted and packed close together in cold frames for winter protection, the blanching of the endive being accomplished by covering sufficient from time to time with a mat to exclude the light. Parsley may also be obtained for winter use by sowing in cold frames, and pricking out when through, at sufficient growing space, while as a catch crop, radishes may be sown from time to time, as required, between the rows of other vegetables growing in frames and pits, such as potatoes, carrots, cauliflowers, beetroots, turnips, etc. Mustard and cress should also be raised throughout the winter, for salading, by frequent sowings in boxes, and raised in the glasshouses.

IMPORTANT VEGETABLES.

The middle and most important group, comprises cauliflowers sown about the second week of September, pricked out in cold frames in October for wintering, ready for early planting in the open. Some of the strongest of these plants may be grown on in cold frames to give earlier yield than their fellows, while for earlier supplies still, plants of suitable forcing varieties raised from seed sown in gentle heat during December and January can be grown well in pots, finishing their growing stage in a cool vinery. Tomatoes for early spring work sown in gentle heat during September, and for winter supplies in August. Carrots which can be sown in a heated brick pit with sufficient depth of good compost during the first week in January, while stump-rooted varieties can be sown at the same time in frames on a hot bed. French beans which may be sown in 8in. pots in November, and raised in a temperature of not more than 65°, while successional sowings can be made until it is time to sow in the open. Asparagus, which can be forced splendidly in frames on a hot bed, strong crowns being selected for the work, and a start made in December. Broad beans, which can be grown in large pots or boxes in a cool vinery, and can also be raised in boxes in cold frames for April planting in the open. Peas are excellent for growing in pots from January sowings in cool houses, and may also be box-raised in February for growing on in these receptacles in the open later on, and finally should be raised in boxes under glass from March sowings for transplanting in the open for early supplies therefrom. Potatoes also force excellently in heated pits, cold frames, and even in large pots or boxes in a cool house. The sets for the latter are planted in December, for the pits in January, and for the cold frames in February, and if sufficient room in such frames, again in March to continue the supplies till those in the open come into use. Turnip sown in cold frames about the middle of February will yield nice early supplies; while globe beet may be similarly raised in frames on a mild hot bed, sowing in March. Mint and tarragon also lend themselves to forcing well in boxes in frames on a mild hot bed, a start being made with this about the end of February. Vegetable marrows sown in heat in February, may either be grown in large pots or planted in frames on a mild hot bed with great success. The lights and frames should be removed entirely when safe from frost, as growth progresses.

(To be continued.)

THE HOLLAND PARK SHOW

THE Holland Park Show, as usual, has been an unqualified success. Considering the terrible weather of the few days before the Show, all exhibitors deserve great credit, particularly those whose exhibition blooms were grown in the open air. It is, indeed, surprising how few exhibits showed the least sign of being damaged by the gales and rain of the previous few days.

A PORTION OF MESSRS. CARTERS' EXHIBIT.

STOVE & GREENHOUSE PLANTS.

The only exhibit from a private garden was the wonderful group of tropical crotons from Mr. A. P. Brandt of Bletchingly, and this was one of the best in the Show. Time was when these handsome foliage plants were grown in most gardens, but now they are comparatively rare, though the decorative value of the highly coloured foliage is very great. A large number of distinct varieties was represented and each was perfectly grown.

A particularly attractive group was arranged by Messrs. Carter and Co. The centre was made up of a large square containing many lovely plants of Lilium speciosum Melpomene, bordered with the blue-flowered Browallia speciosa major and surrounded by rich green grass. Around this charming centre was disposed smaller circular groups of magnificent plants of Clerodendron fallax, bearing large heads of vivid orange-scarlet flowers, and cut spikes of very good gladioli.

In a prominent position near the centre of the hall, Messrs. Sutton and Sons had a striking ground group of gloxinias, which was particularly interesting owing to the culture of the plants exhibited. These gloxinias were sown as late as last April, and have been grown in cool greenhouses with little artificial heat. Some of the best varieties shown were King George V, Firefly, Duchess of York and Pink Beauty.

Messrs. John Peed and Son are famed for their caladiums, gloxinias and streptocarpus and their exhibit of these glasshouse plants at Holland Park Hall was fully equal to their collections in the past. The caladiums had huge leaves of such delicate transparency that it seemed impossible that such could grow and remain so for months. Rio de Janiero is a typical variety of this type, while General Hamilton combines vivid crimson colour with delicacy of texture, and Marie Moir and Mrs. Robson have fascinating variations of pale green and transparent white on large leaves. An enormous quantity of gloxinias of a splendid strain were shown, but, good as they were, they were surpassed by the streptocarpus. Zonal pelargoniums, which, like the tropical crotons, once were considered indispensable for the summer decoration of the glasshouse, had only one exhibitor, but Mr. R. J. Case brought many trusses of flowers of rich, glowing colours. A selection of his single-flowered varieties would include A. J. Macself, purple; Exquisite, rosy pink; His Majesty, immense scarlet; Lady Warwick, white edged with pink; Somerset Lad, soft salmon; and Mrs. W. A. Cull, white. The double flowered varieties were also well shown.

An imposing collection of tuberous-rooted begonias was staged by Messrs. Blackmore and Langdon. These were all of their well known type which make sturdy plants carrying perfectly double flowers, often larger than a large camellia and of delightfully varied colours. Of the very many sorts time and space permitted the noting of only a few. F. C. Calthorpe seemed to be the best scarlet. Queen of the Belgians and Mrs. H. A. Fox are excellent pinks. Mrs. J. Davidson is rich yellow, while Pavlova is of deep orange. Albatross is pure white and Mrs. F. Cairns is a charming picotee on white ground. Mabel Langdon, a fine soft rose, shows the first appearance of a new break where the flower is cupped like a rose with no appearance of any reflex in the petals.

A GROUP OF GLOXINIAS. AS SHOWN BY MESSRS. SUTTON.

ROSES.

The fact that the Autumn Rose Show was held as recently as last week, did not prevent a number of rose growers from staging large collections of roses of all kinds. Messrs. S. McGredy arranged a collection of good quality blooms to the very best advantage. Many well known varieties such as Betty Uprichard, Golden Emblem, General McArthur, Gwyneth Jones, Lord Charlemont, Doris Trayler, and a beautiful basket of Emma Wright were on this stand. Mr. George Prince had lovely blooms of Los Angeles, Mrs. Henry Morse, Climbing Lady Hillingdon, Sunstar and fruiting sprays of Rosa Moyesii and R. Septipodi.

Roses in perfect condition were exhibited by Messrs. Chaplin Bros., Limited. Beautiful blooms of Emma Wright, pure orange; Mrs. Henry Morse, bright rose; Mrs. Henry Bowles, rosy pink shaded with salmon orange; and K. of K., the popular semi-double scarlet bedding rose, were all well displayed.

Mr. J. Pemberton showed, among his general collection, some new pedigree seedling roses of his own raising. I. Zingari, Pax, Anne, Vanity and The Adjutant, were a few of the best. Betty Uprichard was undoubtedly the most popular rose of the Show. Messrs. D. Prior and Son had beautiful specimens of this variety. Else Poulsen (a new polyantha variety, with frilled salmon-pink petals), Los Angeles, Lady Inchiquin and Golden Emblem, were also noted.

The most outstanding rose shown by Messrs. Alex. Dickson and Sons was Shot Silk, a sweetly scented "Hawlmark" novelty. The colouring was most artistic and the growth free and vigorous. The velvety blooms of Mrs. Oswald Fitzgerald, and the coppery Lady Pirrie, looked very fresh. Mr. Elisha Hicks had hundreds of blooms arranged in pillars. W. F. Dreer, Charles E. Shea, Hoosier Beauty, Lucile Barker and Clovelly

Digitized by Google

were some of his best. Messrs. A. and J. Allen showed, among others, Independence Day, Hortulunus Budde, and the fragrant Etoile de Hollande. Delightful blooms of Flame of Fire, a deep orange hybrid tea, were exhibited by Messrs. B. R. Cant and Sons. Henrietta, Dorothy Page Roberts, Isobel and Hoosier Beauty, were also noted.

The roses on the stand of Mr. Frank Cant received much attention. Lovely blooms of Padre, Golden Emblem, Golden Ophelia and Emma Wright, were shown by this grower. Etoile de Hollande was the most fragrant of all the roses shown by Mr. T. P. Edwards. Lady Inchiquin, Mme. Butterfly and Betty Uprichard, were also delightful. Messrs. J. Waterer, Sons and Crisp had a representative collection of some of the best new hybrid teas. Good shaped blooms of Donald McDonald, Isobel and Old Gold, were to be seen.

Mr. T. Robinson showed a collection of roses, including such sorts as Lady Inchiquin, Sovereign, Henrietta and Miss C. E. van Rossem, a well formed and sweetly scented hybrid tea. Mr. J. Mattock displayed some well grown roses and among them were the varieties Mrs. Redford, Captain R. Clark, Rev. Page Roberts, and a pretty bunch of Lulu, with its small pointed buds of salmon pink. Some splendid roses were shown by Messrs. A. Warner and Sons, and Messrs. S. Bide and Sons exhibited their new perpetual-flowering climbing polyantha called Phyllis Bide.

MABEL LANGDON, A NEW BREAK IN BEGONIAS. SHOWN BY MESSRS. BLACKMORE AND LANGDON.

BORDER PLANTS.

Although a great many firms showed Michaelmas daisies freely, they were usually associated with other hardy flowers. Mr. W. Wells, jun., also had excellent vases of kniphofias, rudbeckias, herbaceous phlox and Scabiosa caucasica varieties. These all showed the excellent quality that is always noticeable in Mr. Wells' exhibits. The last named flower was also splendidly shown by Messrs. Isaac House and Sons, who had a delightful variety and at one end of the tabling grouped vivid spikes of Kniphofia Mount Etna.

Adjoining their excellent clematis Messrs. G. Jackman and Sons had a large collection of general border flowers, including sunflowers, liliums, herbaceous phloxes and pyrethrums. In a large floor group Messrs. Bakers, Limited, associated Scabiosa caucasica varieties, rudbeckias, Sidalcea Rosy Gem, Geum Orangeman, of rich colour, and many other flowers with their Michaelmas daisies. Mr. T. Carlile also had a big group of mixed flowers. His late spikes of delphiniums were particularly good, as also were his gaillardias and lupins.

Mr. Amos Perry had the only collection of hardy ferns and this included many fascinating variations in the forms of their fronds. His very large group of border flowers contained attractive mounds of Lilium Henryi, L. longiflorum giganteum, Kniphofia Golden Spur, K. nobilis and K. Corallina, which pleasantly broke the level of the many herbaceous perennials.

Liliums formed a graceful feature of the pleasant group arranged by Messrs. Wm. Cutbush and Sons, who had especially good stems of L. tigrinum and L. speciosum album rising above their large decorative dahlias, pentstemons, rudbeckias and dwarf heathers. On the staging of the Central Gardens Supplies Co. was a fascinating collection of prostrate plants, such as Mentha Requieni and Raoulia australis, which are suitable for planting among crazy paving stones or on the rugged boulders of the rock garden. They also had a good collection of border plants.

The tall rich yellow Rudbeckia Herbstonne was prominently shown by The Chalk Hill Nursery Co. among their Michaelmas daisies, while along the front they showed the interesting Astrantia major, cut sprays of Polygonum campanulatum and other hardy flowers. A goodly collection of general border flowers was contributed by Messrs. J. Cheal and Sons, who used lupins, delphiniums, rudbeckias, Heliopsis gratissima, Senecio Clivorum and other plants very effectively. A good variety of gaillardias, Aconitum Fischeri, herbaceous phlox and kniphofias were staged by Messrs. G. Gibson and Co.

Coreopsis tinctoria, as shown by Messrs. B. Ladhams, Limited, is a valuable rich yellow border plant and they claim that, unlike C. grandiflora, it is a true perennial. The tall lobelias, in great variety, a splendid plant of Cimicifuga simplex, Poterium obtusatum, and some of the dwarf polygonums, were also included.

A splendid collection of herbaceous phlox was shown by Messrs. John Forbes, Limited, who also had pentstemons in admirable variety. Phlox, shown by Messrs. E. F. Fairbairn and Sons, included Sir Douglas Haig, deep orange; Sir D. Beatty, Monarch and Triumph, varying shades of purple. In front of his dahlias Mr. H. Hemsley had a long row of pot plants of various sedums, sempervivums, gasterias and other succulent plants. A pretty little rock garden and pool was made by Miss K. Hopkinson, who planted it effectively. Sidalcea Rosy Gem, colchicums and solidagos were exhibited by Mr. G. A. Miller, while Messrs. Rich and Co. had a neat collection of perennial sunflowers, herbaceous phlox and other flowers, and Messrs. Reamsbotton and Co. had their customary flowers of St. Brigid anemones.

A splendid strain of marigolds, named Ball's variety, arranged with Aster King George and Nepeta heterophyllus, was contributed by Mr. H. Marcham.

Exceptionally good spikes of herbaceous lupins were displayed by Messrs. A. Harkness and Sons. These were mostly distinct named varieties: Flaming Torch, orange fawn, and Mr. Morris, creamy fawn, being especially charming. They also staged Harvester, September Yellow and Ethel among some early-flowering chrysanthemums.

Violets were exhibited by Mr. Baldwin Pinney and Mr. J. J. Kettle.

The Maytham Gardens exhibited border plants. A splendid strain of antirrhinums was shown by Messrs. W. H. Simpson and Sons. Messrs. M. Prichard and Sons showed fine spikes of kniphofias, together with Lilium auratum and Anemone japonica.

MICHAELMAS DAISIES.

From a study of the list of exhibitors no one could have formed any idea of the numbers of asters, or Michaelmas daisies, to be found in the Show. They were to be seen not only in solid masses, as in the displays of Messrs. H. J. Jones, Ernest Ballard, Amos Perry, W. Wells, jun., and T. Bones, but in more or less isolated specimens in almost every other group where anything in the shape of herbaceous or hardy plants was put up. And yet the date of the Show this year was distinctly on the early side for Michaelmas daisies of the Angliæ and Belgii sections. One of our big growers, Mr. H. J. Jones, could only bring fifteen varieties out of the hundred and fifty that he grows at Lewisham. Many of Mr. Ernest Ballard's were not fully out. And one imagines this lateness of the flowers was the reason why we did not see Messrs. Dickson and Robinson's usual group — London, Malvern and Manchester. There you have it.

If, however, it was early for the tall varieties, not so with regard to the lower-growing Amellus section. Slowly but surely they are gaining favour with the gardening public, and since they come into flower, as a rule, before the others, the Show date suited them, and there was a fine muster. Mr. G. G. Whitelegg had two conspicuous masses of King George, which is one of the best. Mr. Wells had the lovely rose Wells' Favourite. Mr. T. Bones, Mr. T. Carlisle and others had that rich dark gem of a flower, Ultramarine. Messrs. William Cutbush and Son had the deep lavender Queen Mary. Mr. G. Reuthe had the pretty narrow-petalled Stella. Messrs. Wilson and Agar had the dark Onward, and so on.

In the taller sections Barr's Pink, an Angliæ, was well shown by Mr. Bones, but if the truth be told there were very few of the Angliæs in the whole hall. In the Belgii section, as usual, Mr. Amos Perry had a good collection; so, too, had Mr. F. G. Wood and the Maytham Gardens, besides those already mentioned. Graceful spikes of Ethel Ballard, Nancy Ballard, and Rachael Ballard, as well as many old and new varieties in all shades were exhibited by the last named. There were very few novelties. Mr. H. J. Jones had a white, named after himself, H. J. Jones. It is expected to have a great future. "It's always there." Mr. Ballard had three —Freedom, Margaret Ballard and a pretty little button of a bloom, Powder Puff. Little Pink Lady was shown by Mr. Wells and the Chalk Hill Nurseries, a dwarf-growing semi-double with rose-pink flowers. It is not quite a novelty, but it is next door to one. Except, of course, that names cannot be changed, it would have been very appropriate to have called Little Boy Blue and Little Pink Lady, General and Mrs. Tom Thumb.

DAHLIAS.

Dahlias and chrysanthemums have suffered through the bad weather of the last few days perhaps more than any other flowers. Wind and torrential rain dashed to the ground not only many choice blooms, but to a certain extent the hopes of the growers also. In spite of this set-back a large number of

Digitized by Google

dahlias and a few chrysanthemums were exhibited by various firms. Only a few singles of either flower were to be seen. The great variety of form and the wide range of colour of the countless varieties of the dahlia made the stands some of the most effective and most admired in the Show. Messrs. Dickson and Robinson exhibited some very fine dahlias. Augustinus, a huge lilac rose, and President Wilson, a brilliant scarlet both of the decorative type, the cactus-flowered F. W. Fellows and Edgar S. Jackson, together with Lucius, the attractive orange single, which is very effective for table decoration in artificial light, were the most outstanding among this group. Messrs. Dobbie and Co. had an interesting collection of all kinds. Many of the new varieties of the miniature peony-flowered dahlia were seen. The popularity of this type is increasing rapidly, owing to its usefulness for bedding purposes. Dazzle, brilliant scarlet; Our Annie, shrimp pink; Picture, orange flame, were a few representative of this class. Pompon dahlias, such as Little Jim and Nerissa, as well as Ben Lomond, Feodora, Rosella Amos, all handsome decorative dahlias, were among the first-class exhibit of Messrs. Dobbie and Co.

Messrs. J. Cheal and Co. showed many excellent dahlias, including both the star and mignon types. The best varieties were Dragoon, Orange King, Queenie, Edward Jackson, Luna and a 1925 novelty called Charlwood. Messrs. Carter Page staged a large collection, among which were some varieties not seen on other stands. Berengaria, Emblem, Emma Groot, Johan Mensing, Rona, Christine Prior, and Radium were outstanding. The dahlias shown by Mr. J. Riding were of great size. Good specimens of Pride of Berlin, Noble, Rodney and an excellent 1926 novelty named Reginald Godfrey were exhibited by this grower.

Messrs. J. Stredwick and Co. showed a large number of fine cactus and decorative dahlias, such as Ballet Girl, Jack Hobbs, Henry B. May, F. W. Fellows and Berengaria. Messrs. C. Turner and Co. staged a varied collection which was much admired. Flambeau, brilliant red, was most attractive, and Sonia, Golden King, Marianne, Trixie, Sulphurea and Roy Hay were in good condition. Peach, a delicate rose charm dahlia, Border King, Edgar S. Jackson, My Lady and Tipsy, were noted on the stand of Messrs. W. Treseder, Limited. Beautiful blooms of Rosella Amos, A. Rawlings, Fred. W. Ransome, and Stella were shown by Messrs. D. Prior and Son, Limited. A well staged dahlia group was put up by Mr. H. J. Jones, who included the varieties Jersey Beauty, J. van Citters, Amber King and Mary Copeland, among his collection. Joyce Goddard was a delightful yellow and orange cactus dahlia shown by Messrs. Jarman and Co. Mrs. Alfred Harvey and Mariette, were shown by the above firm. Dahlias were also exhibited by The Hemsley Nurseries, Messrs. J. T. West and Messrs. W. Cutbush and Son.

CHRYSANTHEMUMS

Chrysanthemums were shown by three firms only. The exhibit of Messrs. Keith Luxford and Co. was well arranged and the blooms in excellent condition. In the centre of the group Phœnix, a bright scarlet bronze, made a good contrast against the vivid yellow of New Cranford. Chocolate Soldier, Goldfinder (one of the best early yellows), Mary Mason and September White were much in evidence. Bold groups of Almirante and Pink Delight were shown by Mr. J. W. Forsyth. Mr. William Yandell selected some of the best early varieties, such as September Glory, Royal Salute, Dolores, Hesperus, Salmon Profusion and Horace Martin, for his exhibit of chrysanthemums. A very good selection of violas were shown by the same grower.

GLADIOLI.

Gladioli in the most beautiful colouring were exhibited by several firms. The handsome large-flowered varieties, as well as many new primulinus hybrids were much admired. An excellent collection was staged by Messrs. Austin McAslan and Co., who included some fine new varieties. A brilliant splash of colour was produced by Red Emperor, while Master Wietse, Mahony, Yellow Hammer, Clemenceau and Gipsy Girl formed effective patches of contrasting shades. Some of the primulinus hybrids, such as Orange Brilliant, Salmonea and Atalanta, were very dainty. Interesting hybrids of unique colouring were shown by Messrs. Lowe and Gibson. Rose Ash, Baron J. Hulot, Byron L. Smith, Ulysses, Tragedy, Pride of Lancaster and Field Mouse, together with Sapho, a gladiolus of uncommon colouring, and Kingfisher, a fine seedling, are only a few of the good varieties shown by this well known firm of gladioli hybridists.

The quality and size of the gladioli shown by the Orpington Nurseries were very noticeable. Perfect spikes of Pink Perfection, Blue Peacock, Schwaben, Princeps and Duchess of York were on show. A well arranged exhibit of gladioli was staged by Messrs. R. H. Bath, Limited: Romance, Gallieni, Frau Dr. Hauff, a handsome scarlet, and Par Excel were noted. Excellent groups were also staged by Mr. A. Edwards and Messrs. Bakers. These included a number of well grown and interesting varieties. The former exhibitor was handicapped by the fact that his apparatus for showing was not delivered by the railway company until the second day of the Show.

CLEMATIS.

That the present day varieties of clematis are practically continuous bloomers was fully evident from the large quantity of flowers borne on the excellent plants at the Show, for these were equally as attractive as at mid-summer. Messrs. G. Jackman and Sons, had a great many trained plants. Crimson King was of rich colouring, Lord Neville is a grand medium blue, Duchess of Sutherland is a bright red with a sheen of plum purple, while the Countess de Bouchard was the most free flowering of them all, though the soft pink flowers are not quite so large as the others, but the general effect is excellent.

Many similar varieties were shown by Messrs. L. R. Russell, Limited, who associated their clematis with trained plants of the ornamental vines and bordered the group with heaths, fuchsias and other shrubs. Among their clematis, Marie Boisselot, white; Mr. Kenneth, silvery lavender; Jackmanni superb, a rich purple; Gloire de St. Julien, sparkling French white; and the ever popular Nelly Moser, were very fascinating.

SUCCULENTS.

The South African Railways showed a most interesting exhibit of succulents from the Karroo, collected and shown by Mr. Frith. This is probably the finest collection that has ever been seen in the British Isles. Numbers of euphorbias, cotyledons, crassulas and gasterias were to be seen. There were several specimens of the elephant's foot plant, or Testudinaria elephantipes, which has an extraordinary corm like an elephant's foot. Mr. Frith deserves every credit for this extraordinary exhibit, which has been shown at Wembley throughout the season. He also showed a new species of watsonia with magenta flowers which is so far unnamed. Mr. Sydney Smith also staged a fine exhibit in pots, including miniature gardens planted with tiny succulents which make attractive decorations for those who like something out of the way for house decoration.

SUCCULENTS ON THE EXHIBIT OF THE SOUTH AFRICAN RAILWAYS

CARNATIONS.

Large exhibits of carnations were staged by the principal carnation growers. Mr. C. Engelmann had a striking group, including the newest and best varieties. Mrs. Hamilton Fellows, Red Laddie, Shiela Greer, Improved Ward, Eileen Low, Red Peerless and the

Digitized by Google

new glowing cerise Betty Loo were a few of the finest shown.

Perpetual, perpetual border and Allwoodii carnations were exhibited by Messrs. Allwood Brothers—Phœbe (a salmon red self) and Nora, two new varieties, together with Bryan, Barbara and Annwell, were the best of the Allwoodii. In the group of perpetual border carnations Taffata was noticeable, and in the general collection of perpetuals Cameron, Shot Silk, Beauty of Durham, Coral Glow, Edward Allwood, and Chintz were carnations good in colour, shape and form.

Messrs. Stuart Low and Co. had a seedling carnation of unique colouring called Nerablue. It was a very dark carnation, which at a distance looked almost black. Lady Hindlip (an attractive white-ground variety pencilled with red), Improved Mrs. Ives, Duchess of York, Lady Iverforth and White Pearl made effective groups on this stand.

SHRUBS.

As usual, shrubs with berries and autumn colouring were a feature at the Show, and this section undoubtedly proves that many gardens would be improved in the autumn by the inclusion of tinted and berried shrubs. Messrs. Hillier's exhibit was very representative and included many rare species, among them Berberis Sieboldii with sealing-wax red berries and a handsome red stem; and Pyrus Vilmorinii, one of the most graceful of the genus, with scarlet berries. There were numerous maples, crabs, berberis and ornamental vines also to be seen on this stand. Messrs. Cheal staged a number of fine seedling berberis, maples and crabs. The most noticeable plant on their stand was a magnificently coloured Euonymus alatus, which formed a cataract of old rose. Messrs. Fletcher Brothers displayed conifers and berried plants. The young conifers showed particularly good cultivation. Messrs. Cuthbert had a quiet and excellent arrangement of conifers and lilies with a few shrubs with autumn tints. The bronze colour of the leaves of Azalea Hinodegiri was particularly good. Many interesting shrubs and trees were to be seen on Messrs. Wallace's stand. The colour on the seedling mollis azalea Bouquet de Flore showed that the beauty of the azalea is not only during the flowering season. The colour scheme of this stand was particularly effective. Mr. Reuthe, as usual, showed many rare plants in his collection. Among them were Nothofagus fusca and N. Cliffortioides, and Leucodendrum argenteum. Messrs. Charlton staged some fine specimens of fruiting crabs among their collection of trees and shrubs, and also such interesting plants as Corokia virgata and Billardiera longifolia. The Orpington Nurseries showed conifers and a general collection of well grown shrubs, among them several interesting varieties of hibiscus, a useful late-flowering shrub in the south.

Hollamby's Nurseries had a striking exhibit of Pyracantha Lelandii Fireflame, shown in pots, which were exceptionally well berried. These were all raised from cuttings, which is probably the reason for the abundance of berries on such small plants. Mr. Notcutt, as usual at this season of the year, staged a fine exhibit of shrubs with autumn tints or with berries. Berberis, pyrus and cotoneasters were effectively staged. Bays and clipped trees were shown by Messrs. Robert Green, Messrs. Harrods and Mr. John Klinkert.

ALPINES.

Messrs. Rogers staged alpines along with dwarf conifers in pots and a few dwarf succulents. The red and white forms of Menziesia polifolia were noticeable, and also the fine purple Verbena venosa. Messrs. Maxwell and Beale showed a small heath garden with examples of all the attractive autumn-flowering varieties. This firm also staged a rock garden showing plants that flower in the autumn, among them the good scarlet Mimulus cupreus Brilliant and Gentiana Freyniana. Mr. Gavin Jones staged well grown alpines and dwarf conifers in pots. Mr. F. J. Wood showed a fine collection of autumn plants for the rock garden. These were very well arranged, and included such plants as Hypericum reptans, a dwarf St. John's wort that is always worth growing, Polygonum Brunonis, Gentiana sino-ornata and Fuchsia pumila. Mr. Clarence Elliott staged one of his excellent alpine scenes which are always such a feature. Little cyclamens were charmingly placed among rocks along with Gentiana sino-ornata, while colchicums, crocuses and little potentillas popped up out of the moss of an alpine pasture. Messrs. Bowell and Skarrett staged hardy plants including asters and alpines. Sedum spectabile atropurpureum was in fine flower, and several colchicums were also notable.

ORCHIDS.

The only groups of orchids were staged by Messrs. Black and Flory, Messrs. Cowan and Co., and Messrs. Stuart Low and Co.

CATTLEYA AMABILIS ALBA, LOW'S VARIETY (labiata × Warscewiczii).—This showy hybrid carried a spike of three large flowers having broadly developed, pure white sepals and petals, the roundly formed labellum bright purple over its entire frontal area except for a narrow whitish margin. Award of merit. From Messrs. Stuart Low and Co.

CATTLEYA MIMOSA SUPERBA (Venus × triumphans).—A particularly attractive hybrid with a large flower of bright golden yellow colour. The elongated labellum has the broadly developed apical area of purplish ruby colour, the central area with golden venation, and the comparatively small lateral lobes incurved over the whitish column. Award of merit. Exhibited by Messrs. Cowan and Co., Southgate, N.

CATTLEYA TAGUS VAR. KING GEORGE (Rhoda × King George).—A fine addition to the yellow section. The flower has well developed petals set in up-standing style and of bright lemon yellow colour, as are the sepals also; the labellum of intense crimson purple, crisped at the margin, and with obscure veining in the throat. Award of merit. Staged by Messrs. Black and Flory, Slough.

LÆLIO-CATTLEYA PROFUSION VAR. ADRIATIC (L.-C. Serbia × C. Hardyana).—A splendid example of this free-flowering hybrid. The vigorous plant bore a spike of four large flowers of bright rosy mauve colour, the expansive labellum purplish and with a light yellow area on the inner area of each lateral lobe. Award of merit. Shown by Messrs. J. and A. McBean, Cooksbridge, Sussex.

CYPRIPEDIUM FAIRRIEANUM BODNANT VARIETY.—A vigorous plant with two flowers larger than the type, the dorsal sepal being 2ins. in width. It had been unusually well cultivated since the time when it was imported five years ago. Cultural commendation. Exhibited by Lady Aberconway and the Hon. H. D. McLaren, Bodnant, Tal-y-Cafn (gardener, Mr. F. C. Puddle).

FRUIT AND VEGETABLES.

No exhibits of fruit or vegetables were allowed in the main hall at Holland Park; in the gallery only positions for such exhibits were granted. The number of stands in the gallery was very small. Healthy figs fruiting in pots were shown by Messrs. Stuart Low, and good collections of hardy fruit were exhibited by Mr. E. J. Parsons and Studley College, Warwickshire.

A large collection of apples, both dessert and culinary sorts, was exhibited by the Barnham Nurseries.

GRASSES.

Mr. MacDonald again occupied the centre with a grass lawn dotted with little beds of fancy grasses and heather, with a few berberis to give colour. This was a notable exhibit for the clean appearance of the lawn grass.

NEW AND RARE PLANTS.

BEAUFORTIA DECUSSATA.—Although this is an old garden plant, it was introduced from Australia in 1803 and found a place in a fair number of greenhouses, it is now a very rare plant in this country. Its beauty and uncommon appearance attracted considerable admiration. The illustration in the Botanical Magazine fails to do justice to the beauty of the flowers which are very like those of the better known "Bottle Brush Tree," except that they are coloured bright orange, with a suggestion of scarlet. They cluster around the stems of the shrub in the same manner as in a metrosideros (callistemon), and the radiating filaments are longer. The opposite leaves are small, stout and ascending. It is a charming plant for the cool house and it continues decorative for a long time. Award of merit. Shown by the Rev. A. T. Boscawen.

CARNATION SHOT SILK.—This is not everyone's carnation, but will appeal rather to those who like a fancy of uncommon colouring. It is a greenhouse variety and appears to produce the purplish-rose flowers, which have occasional scarlet splashes, very freely. It is slightly fragrant. Award of merit. Shown by Messrs. Allwood Bros.

CHRYSANTHEMUM CRIMSON CIRCLE, C. FIRE CREST, C. MAYFORD WHITE, AND C. PINK DAME.—These four varieties, which received awards of merit, were shown the previous day before the National Chrysanthemum Society (see page viii).

ERICA VAGANS MRS. H. E. MAXWELL.—A compact and bright flowered heath which in general appearance is very like a richer coloured E. carnea. It would be very effective in the rock garden or the heather bed. Shown by Messrs. Maxwell and Beale.

GLOXINIA BEACON.—A gorgeously beautiful variety which is particularly floriferous. The erect flowers are of rich crimson colour which is slightly lighter at the margins and darker in the throat. Award of merit. Shown by Messrs. Sutton and Sons.

G. MAUVE QUEEN.—A handsome bright mauve variety of the same good strain as the above. The flowers have creamy tubes and are a trifle paler on the margins. Award of merit. Shown by Messrs. Sutton and Sons.

KNIPHOFIA W. G. MILLS.—A very vivid red hot poker with a long spike of bright coral flowers. It is a welcome addition to these showy border plants. Award of merit. Shown by Messrs. Bakers, Limited.

MELICYTUS RAMIFLORUS.—A very uncommon evergreen shrub which is said to become about 20ft. high. It has large shining green leaves very like those of Phillyrea Vilmoriniana and has loose clusters of whitish flowers around the branches. The blooms are succeeded by small shining blue berries, carried on relatively long stalks. Award of merit. Shown by the Rev. A. T. Boscawen.

PENTAS PARVIFLORA.—A sub-shrub from western tropical Africa, which bears, when quite dwarf, small heads of flame-coloured flowers, very like those of the bouvardia. It requires warm house treatment. Award of merit. Shown by Mr. Wm. van de Weyer.

SCHIZANDRA RUBRIFLORA.—A Chinese shrub of doubtful hardiness, whose chief interest lies in the hanging clusters of crimson fruits which usually continue for a considerable time. The dark green, ovate-lanceolate leaves are of roughish texture. Award of merit. Shown by the Hon. Vicary Gibbs.

Do YOU know PARSONS

WORCESTER BERRY?

If not, you have yet to learn of one of the most useful berries in cultivation;

and WHY?

It has **proved its worth** as a decided marvel in berry-bearing fruits, viz.:

As a Cropper.

As a Jam or Jelly Fruit, or for Tarts.

As a resister of Big Bud (or Mite) and Mildew.

Owing to heavy demands I have only a limited quantity, but offer, as far as my stock will permit, as follows:

Bushes or Single Cordons ..	2/6 to 3/- each
Extra Strong Fruiting Bushes ..	3/6 to 5/- each
Double and Treble Cordons or Fan Trained, for Walls, Trellis, etc., Extra Strong Fruiting	3/6 to 5/- each

Packing and Postage extra, viz.:
1 plant, 9d.; 2 do., 1/-; 3 do., 1/3; 4 do., 1/6; 6 or more, carriage paid.

READ THIS.—

WORCESTER, *September 4th*, 1925.

Dear Sir,—You will remember me buying a bush of your Worcester Berry 5 years ago. I have picked a fine lot from it the past three seasons, but this year has eclipsed everything and has yielded 26½ lbs. We are all very fond of the jam and also in tarts and pies, and in my opinion there is nothing to touch it in Berry Fruits.—Yours faithfully, T. T. JONES.

My List includes ALL THE BEST in APPLES, PEARS, PLUMS, etc., and my Worcester Grown FIBROUS-ROOTED Trees may be relied upon for BEST RESULTS and QUICK RETURNS.

EDWARD J. PARSONS, F.R.H.S., Fruit Specialist
Barbourne Nurseries, WORCESTER

The Executors of the late

ANTHONY WATERER

beg to offer

Standard Trees

in great variety, consisting of

LIMES, NORWAY MAPLES, ELMS, etc., etc.

EVERGREEN & DECIDUOUS SHRUBS, viz.:

Box—Green and Variegated, 3 to 8 ft.
Hollies—Common, 5 to 8 ft.; Variegated and Green varieties, 2 to 6 ft.
Thuiopsis borealis, 10 to 12 ft. Cupressus Lawsoniana, 12 to 14 ft. Cedrus atlantica glauca, very fine, 10 to 14 ft. Osmanthus, Phillyroeas, Spiræas, Lilacs, Viburnums, etc.

GOLDEN YEWS

A Magnificent Stock in all shapes and sizes from 2 to 10 ft.

PRIVET, Common and Oval-leaved, QUICK and HORNBEAM for Hedges.

AZALEAS - - - 2 to 5 ft.

RHODODENDRONS, without doubt the finest stock in the trade of named varieties, 2 to 6 and 8 ft.

RHODODENDRONS, Standards in best named varieties.

HARDY HEATHS in great variety and a good general nursery stock.

Catalogues ready shortly.

Enquiries and Inspection Invited.

Allen's ROSES

Guaranteed from East Coast Rose Fields.

OUR FULL DESCRIPTIVE CATALOGUE IS NOW READY POST FREE. SEND A CARD FOR IT TO-DAY.

Contents include:—
Critical descriptions of over 500 varieties.
Six superb coloured illustrations.
Special offer of Collections.
Survey of Novelties.
Select Lists of varieties.
Cultural Hints, etc., etc.

A HANDBOOK NO ROSE GROWER CAN AFFORD TO MISS.

TO CIRCULARISE OUR CATALOGUE WE ARE OFFERING FOR A LIMITED PERIOD THE "SUPERB" COLLECTION OF 12 OF THE FINEST VARIETIES GIVEN BELOW FOR OCTOBER DELIVERY. PRICE 12/- CARRIAGE PAID. Cash with Order. SEPARATE PRICES ARE GIVEN, but where Collection is divided 1/- must be added to remittance for carriage. NOT LESS THAN SIX ROSES SUPPLIED FROM THIS SPECIAL OFFER.

BETTY UPRICHARD, the finest rose in commerce, salmon and orange scarlet	1/6
COL. OSWALD FITZGERALD, fine deep crimson ..	1/3
EMMA WRIGHT, pure orange	1/3
ETOILE DE HOLLANDE, deep scarlet, richly fragrant	1/6
GOLDEN EMBLEM, deep golden yellow	1/3
INDEPENDENCE DAY, apricot orange	1/3
LOS ANGELES, coral flame	1/3
MME. BUTTERFLY, flesh pink, fragrant	1/3
MRS. HERBERT STEVENS, pure white	1/3
SUNSTAR, orange tipped cherry pink	1/3
THE QUEEN ALEXANDRA, vermilion and old gold	1/3
WM. F. DREER, yellow orange and apricot shades ..	1/3

The entire collection for **12**/- *carriage paid. No Rubbish. All first-class selected varieties in Tip-Top quality plants. All guaranteed Norfolk grown. Order now and ensure early delivery.*

The Household Collection of Bulbs for Fibre Culture

15/-

Carriage Paid.

This collection is made up of bulbs suitable for growing in fibre to make a succession of bloom from January to end of March. It contains:—

6 Miniature Hyacinths, Pink,
6 Miniature Hyacinths, Blue, prepared for early flowering,
18 Crocuses, two varieties,
Varieties of Daffodils and Narcissi, 6 bulbs of each,
6 Polyanthus Narcissus,

and sufficient prepared fibre to grow them in.

We specially recommend this collection to those who have not previously grown bulbs in bowls, because the varieties we have selected are thoroughly reliable for fibre culture.

GARDEN TECHNIQUE

Notes on the Technical Side of the Garden and the Cultivation of Plants.

GARDEN RUBBISH.

EXCELLENT in itself is the advice so frequently given that lawn mowings, tree leaves, tops of root vegetables and waste vegetable matter generally should be consigned to a heap to rot down; humus and plant food is thus obtained which, either on heavy clay soil or sandy, gravelly or chalky soils will be of quite considerable value, but is less beneficial for old garden soils which are already well supplied with humus. The introduction of the proprietary article "Adco," is of great help in the direction of making the best use of vegetable waste, and so long as the rubbish is "clean," by which is meant that it is free from the spores or germs of disease, the eggs or pupæ of insect pests, and the seeds of weeds, the "Adco" treated rubbish heap will, for many garden owners, go far toward solving the problem of manure supplies.

There is, however, undoubted need for a word of warning even regarding so apparently simple a matter as the control of the garden rubbish heap. The value of humus has been extolled to such an extent that a widespread impression obtains that anything and everything that is embraced by the comprehensive title "Garden Rubbish," is good for manure, but it is of vital importance to bear in mind that the reproductive organisms of virulent plant diseases, and the eggs, larvæ and pupæ of innumerable insect pests are seldom killed or destroyed by the mere process of decomposition of the vegetable matter which serves as host for the pest or disease. One may see the falling leaves of roses distorted and withered by black spot, mildew and rust; the haulm of potatoes blackened by Phytophthora infestans or disfigured by mosaic; cabbage stumps gnarled and knotted with club root, and even weeds laden with minute eggs of various aphides and yet all this filth and pestilence is allowed either to lie about on the soil or to take up snug quarters on the rubbish heap, where the period of inactivity will be passed and from whence the active life will next season emerge to pursue once more a merciless warfare upon tender young growth of cherished plants.

At the end of the fruit season one may generally find in orchards rotting fruit that fell from the trees in consequence of insects or disease. The fruits decay but the diseases and insects survive. Even the manure from pigs that have eaten diseased fruit, potatoes and other vegetables, has been proved by microscopic inspection to be infested with the germs or spores of the diseases, and many of these dormant organisms appear capable of defying strong fungicides and insecticides. Deliberately to harbour rubbish that is known to be thus swarming with the destructive enemies of plant life is sheer folly; the one and only safe measure to adopt with such filth is to cremate it.

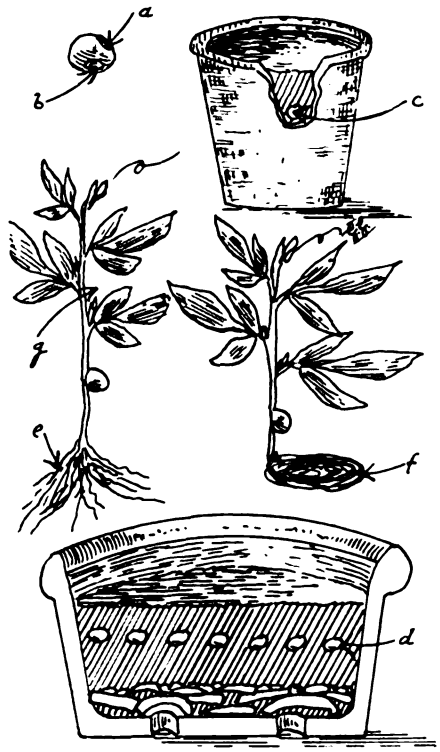
An incinerator as well as a rubbish heap is a necessity in the garden and at the present season of the year the incinerator should be kept busy in the interests of hygiene of the garden and orchard.

There should be little need to fear trouble from the mowings of a healthy lawn, and all leaves and herbage of clean, healthy plants should certainly be "Adcoized" and made profitable, but the additional quantity of manure obtainable from pestilent rubbish will be very dearly bought at the price of another generation of pests or a further outbreak of troublesome disease among one's plants or crops.

The notion is commonly held that a dusting of lime will put all things right, but beneficial as lime undoubtedly is, it is unequal to the entire destruction of dormant garden foes; were it not so we may safely say many gardens where lime is liberally used would have been freed from foes. Fire is the one reliable means of extinction of stubborn enemies of the garden, and although fire consumes the humus forming matter of the rubbish, it leaves ash which is clean and wholesome plant food of high value. More careful control of the rubbish heap and more regular use of the incinerator would go far toward producing a clean bill of health in the average garden.—A. J. MACSELF.

AUTUMN-RAISED SWEET PEAS.

THE flowers are still fresh on some plants growing outside, but the time has come again when we must sow seeds for the earliest crops, under glass and outside, next year. In some gardens sweet peas do not bloom



well after the end of July, in others, my own included, plants raised in September continue to flower outside till the following September, and do better than plants raised from seeds sown in the open ground in spring. It is advisable, however, to sow in the autumn and also in the spring. Some varieties require chipping to ensure germination. This should be done with care; the light-coloured indentation, *a*, must not be cut, as the new shoot grows there, but as shown at *b*. If one seed is sown singly in a pot, sow it as shown at *c*, but if many are sown in a large pot or pan, sow the seeds as shown at *d*. It is advisable to sift the soil through a half-inch mesh sieve, to drain well the large pots and to place the seeds about 1in. apart on the watered soil; then cover with rather more than 1in. of the dry soil. Do all this before the pots are placed in the frame, then you will avoid moistening the dry lime scattered inside the frame to guard against slugs. The resultant plants should be potted singly at an early stage, then the roots readily part from the sifted soil without breaking, shown at *e*. Do not leave the plants too long in the seed pots to become pot or root-bound, as shown at *f*. Take care of the basal side shoots *g*; grow the plants hardily.

SPRING CABBAGE, COLEWORTS AND EARLY CAULIFLOWERS.

COLEWORTS raised from seeds sown in May and transplanted in firm, well manured ground will yield some very useful heads during the autumn and early winter, thus following the summer cabbages. The later crop of plants, resultant from seeds sown in summer-time, will prolong the supply. These crops should now receive a little special attention, not in the way of feeding, as it is the wrong time of the year to force growth of any kind outside, but in the matter of a general cleaning—freeing the ground of weeds and the plants of faded leaves. In the case of the later batch of plants it is advisable to draw up soil to the rows now, burying the stems as much as possible. When frost injures winter greens it is, mostly, that part of the stem just below the basal leaves. The wet weather that sometimes comes in the autumn causes the stems at this point to become sappy and swell considerably, and then a severe frost may, when the thaw occurs, split the stems. The present is a good time to get the cabbages planted out in their permanent quarters. Again, I would like to say do not try to force the growth forward this autumn; nevertheless, it is advisable to apply manure, and I recommend it to be put in not nearer than 7ins. to the surface—from that point downwards. The roots will not come into direct contact with it this year, but early next year, when the plants are needing some support when the hearts are forming. The earliest batch of cauliflower plants should be planted in a cold frame or similar position, so that a light covering can be placed on during severe weather. In the meantime their permanent quarters should be dug and manured.—G. G.

WINTER PROTECTION FOR OUT-DOOR PLANTS.

OF course, I am now referring to plants that are sufficiently hardy to withstand an ordinary winter without any special protection, but which, if exposed to a severe frost, would be badly damaged. I have seen splendid plants of Escallonia macrantha 14ft. high, nicely covering a south wall, cut to the ground-level in a severe winter. If the green boughs of some hardy shrubs or trees had been freely mixed with those of the escallonia the latter would have survived. Jasminum primulinum should always have some protecting material placed over it in very frosty weather. In counties north of London it would be advisable to do this even where the plants are growing under an open verandah. Of course, scrim or tiffany suspended by rings or string loops from nails driven into walls over choice plants on walls will keep out many degrees of frost. I prefer to nail the sheets of scrim to light wooden frames, as the latter are so quickly placed in position; it may be late at night, and it is kept well away from the leaves. In this way violets in open beds may be protected, the sheets of scrim being placed on forked stakes driven into the ground and left 1ft. above it. Iris stylosa may need such protection, also Christmas roses, but the latter, in addition, should be surrounded with dry ashes or coarse sand as well. In the herbaceous border there

Digitized by Google

are many subjects, such as the delphinium, that will need the protection of dry ashes against slugs as well as frosts, and materials should be prepared before frosts come.—GEORGE GARNER.

LETTUCES FOR WINTER.

LETTUCES are cultivated throughout the summer months in most gardens, quite often upon the soil thrown up from out of the celery trenches, sometimes between the lines of other vegetable crops, or in any odd corner of the garden, and in these positions the plants grow quite well and good lettuces are obtained. The idea of growing the plants in these places is to utilise all available space in the garden to the best advantage. It may be interesting to state that market men grow their early crops under glass, between the lines of young tomato plants and under these favourable conditions fine lettuces are produced.

Those, however, who wish to have lettuces throughout the winter should have good sized seedlings ready to set out now. These should be planted either in a frame or near to the base of a sunny wall on a sheltered border, where some protection can be given the plants should severe weather prevail. Lettuce plants in frames when once properly established should be well aired, so that surplus damp is expelled as much as possible and the plants kept hardy, while mats or other protective material should be spread over the frame lights in very severe weather.

From an August sowing of a variety called Hardy Green Hammersmith, we set out the seedlings in a frame early in October, and started cutting at the end of January. This variety is stated to be the best for winter use. We have in the past sown Neapolitan —another cabbage variety—and Hardy Green Hammersmith at the end of May and noticed in September that Hardy Green Hammersmith or what were left of them had pushed up their flower stems, while plants of Neapolitan, both those which had been pricked off and those which were allowed to grow in the seed bed, showed no sign of flower stems at the same period, and both varieties were grown on the same border. The conclusion is that Hardy Green Hammersmith is a quicker maturing kind, and so more suitable for growing in winter, when climatic conditions are not so favourable to rapid growth.—DAVID ARMSTRONG, *Midlothian*.

LILIUMS FROM SEED.

LILIES are among the most beautiful of bulbous plants, and are so easily grown from bulbs, that it is hardly surprising that but few people turn their attention to raising them from seeds. They can be so raised without difficulty, however, and some nurserymen offer seeds of quite a large number of both species and hybrids. Lilies have flowered in less than two years from the time of sowing the seeds, and I have seen L. formosanum, an alpine variety of philippinense, collected by Mr. W. R. Price in Formosa, producing flowers in the seed pan. This lily is somewhat similar in shape to L. longiflorum, white in colour, and possesses a good constitution. A fine lily of Chinese origin is L. regale, the centre of the flower is flushed with yellow shading to white at the outer edges. The colour of the superb L. sulphureum is described in its name, and the hybrid L. sulphur-gale, is intermediate between its parents, L. sulphureum and L. regale. The orange L. Henryi, the vivid orange red L. Willmottæ, the purple L. Martagon with its white variety album, and others have all been successfully raised from seeds. The period that must elapse before the seedlings attain flowering size will largely depend upon the treatment afforded, but as a rule three years is about the time for flower spikes to appear in any quantity. Seeds may be sown either in autumn or in the spring, and I have found a cold brick pit the best place to raise the seedlings. Three or four inches of light soil is placed in the pit, and the seeds are sown thinly and evenly over the surface. Just cover the seeds with sandy soil, and care must be taken to prevent the compost becoming very wet or the seeds will decay. Until germination is effected the lights can be covered with a thin canvas or similar material. When the seedlings have made a third or fourth leaf, they can be pricked off in a similar pit or frame, and here they will remain for some months to form nice sized bulbs. Where only a few are grown, the seeds can be sown in boxes, and germinated in a cool greenhouse, while a sheltered border outside is also suitable, but here the seed beds are better if protected with hand lights until the seedlings are well advanced.—T. W. B., *Chepstow*.

MANURES FOR THE GARDEN.

AT this season of the year the farmer turns his thoughts, generally, to the matter of ploughing and manuring his land. So, too, will the wise gardener. For nearly a whole year he has been taking crops from the garden; these cannot be obtained without absorbing nutriment from the soil, and before the latter is again cropped its larder must be replenished. Basic slag can be applied in the autumn with advantage; indeed, it is the best time for its application, also for lime, etc., and animal manures where heavy soils obtain. But I know how difficult it is for many owners of gardens to obtain animal or farmyard manure and, as most soils require humus in them, what is to be done? What substitute can be used? I have to buy all my manure, farmyard and artificial; but as I am not able to procure sufficient from the farmyard, I use Wakeley's Hop Manure, and with excellent results too. I generally use it from autumn to March, and throughout the summer in smaller quantities and for mixing with composts for potting. At the end of a year I can find the manure in a well rotted state in the soil, and the latter crumbles nicely around it. I have used it as a surface mulch, but found it acted best in this way when just lightly covered with ordinary soil to keep it in position as it dries in the sun. For onions, leeks, celery, etc., it should be buried well below the roots when planted. All organic manures should be kept under cover during the winter. Sheep, goat and poultry manures should be added to the soil in a dry state in spring.—HAMPSHIRE.

CORRESPONDENCE

ALSTRŒMERIA AURANTIACA.

SIR,—In reference to your correspondent under "Interesting Answers," in your issue of September 19th (page 534), with regard to Alstrœmeria aurantiaca, I had exactly the same experience. I bought roots from thoroughly reliable nurserymen, but they did no good and very soon died. I then purchased packets of seeds of three varieties and sowed them in a 6in. pot in a warm greenhouse in January. The plants were 4ins. or 5ins. high in June and the pots full of roots and I planted them straight into the border. They all flowered a little the first year and ever since have gone right ahead, and the only difficulty I have is to keep them in bounds. I have one clump under pine trees about 10ft. to 12ft. across and another clump under a north wall, where the plants have come up on the other side of the path.

If your correspondent will raise the plants from seed he will have no difficulty, but they usually greatly resent root disturbance.—GEO. D. DAY, *Hunts*.

COLOUR NOMENCLATURE.

SIR,—What an excellent and much needed article was yours on "Colour Nomenclature," and how wise its suggestion of some twenty-four names. There are colour charts, both French and American, and books like Mrs. Francis King's "Well Considered Garden," use them; but they are somewhat elaborate, and for ordinary usage something simpler, but well defined, would be gratefully received. "Gentian" blue and primrose are clear and unmistakable—surely more can be found like these. I have heard Iris tectorum called both "China" and "Delft" blue—both obviously searching to render a definite impression. But "salmon"!—sometimes it is the colour of raw tomato and again a washed-out, nondescript, pinkish-yellow. And "mauve"! what is the standard flower of "mauve"?

I should say *magenta* was definite, but not half enough used; so many things described as "old rose," "glowing pink," "soft mauve," etc., are plain "magenta"—indeed, one sometimes feels in desperation that it is the colour of nature, to which all things return. If "old rose" means anything, it should mean the very soft, almost ashen colour seen in Persian carpets, not something garish akin to magenta. What anarchy rules in the descriptions of yellow roses! What would you call Golden Emblem, Sovereign, Lady Roundway? I use "golden yellow" to distinguish them from "pure" or "daffodil" yellow, such as Souv. de Claudius Pernet, Golden Ophelia or Constance, but obviously there is need of order here, as well as in dividing pinks like Mme. Abel Chatenay, Earl of Warwick, Dr. Joseph Drew, which are warm and soft, from pure and "cold" pinks like Lady Ashtown, Radiance or Premier. Iris especially lend themselves to impressions different from catalogue descriptions, which, while accurately giving the colour of falls and standards, often fail to give the *general effect*, so necessary when grouping different ones together. One is driven to going around a garden with a note book and making one's own classifications Troost, Jussien, Œnid de Valery Mayet, Khamsin, go together; Loute, Sceptra, Opera also—and so on, renouncing any attempt to describe them individually. Eduard Michel is called "rich petunia violet," and Caprice "soft pink-violet," yet I should call both magenta.

Who could put order into red tulips, and set apart those which are really red, with no tinge of blue, like King Harold or Isis, from those which are half-blue or half-pink, like van Poortoliet or Farncombe Sanders? Reds that "blue," pinks that "magenta," yellows that "lemon," all cry for clear divisions. May THE GARDEN succeed in giving them one.

This is, of course, the cry of the very plain amateur gardeners; the great ones do not need these aids, but the makers of catalogues do.—AN ITALIAN READER.

FREESIA CHAPMANII.

SIR,—My attention has just been called to some recent notes from Mr. van Tubergen, in which he questions the origin of the above as having been derived from F. aurea. I

THE GARDEN

VOL. LXXXIX.—No. 2812. OCTOBER 10, 1925.

Price Threepence. Yearly Subscription, Inland, 17s. 4d.; Foreign, 17s. 4d. Registered at the General Post Office as a Newspaper and for Canadian Magazine Post.
Editorial Offices: 20, TAVISTOCK STREET, COVENT GARDEN, W.C.2. *Offices for Advertisements:* 6–11, SOUTHAMPTON STREET, STRAND, W.C.2.
Entered as Second-class Matter at the New York, N.Y., Post Office.

LOUDON'S PLANTING

JOHN CLAUDIUS LOUDON, who was born in 1783, was rather a famous person in the horticultural world. He was probably the first man to be designated a writer on horticultural subjects. His best known works were the "Encyclopedia of Gardening," which was first published in 1822 and ran through several editions, and his "Arboretum et Fructicetum Britannicum," which was started in 1838 in monthly parts. The latter was a financial failure, and unfortunately so, for Sir W. J. Hooker said of it: "There is not a naturalist in Europe who could have executed the task with anything like the talent and accuracy displayed by Mr. Loudon." Both of these works, although moderately useful even to-day, are so out of date that they are more collectors' books than works of reference for the amateur horticulturist.

The object of this note is to bring out of the obscurity into which it has fallen a little book which nowadays is unknown. Few of those who are acquainted with it realise that it was written by Loudon, for it was issued anonymously. It was a volume of the Library of Useful Knowledge, and is called "Useful and Ornamental Planting," with an index published under the superintendence of the Society for the Diffusion of Useful Knowledge, London: Baldwin and Craddock, Paternoster-Row, MDCCCXXXII, 8vo, 151 pages. Even to-day it is an extremely useful little book, crammed full of information difficult to obtain elsewhere. In its day it deserved far greater credit than it obtained, for anyone might have been proud to cram so much useful information into 150 pages. Here is a sample from one of the opening paragraphs which is just as applicable now as it was ninety-three years ago: "Many thousands of acres now unprofitable to the owners and to the community, might, by judicious planting, be reclaimed, and rendered highly productive; and it may be safely affirmed, that there is hardly a spot of waste land in the kingdom so barren, which by the exercise of skill in planting, and selection of proper species of forest-trees adapted to the soil and exposure, might not be covered with profitable plantations."

The small section which deals with the structure and botany of the plant is the most out-of-date portion of the book and is almost useless. When Loudon comes to the different methods of raising fruit trees, he is on surer ground, and except that he gives first place to the oak, no doubt owing to its use in shipbuilding, there is much useful information to be gained on nurseries, layering, cuttings and so on. He then goes on to discuss the advantages and disadvantages of the four main methods of planting: first, slit-planting; second, holing or pitting; third, trench-planting; fourth, furrow-planting. The next chapter is devoted to soils, descriptions of the various types and the trees which are best suited to each type. Chapter VI deals with the culture of plantations, pruning, thinning and so on. Then follows one of the most interesting sections of the entire book, a note on the progressive increase of size or produce of wood in different species of forest trees with examples of remarkable trees. The various sizes are exceedingly interesting for purposes of comparison with specimen trees of the present day. Following are various lists and descriptions of forest trees, and the volume ends with a chapter on ornamental planting.

Among the lists is one giving the names of products of plantations. Probably most of these names are known to old woodmen, but many are strangers to me. Here are a few samples: bavins, smart-hoops, cooper's ware, edders, moot, shakes, gears or low faggots.

There are many interesting notes given in the list of forest trees and, indeed, the lists themselves are astonishing as a guide to the immense number of trees that were then obtainable. For instance, he mentions thirty-one species of ash, ten of alder, seventy-one of oak and so on. Doubtless many of these no longer exist as species, but a sufficient number are left to show what an extensive list there was to select from in the eighteen-thirties.

I shall conclude with quoting from a paragraph at the end of the book: "We have ourselves removed large trees without failure and have seen reason to conclude, that notwithstanding the careful preparation of the tree, the preservation of its roots and rootlets, and the careful adaptation of the soil, the success of the effort, and the immediate growth of the tree, will depend much upon its removal at the beginning of winter, and upon copious watering early in March, to be continued at least every fortnight during the first summer after transplantation."

There must be dozens of this little book to be obtained in second-hand book shops for a very few shillings, and very useful it is.

E. H. M. C.

AMONG THE ARTICLES IN OUR NEXT ISSUE WILL BE:

THE IMPORTANCE OF THE MODERN RAMBLER, by Walter Easlea.

PLANNING AND PLANTING A SMALL ROSE GARDEN, by George Dillistone.

THE POLYANTHA POMPON ROSES, by White Lady.

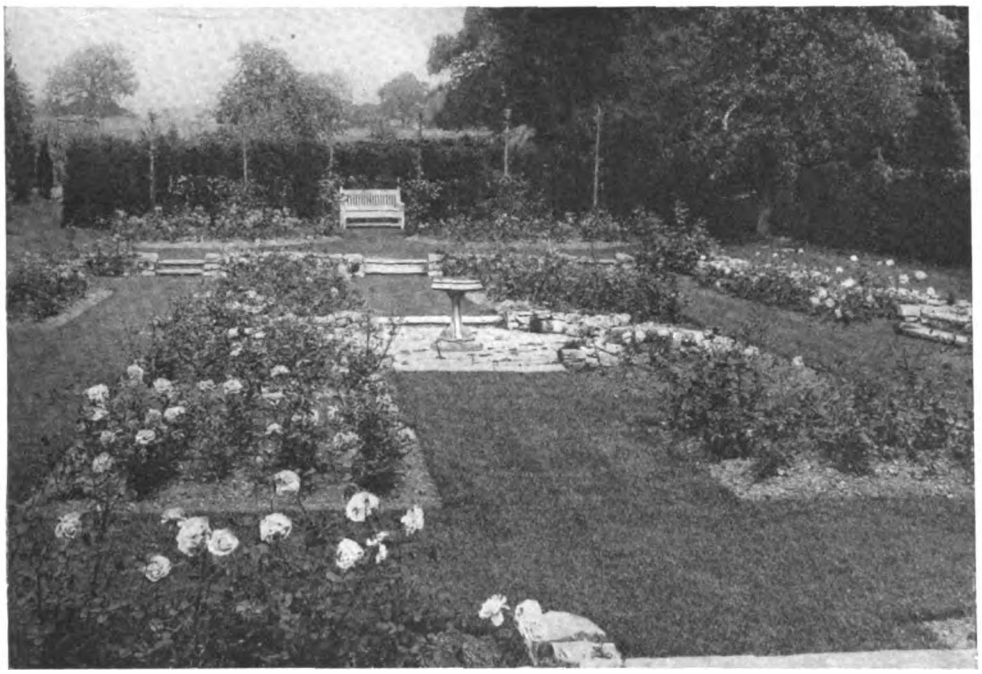
THE MAKING OF A ROSE GARDEN

BY HERBERT L. WETTERN.

THE orderly planning and development of a rose garden, as with so many other schemes of construction, is at the outset hedged about by certain limitations and restrictions, which tend to define its ultimate form and, despite the keenness and enthusiasm of the potential rose grower, it may not be possible for him to pick and chose with absolute freedom the site of his garden, its situation, aspect, or area; or, most important of all, he may have to accept, or make some compromise with the soil or sub-soil available for his purpose.



A TYPICAL ROSE GARDEN OF GOOD DESIGN.

Were it possible to stake out one's claim with regard only to the perfect rose garden and without regard to cost, there would, indeed, be no limit to the realisation of the hopes and ambitions of thousands of rose growers.

This, however, is not the true problem before us, which is more commonly the making of a garden within a garden, with all that that implies as to boundaries and restriction of site, sub-soil and other considerations, and to this aspect of the problem I will address myself.

I will therefore talk of the making of a rose garden to those who have already a garden wholly or partly laid out, but wherein roses have, as yet, no place. As the outcome in general measure of a better understanding and appreciation brought about by propaganda, the use of roses mixed up with shrubs and garden plants in large borders is fast disappearing.

It seems at last to be recognised that the rose is entitled to a setting and environment entirely its own, either in beds by themselves, or so detached and featured as pillars, standards and pergolas that their full beauty of colour, setting and habit can receive the fullest appreciation.

Indeed, success leading to success, we find that distinct and separate varieties are appreciated more by being grown in separate beds.

Dealing then first with an old garden, wherein we desire to establish and form a rose garden, my first advice is to take the roses out of the shrubbery beds, and make fresh beds entirely devoted to roses, if possible keeping one variety to each bed.

SOILS.

The question of soil and sub-soil is, perhaps, by far the most vital factor. Admittedly the finest soil for roses is a good, rich loam, preferably with a clay sub-soil, and this undoubtedly forms one of the great secrets of the successful rose growing at Colchester. Gravels and sands are not so good, but they can be made good by deep trenching and a liberal admixture of manure. Chalk soil is about the poorest, although, if one is domiciled upon it, it need not be a deterrent, for it can be saturated with natural and artificial manures, on which the roses will thrive, while the chalk (lime) sub-soil will, by its porosity and nature, prevent the soil from becoming sour.

Such was our experience at Sanderstead, Surrey, where although the soil was less than 18ins. thick above the solid chalk rock, we were able to grow some of the finest exhibition roses. When bringing in fresh soil to make up the beds, be careful of "importing" soil of any description. Our experience in digging beds out in poor chalk soil and substituting a clay base, was a costly failure. In fact, we were fighting against nature, and nature won.

In rose growing, as in agriculture, the law of cropping, or the rotation of crops, applies equally effectively. After roses have been grown in a bed for some years, and a change is desired, entirely fresh soil should be used, as the old will be exhausted and denaturised so far as the latent qualities essential to rose culture are concerned.

Rose nurserymen, growing acres of roses, never plant their briars on the same soil, except at long intervals, and recommend onions as a change crop!

SITUATION.

The best situation and surroundings for a rose garden are where the beds are freely exposed to light and air, but yet are protected against severe winds. Good drainage is, of course, a *sine quâ non*—what rose can grow with feet continually wet and cold?

Shelter from the south-west, our prevalent wind in the south of England, has been recommended, especially for tea roses, but it is not our experience here at Oxted, and we prefer protection from the stormy blasts of the north and north-east winds.

In designing the rose beds they must, in a limited area, be more or less geometrical. For climbers, keep pergolas and arches on the sides of the garden—not in the centre—and bear in mind that the idea of a pergola or rose walk must be to lead from somewhere to somewhere, to give a vista or perspective, and by its nature, while essentially a definite feature, should yet give a sense of distance and space.

The centre, then, would be left open, and cut into beds of various shapes and sizes. Grass paths are infinitely to be preferred to gravel or stone, even though they mean a little more work in upkeep.

The question of selection of the best roses has been so often broached that one hardly likes to recommend, especially knowing that growths vary according to soil, situation, treatment and other considerations. A plebiscite on this subject could not, therefore, even be conclusive, and one can but name the best roses according to one's own experience and individual preference.

Here, on our sandy loam I name:

REDS.—General McArthur, Red Letter Day, Covent Garden and Hawlmark Crimson.

WHITES.—Mrs. Herbert Stevens (T), and Molly Sharman Crawford (T).

PINKS.—Betty Uprichard, Mme. Léon Pain, Ophelia and Lady Pirrie.

YELLOWS.—Mrs. Wemyss Quin, Lady Hillingdon (T), Mabel Morse and Golden Emblem.

The tea roses should be avoided in the case of chalky soils, while on heavy soils roses such as Lieutenant Chauré, Hugh Dickson, etc., will do better.

Experientia docet—one lives one's whole life in learning, and after twenty years of rose growing we still profit by experience, and continually alter our plans and ideas. The advent of new roses is not so much the cause of alterations as might be expected, for most of the good, old-established roses still take a lot of beating, and it is only when outstanding novelties (few and far between though they are) such as Betty Uprichard are put on the market, that an old favourite has to be scrapped to make way for something better.

To the enthusiast thirsting for information as to the growing of roses, and the varieties to be preferred, my advice is to join the R.H.S. and actually study the roses at the Trial Garden at Wisley, Surrey. "Seeing is believing," and one can learn far more in a few hours in that garden than by studying books and catalogues, with long lists of confusing descriptions.

THE WREXHAM DELPHINIUMS

NO better advertisement for the decorative possibilities of the delphinium could possibly be imagined than the great nursery drifts of various first-rate sorts of delphiniums which are to be seen during July and August at Solihull, that noteworthy suburb of Birmingham, and surely no one who has ever seen them can have any doubt, henceforward, that these giant perennial larkspurs are pre-eminently plants for massing.
